# ENCYCLOPÆDIA BRITANNICA.

## P H Y—P H Y.

**PHYLACTERY** (φυλακτήριον), is the name given in the New Testament to the תפילין (tefillin) or "prayer-thongs" of the Jews. Every Jew wears at prayer two of these thongs—(1) the hand-tefilla, a leather thong wound round the left arm and supporting a small case containing a parchment strip with the passages Exod. xiii. 1-10, 11-16, Deut. vi. 4-9, xi. 13-21 written in four columns; (2) the head-tefilla, a similar thong with the four passages inscribed on four separate slips of parchment, and worn round the head so that the box with the texts rests on the forehead. The use of these phylacteries is justified by a literal interpretation of expressions in the passages above cited, and they form, together with the זיזית (zizith) or "fringe" (Numb. xv. 37 sq.) and the mezûza above the door, the three sets of visible signs by which the Israelite is constantly reminded of his duty to God. The zizith is no longer placed on the outer garment as in New Testament times (Matt. xxiii. 5), but on the woollen scarves called תלית (tallith), of which the Jewish man always wears one, while another is wound round the head and neck during prayer. The mezûza is now a longish box fixed over the right doorpost of houses or rooms and containing a parchment with Deut. vi. 4-9, xi. 13-21.

In their origin there can be little doubt that the phylacteries are, according to the proper sense of the Greek word, a kind of amulet, not essentially different from the Aramaic *kmêê*, and in fact "the Hebrew" of the Hexapla uses the word "phylacteries" for the amulets (*E. V.* pillows) of Ezek. xiii. 18. Phylactery and mezûza were supposed to keep off hurtful demons (Targ. on Cant. viii. 3). For further particulars, see Surenhusius, *Mishna*, i. 9 sq., and Bodenschatz, *Kirch. Verf. d. heutigen Juden*, iv. 9 sq.

**PHYLLOXERA.** See VINE.

**PHYSICAL CONSTANTS.** See WEIGHTS AND MEASURES.

**PHYSICAL GEOGRAPHY.** See vol. x. pp. 210-212.

**PHYSICAL SCIENCES.**<sup>1</sup> According to the original meaning of the word, physical science would be that knowledge which is conversant with the order of nature—that is, with the regular succession of events whether

mechanical or vital—in so far as it has been reduced to a scientific form. The Greek word "physical" would thus be the exact equivalent of the Latin word "natural." In the actual development, however, of modern science and its terminology these two words have come to be restricted each to one of the two great branches into which the knowledge of nature is divided according to its subject-matter. Natural science is now understood to refer to the study of organized bodies and their development, while physical science investigates those phenomena primarily which are observed in things without life, though it does not give up its claim to pursue this investigation when the same phenomena take place in the body of a living being. In forming a classification of sciences the aim must be to determine the best arrangement of them in the state in which they now exist. We therefore make no attempt to map out a scheme for the science of future ages. We can no more lay down beforehand the plan according to which science will be developed by our successors than we can anticipate the particular discoveries which they will make. Still less can we found our classification on the order in time according to which different sciences have been developed. This would be no more scientific than the classification of the properties of matter according to the senses by which we have become acquainted with their existence.

It is manifest that there are some sciences, of which we may take arithmetic as the type, in which the subject-matter is abstract, capable of exact definition, and incapable of any variation arising from causes unknown to us which would in the slightest degree alter its properties. Thus in arithmetic the properties of numbers depend entirely on the definitions of these numbers, and these definitions may be perfectly understood by any person who will attend to them. The same is true of theoretical geometry, though, as this science is associated in our minds with practical geometry, it is difficult to avoid thinking of the probability of error arising from unknown causes affecting the actual measurement of the quantities. There are other sciences, again, of which we may take biology as the type, in which the subject-matter is concrete, not capable of exact definition, and subject to the influence of many causes quite unknown to us. Thus in

<sup>1</sup> The paper of the late Professor J. Clerk Maxwell which is presented to the reader under this head was prepared at the time when the ninth edition of the *Encyclopædia Britannica* was being planned, and bore in his MS. the title "Remarks on the Classification of the Physical Sciences."

biology many abstract words such as "species," "generation," &c., may be employed, but the only thing which we can define is the concrete individual, and the ideas which the most accomplished biologist attaches to such words as "species" or "generation" have a very different degree of exactness from those which mathematicians associate, say, with the class or order of a surface, or with the umbilical generation of conicoids. Sciences of this kind are rich in facts, and will be well occupied for ages to come in the co-ordination of these facts, though their cultivators may be cheered in the meantime by the hope of the discovery of laws like those of the more abstract sciences, and may indulge their fancy in the contemplation of a state of scientific knowledge when maxims cast in the same mould as those which apply to our present ideas of dead matter will regulate all our thoughts about living things.

What is commonly called "physical science" occupies a position intermediate between the abstract sciences of arithmetic, algebra, and geometry and the morphological and biological sciences. The principal physical sciences are as follows.

A. *The Fundamental Science of Dynamics, or the doctrine of the motion of bodies as affected by force.*—The divisions of dynamics are the following. (1) *Kinematics*, or the investigation of the kinds of motion of which a body or system of bodies is capable, without reference to the cause of these motions. This science differs from ordinary geometry only in introducing the idea of motion,—that is, change of position going on continuously in space and time. Kinematics includes, of course, geometry, but in every existing system of geometry the idea of motion is freely introduced to explain the tracing of lines, the sweeping out of surfaces, and the generation of solids. (2) *Statics*, or the investigation of the equilibrium of forces,—that is to say, the conditions under which a system of forces may exist without producing motion of the body to which they are applied. Statics includes the discussion of systems of forces which are equivalent to each other. (3) *Kinetics*, or the relations between the motions of material bodies and the forces which act on them. Here the idea of matter as something capable of being set in motion by force, and requiring a certain force to generate a given motion, is first introduced into physical science. (4) *Energetics*, or the investigation of the force which acts between two bodies or parts of a body, as dependent on the conditions under which action takes place between one body or part of a body and another so as to transfer energy from one to the other.

The science of dynamics may be divided in a different manner with respect to the nature of the body whose motion is studied. This forms a cross division. (1) *Dynamics of a particle*; including its kinematics or the theory of the tracing of curves, its statics or the doctrine of forces acting at a point, its kinetics or the elementary equations of motion of a particle, and its energetics, including, as examples, the theory of collision and that of central forces. (2) *Dynamics of a connected system*, including the same subdivisions. This is the most important section in the whole of physical science, as every dynamical theory of natural phenomena must be founded on it. The subdivisions of this, again, are—*a.* dynamics of a rigid system, or a body of invariable form; *b.* dynamics of a fluid, including the discussion (a) of its possible motion, (β) of the conditions of its equilibrium (hydrostatics), (γ) of the action of force in producing motion (hydrodynamics, not so unsatisfactory since Helmholtz, Stokes, and Thomson's investigations), and (δ) of the forces called into play by change of volume; *c.* dynamics of an elastic body; *d.* dynamics of a viscous body.

B. *The Secondary Physical Sciences.*—Each of these

sciences consists of two divisions or stages. In the elementary stage it is occupied in deducing from the observed phenomena certain general laws, and then employing these laws in the calculation of all varieties of the phenomena. In the dynamical stage the general laws already discovered are analysed and shown to be equivalent to certain forms of the dynamical relations of a connected system (*A*, 2), and the attempt is made to discover the nature of the dynamical system of which the observed phenomena are the motions. This dynamical stage includes, of course, several other stages rising one above the other; for we may successfully account for a certain phenomenon, say the turning of a weathercock towards the direction of the wind, by assuming the existence of a force having a particular direction and tending to turn the tail of the cock in that direction. In this way we may account not only for the setting of the weathercock but for its oscillations about its final position. This, therefore, is entitled to rank as a dynamical theory. But we may go on and discover a new fact, that the air exerts a pressure and that there is a greater pressure on that side of the cock on which the wind blows. This is a further development of the theory, as it tends to account for the force already discovered. We may go on and explain the dynamical connexion between this inequality of pressure and the motion of the air regarded as a fluid. Finally, we may explain the pressure of the air on the hypothesis that the air consists of molecules in motion, which strike against each other and against the surface of any body exposed to the air.

The dynamical theories of the different physical sciences are in very different stages of development, and in almost all of them a sound knowledge of the subject is best acquired by adopting, at least at first, the method which we have called "elementary,"—that is to say, the study of the connexion of the phenomena peculiar to the science without reference to any dynamical explanations or hypotheses. Thus we have—

(1) *Theory of gravitation*, with discussion of the weight and motion of bodies near the earth, of the whole of physical astronomy, and of the figure of the earth. There is a great deal of dynamics here, but we can hardly say that there is even a beginning of a dynamical theory of the method by which bodies gravitate towards each other.

(2) *Theory of the action of pressure and heat in changing the dimensions and state of bodies.* This is a very large subject and might be divided into two parts, one treating of the action of pressure and the other of heat. But it is much more instructive to study the action of both causes together, because they produce effects of the same kind, and therefore mutually influence each other. Hence the term "thermodynamics" might be extended to the whole subject were it not that it is already restricted to a very important department relating to the transformation of energy from the thermal to the mechanical form and the reverse. The divisions of the subject are seven. (a) *Physical states of a substance*,—gaseous, liquid, and solid; elasticity of volume in all three states; elasticity of figure in the solid state; viscosity in all three states; plasticity in the solid state; surface-tension, or capillarity; tenacity of solids; cohesion of liquids; adhesion of gases to liquids and solids. (b) *Effects of heat in raising temperature, altering size and form, changing physical state.* (c) *Thermometry.* (d) *Calorimetry.* (e) *Thermodynamics*, or the mutual convertibility of heat and work. (f) *Dissipation of energy by diffusion of matter by mixture, diffusion of motion by internal friction of fluids, diffusion of heat by conduction.* (g) *Theory of propagation of sound, vibrations of strings, rods, and other bodies.*

(3) *Theory of radiance.* (a) *Geometrical optics*; theory of conjugate foci and of instruments. (b) *Velocity*

of light in different media. (c) Prismatic analysis of light,—spectroscopy, radiant heat, visible radiance, ultra-violet rays, calorescence, &c., fluorescence, &c. (d) Colours of thin plates, diffraction, &c. (e) Proof of the existence of wave-lengths and wave-periods (preparation for dynamical theory). (f) Polarized light, radiant heat, &c. (g) The disturbance is transverse to the ray. (h) Quantity of energy in the total radiation from a hot body; Prévost's theory of exchanges, &c. (i) Theory of three primary colours.

(4) Electricity and magnetism. (a) Electrostatics, or distribution and effects of electricity in equilibrium. (b) Electrokinematics, or distribution of currents in conductors. (c) Magnetism and magnetic induction (diamagnetism, &c.). (d) Electromagnetism, or the effects of an electric current at a distance. Under (b) we may discuss electrochemistry, or the theory of electrolysis; under (c) terrestrial magnetism and ship's magnetism; and after (d) comes electrokinetics, or electromagnetic phenomena considered with reference to the fundamental science of dynamics. There is also Faraday's discovery of the effect of magnetism on light and the electromagnetic theory of light.

Chemistry is not included in this list, because, though dynamical science is continually reclaiming large tracts of good ground from the one side of chemistry, chemistry is extending with still greater rapidity on the other side into regions where the dynamics of the present day must put her hand upon her mouth. Chemistry, however, is a physical science, and a physical science which occupies a very high rank.

(J. C. M.)

**PHYSIOGNOMY.** By the Act of Parliament 17 George II. c. 5 all persons pretending to have skill in physiognomy were deemed rogues and vagabonds, and were liable to be publicly whipped, or sent to the house of correction until next sessions.<sup>1</sup> The pursuit thus stigmatized as unlawful is one of great antiquity, and one which in ancient and mediæval times had an extensive though now almost forgotten literature. Physiognomy was regarded by those who cultivated it as a twofold science—(1) a mode of discriminating character by the outward appearance and (2) a method of divination from form and feature. It was very early noticed that the good and evil passions by their continual exercise stamp their impress on the face, and that each particular passion has its own expression. Thus far physiognomy is a branch of physiology, and from a very early age of human thought it attracted philosophic attention. But in its second aspect it touched astrology, of which Galen<sup>2</sup> says that the physiognomical part is the greater, and this aspect of the subject bulked largely in the fanciful literature of the Middle Ages.

The name originated with the Greeks, who called it *φυσιογνωμία*, *φυσιογνωμονία*, or *φυσιογνωμοσύνη*. According to Principal Blackwell<sup>3</sup> of Aberdeen, Homer wrote upon the lines of the hand; but this is not supported by classical authority. That Homer was a close observer of appearance as correlated with character is shown in his description of Thersites<sup>4</sup> and elsewhere. Hippocrates, writing about 450 B.C., refers to this subject, but not in

detail.<sup>5</sup> He believed in the influence of environment in determining disposition, and in the reaction of these upon feature,—a view in which he is supported later by Trogius. Galen speaks of it at more length in his work *Περὶ τῶν τῆς ψυχῆς ἡθῶν*, in which, having discussed the nature and immortality of the soul, he proceeds in chapter vii. to a brief study of physiognomy (ed. Kühn, iv. 795). However, at the end of the chapter he passes over the current physiognomical speculations, saying that he might criticize them but feared to waste time, and become tedious over them. In the eighth chapter he quotes with approbation the Hippocratic doctrine referred to above; and in a later work, *Περὶ κατακλίσεως προγνωστικά*, he speaks of its relations to medicine thus: "Hippocrates igitur, et vetustate admodum notus et scientia admirandus, inquit, 'quocunque exercent medicina, physiognomonie sunt expertes, horam mens in tenebras devoluta torpida senescit,'" &c.<sup>6</sup> We learn both from Iamblichus<sup>7</sup> and Porphyry<sup>8</sup> that Pythagoras was in the habit of diagnosing the characters of candidates for pupilage before admitting them. However, he seems to have discredited the current physiognomy of the schools, as he rejected Cylo the Crotonian from his discipleship on account of his professing these doctrines, and thereby was brought into considerable trouble.<sup>9</sup> Plato also tells us that Socrates predicted the promotion of Alcibiades from his appearance; and Apuleius<sup>10</sup> speaks of Socrates recognizing the abilities of Plato at first view. On the other hand, it has been recorded by Cicero<sup>11</sup> that a certain physiognomist, Zopyrus, who professed to know the habits and manners of men from their bodies, eyes, face, and forehead, characterized Socrates as stupid, sensual, and dull (*bardus*), "in quo Alcibiades cachinnum dicitur sustulisse." Alexander Aphrodisiensis<sup>12</sup> adds that, when his disciples laughed at the judgment, Socrates said it was true, for such had been his nature before the study of philosophy had modified it. Zopyrus is also referred to by Maximus Tyrius<sup>13</sup> as making his recognitions "intuitu solo."

That one's occupation stamps its impress on the outward appearance was also noticed at an early period. In the curious poem in praise of literature found in the Sallier papyrus (II.) in the British Museum this is expatiated on, and the effects of divers handicrafts on the workmen are compared with the elevating influences of a literary life by an Egyptian scribe of the XIIth Dynasty, perhaps 2000 years B.C.<sup>14</sup> Josephus tells us that Cæsar detected the pretence of the spurious Alexander by his rough hands and surface.<sup>15</sup>

The first systematic treatise which has come down to us is that attributed to Aristotle,<sup>16</sup> in which he devotes six chapters to the consideration of the method of study, the general signs of character, the particular appearances characteristic of the dispositions, of strength and weakness,

<sup>5</sup> *Περὶ αἰσθῶν, ὁράων, τέπων* (ed. Kühn, i. 547).

<sup>6</sup> *Op. cit.*, xix. p. 530.

<sup>15</sup> *Ant.*, xvii. 12, 2.

<sup>16</sup> Authors differ in their views as to its authenticity, but Diogenes Laertius (v. 22) and Stobæus (*Serm.*, clxxxix.) both believe it to be genuine. The chief difficulty is the reference to a certain sophist, Dionysius, but this is probably an interpolation. There are physiognomic references in other writings of Aristotle (cf. *Anal. pr.*, ii. c. 30; *Hist. anim.*, i. 8, &c.) sufficient to justify the attribution of the treatise to him. On this, see Franz, Preface, p. vi. sq., of his *Scriptores physiognomiae veteres*, Leipzig, 1780.

<sup>1</sup> The Act 39 Elizabeth c. 4 declared "all persons saying to have knowledge of Physiognomie or like Fantastical Imaginations" liable to "be stripped naked from the middle upwards and openly whipped until his body be bloude." This was modified by 13 Anne c. 26, still further by 17 George II. c. 5, which was re-enacted by 5 George IV. c. 83. This last Act only specifies palmistry.

of genius and stupidity, of timidity, impudence, anger, and their opposites, &c. Then he studies the physiognomy of the sexes, and the characters derived from the different features, and from colour, hair, body, limbs, gait, and voice. He compares the varieties of mankind to animals, the male to the lion, the female to the leopard. The general character of the work may be gathered from the following specimen. While discussing noses, he says that those with thick bulbous ends belong to persons who are insensitive, swinish; sharp-tipped belong to the irascible, those easily provoked, like dogs; rounded, large, obtuse noses to the magnanimous, the lion-like; slender hooked noses to the eagle-like, the noble but grasping; round-tipped retroussé noses to the luxurious, like barn-door fowl; noses with a very slight notch at the root belong to the impudent, the crow-like; while snub noses belong to persons of luxurious habits, whom he compares to deer; open nostrils are signs of passion, &c. Several good editions have been published,<sup>1</sup> and numerous voluminous commentaries written upon it;<sup>2</sup> most subsequent authors have copied from it, with or without acknowledgment. References exist to a work on physiognomy by Theophrastus, but it is not extant; and the next important author is Melampus, the Egyptian hierogrammateus, who lived at the court of Ptolemy Philadelphus, and wrote, about 270 B.C., the work *Περὶ παλῶν μαντικῆς*. This, while descriptive, like that of Aristotle, deals largely in omens, in divination from nævi and the twitchings of limbs. It was edited by Camillus Peruscius, and published at Rome (1545) along with those of Polemon and Adamantius.<sup>3</sup> References to physiognomy are to be found in many of the Greek classics.<sup>4</sup> Apion speaks of the metoposcopists who judge by the appearance of the face, and Cleanthes the Stoic says it is possible to tell habits from the aspect (cf. *Ecclus.* xix. 29, 30). Polemon (c. 150 A.D.) is the next in order who has left a treatise on the subject, similar in character to that of Aristotle; but he excels in graphic descriptions of different dispositions and differs only from Aristotle in some of his animal comparisons. The best modern edition of his work is contained in Franz's *Scriptores physiognomiae veteres*. It was translated into Latin and published at Venice by Nicholas Petreius in 1534. This book was referred to by Albertus Magnus, who attributes to its author a second work on the subject. A more important contribution to the literature of physiognomy was added by a converted Jew, Adamantius, about 415. This work is in two books, the first on the expression of the eye, the second on physiognomy in general, mostly Aristotelian in character. He professes to have learned much from the Egyptians, and tells us that nature speaks in the forehead and face and in the silence of the mouth. He follows Aristotle in holding rather a low opinion of the intellect of the female sex, whom he makes the subject of some rather depreciating comparisons. His work was edited with the foregoing by Franz.<sup>5</sup> Artemidorus, Loxus, Philemon, Posidonius,<sup>6</sup> Con-

stantinus,<sup>7</sup> are other early authors frequently quoted by 16th-century writers, while Phemonoe, Antiphon, Helenus of Syracuse, and Eunolpins are mentioned as writers by Porta, Albertus Magnus, and others, but their works are not extant.

The Latin classics occasionally refer to physiognomy: Juvenal (vi. 383) speaks of the examination of forehead and face, but not with much respect; Suetonius (*Vita Titi*, 2) tells us, "Quo quidem tempore, aiunt, metoposcopum a Narcisso, Claudio liberto, adhibitum, ut Britannicus inspicret"; and Pliny also refers to it (*H. N.*, xxxv. 10). References also exist in the writings of Clement of Alexandria; and Origen,<sup>8</sup> while speaking of the Jewish fable as to the birth of Christ, asks, Is it possible, if there be any truth in the science taught by Zopyrus, Loxus, and Polemon, that such a soul as Christ's could have been provided with a suitable body in such a way? Sir George Wharton quotes the text Job xxxvii. 7, "He impresseth (ἑκτυπῶν) the hand of every man, that all may know His work," as an authority for chiromancy, and other chiromantists have followed him in so doing.<sup>9</sup>

Hitherto the physiognomy of the schools had been chiefly descriptive; in the succeeding period the astrological side, whose gradual development may be noted, becomes the most important part. Hence in the subsequent or second stage of history chiromancy is specially predictive in character, and attains an importance it had not originally possessed. The treatises also contain occasional digressions on onychomancy, alektoromancy, elidomancy, coccinomancy, podoscopy, sparmatomancy, &c.

Along with the medical science of the period the Arabians took up the study of physiognomy: 'Alī b. Ragel wrote a book on nævi; Rhazes (1040) devoted several chapters of his medical work to it; and Averroes (1165) made many references to it in his *De Sanitate* (p. 82, Leyden, 1537). Avicenna also makes some acute physiognomical remarks in his *De Animalibus*, which was translated by Michael Scott about 1270, but printed subsequently (without date or place). Albertus Magnus (born 1205) devotes much of the second tract of his *De Animalibus* to the consideration of physiognomy. There is, however, nothing original in the treatise, which largely consists of extracts from Aristotle, Polemon, and Loxus. He does not enter so much into the animal comparisons of his predecessors, but occupies himself chiefly with simple descriptive physiognomy as indicative of character; and the same is true of the many scattered notes in the writings of Duns Scotus and Thomas Aquinas. The famous sage of Balwearie, Michael Scott, while court astrologer to the emperor Frederick II., wrote his treatise *De hominis phisionomia* (c. 1272), much of which is physiological and of curious interest. It was not printed until 1477, and the edition was not illustrated. The physiognomical treatise forms the third part of his work *De secretis naturæ*. In 1335 Petrus de Abano of Padua delivered in Paris a course of lectures on this subject (afterwards edited by Blondus, 1544), a few years before he was burned for heresy. Shortly after the introduction of printing in the 15th century a large number of works on physiognomy were produced; probably the oldest is the block book by Hartlieb, *Die Kunst Ciromantia*. This is an exceedingly rare folio, of which one fine copy is extant in Paris; each page bears a figure of a giant hand from 7 to 10½ inches long, inscribed with characteristic words, and with a small amount of description below; there are twenty-seven such

<sup>1</sup> That of J. G. Franz (Leipzig, 1780) is the best; Andreas Lacuna published a Latin version, Paris, 1535; Willichius, another at Wittenberg, 1538.

<sup>2</sup> Fontain's *Commentary* (Paris, 1611), Camillus Baldus of Bologna (1621), Sanchez of Toulouse (1636).

<sup>3</sup> And later by Franz (*op. cit.*, p. 470).

<sup>4</sup> See an interesting paper on "Stretching and Yawning as Signs of Madness," by Professor Ridgeway (*Trans. Camb. Philol. Soc.*, vol. i. p. 210), which refers to Aristoph., *Wasps*, 642, with which he compares Plautus, *Menæchmi*, 279. Other references exist to physiognomy in Cassiodorus, Isidorus, Meletius, and Nemesius, but none of any very great importance.

<sup>5</sup> It was edited by Janus Cornaro at Marburg, 1543, by Bonum of Paris ten years later, by Camillus Peruscius, by Petreius, and by Sylburg in the sixth volume of his *Aristotellæ*.

<sup>6</sup> *Περὶ παλῶν*. See Justin Martyr's *Quæst. ad orthodox.*, xix., vol. ii., Paris, 1742, p. 461.

<sup>8</sup> *Contra Celsum*, i. 38.

<sup>9</sup> For other references to Scriptural allusions to physiognomy, see Vecchius, *Observationes in div. script.*, Naples, 1641.

plates. A description of another perfect copy belonging to Earl Spencer occurs in Dibdin's *Bibliographical Decameron* (1817), vol. i. p. 143, and four imperfect copies are known to exist elsewhere. The date of Hartlieb's work is probably 1470. This and Michael Scott's books were the first printed works on the subject.

The 16th century was particularly rich in publications on physiognomy. Not only were the classical works printed, but additions were made to the literature by Cocles, Corvus, Johannes de Indagine, Cornaro, Blondus, Douxciel, Pompeius Ronnseus, Gratarolus, Niquetius, Pomponius Gauricus, Tricassus, Cardan, Tiberius, Thaddæus ab Hayck, Taisnieres, Rizzacasa, Campanella, Hund, Picciolus, Rothman, Johannes Padovanus, and, last and greatest of all, Giambattista della Porta. Several works also appeared in England, the earliest being the anonymous *On the Art of foretelling Future Events by Inspection of the Hand* (London, 1504). A second anonymous work, *A pleasant Introduction to the Art of Chiromancie and Physiognomie*, was published at the same place in 1558. Neither of these is of any merit. The first English work with the author's name is that of Dr Thomas Hill (1571), *The Contemplation of Mankynde, contayning a singular Discourse after the Art of Phisognomie*. This is rather quaintly written, but is simply an adaptation from the Italian writers of the day. Another anonymous author about this period, but whose work has no date, writes, under the name "Merlin Britannicus," upon moles and nævi after the model of 'Alf b. Ragel. The word "physiognomy" had been introduced into England before this century, and, from analogy with the Greek, had been used in the sense of the outward appearance, or the face: thus in Udall's translation of the paraphrase of Erasmus on Mark iv. it occurs spelt "phisnomi"; the pugnacious bishop of Osory, Bale, in his *English Votaries*, spells it "physnomie" (pt. i. ch. ii. p. 44).

The rise of the study of anatomy served largely to bring physiognomy into discredit by substituting real facts for fictions; hence in the 17th century its literature, while not smaller in quantity, was less important in quality. The principal authors are Goclenius, Fuchs, Timpler, Tischbein, Gallimard, Moldenarius, Septalius, Hertod, Scarlatini, Saunders, Withers, Helvetius, Lebrun, Elsholtius, De la Bellière, Philipp May, Evelyn, Freius, Baldus, Torreblanca, Otto, Bulwer, Rhyne, Merbitzius, Fludd, Zanardus, Finella, Tamburini, Etzler, Vecchius, Prætorius, De la Chambre, and Giraldu.

The 18th century shows a still greater decline of interest in physiognomy. Historians of philosophy, like Meursius and Franz, re-edited some of the classical works, and Fülleborn reviewed the relation of physiognomy to philosophy. Indeed the only name worthy of note is that of LAVATER (q.v.). The other authors of this century are Peuschel, Spon, Lichtenberg, Schutz, Wegelin, Pernetty, Girtanner, Grohmann, and several anonymous writers, and from the anatomical side Lancisi, Parsons, and Peter Camper. The popular style, good illustrations, and pious spirit pervading the writings of Lavater have given to them a popularity they little deserved, as there is really no system in his work, which largely consists of rhapsodical comments upon the several portraits. Having a happy knack of estimating character, especially when acquainted with the histories of the persons in question, the good pastor contrived to write a graphic and readable book, but one much inferior to Porta's or Aristotle's as a systematic treatise. With him the descriptive school of physiognomists may be said to have ended, as the astrological physiognomy expired with De la Bellière. The few straggling works which have since appeared are scarcely deserving of notice, the rising attraction of phrenology having given to pure physiognomy the *coup de grâce* by taking into itself whatever

was likely to live of the older science. The writers of this century are Hörsting, Maas, Rainer, Cross, Stöhr, Sehler, Diez, Carus, Piderit, Burgess, and Gratiolet.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, as his *Essay on the Anatomy of Expression*, published in 1806, was the first really scientific study of expression. He was one of the first who accurately correlated the motions expressive of the passions with the muscles which produce them, and in the later editions of his work these descriptions are much enlarged and improved. Shortly after the appearance of the first edition of Bell's *Essay* Moreau published his first edition of Lavater along somewhat the same lines (1807). The experiments of Duchenne (*Mécanisme de la Physionomie Humaine*, Paris, 1862) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. These tested and confirmed by experimental demonstration the hypothetic conclusions of Bell. The machinery of expression having thus been clearly followed out, the correlation of the physical actions and the psychical states was made the subject of speculation by Spencer (*Psychology*, 1855), and such speculations were first reduced to a system by Darwin (*Expression of Emotions*, 1872), who formulated and illustrated the following as fundamental principles.

(1) Certain complex acts are of direct or indirect service under certain conditions of the mind in order to relieve or gratify certain sensations or desires; and whenever the same state of mind is induced the same set of actions tend to be performed, even when they have ceased to be of use. (2) When a directly opposite state of mind is induced to one with which a definite action is correlated, there is a strong and involuntary tendency to perform a reverse action. (3) When the sensorium is strongly excited nerve-force is generated in excess, and is transmitted in definite directions, depending on the connexions of nerve-cells and on habit.

It follows from these propositions that the expression of emotion is for the most part not under the control of the will, and that those striped muscles are the most expressive which are the least voluntary. The philosophy of physiognomy may be formulated upon this definite theoretic basis. (1) The actions we look upon as expressive of emotions are such as at some time were serviceable in relieving or gratifying the desires or sensations accompanying the emotion. (2) Such actions become habitually associated with the mental condition and continue even where their utility is lost. (3) Certain muscles which produce these actions become from habitual action strengthened, and, when the skin diminishes in fulness and elasticity with advancing age, the action of the muscle produces furrows or wrinkles in the skin at right angles to the course of the fibres of the muscle. (4) As the mental disposition and proneness to action are inherited by children from parents, so the facility and proneness to expression are similarly developed under the law of heredity. (5) To some extent habitual muscular action and the habitual flow of nerve-force in certain directions may alter the contour of such bones and cartilages as are thereby acted upon by the muscles of expression. Illustrations of these theoretic propositions are to be found in the works of Bell, Duchenne, and Darwin, to which the student may be referred for further information.

For information on artistic anatomy as applied to physiognomy see the catalogue of sixty-two authors by Ludwig Choulant, *Geschichte und Bibliographie der anatomischen Abbildung*, &c., Leipzig, 1852, and the works of the authors enumerated above, especially those of Aristotle, Franz, Porta, Cardan, Corvus, and Bulwer. An attempt has been made recently to rehabilitate palmistry by D'Arpentigny and Desbarrolles, for summaries of which see the works of Beamish and Craig. For physiognomy of disease, besides the usual medical handbooks, see Cabuchet, *Essai sur l'Expression de la Face dans les Maladies*, Paris, 1801. For ethnological physiognomy, see amongst older authors Gratarolus and amongst moderns the writers cited in the various text-books on anthropology. (A. M.A.)

PHYSIOLOGUS, the most common title of a collection of some fifty Christian allegories much read in the Middle Ages, and still existing in several forms and in about a dozen Eastern and Western languages. As nearly all its imagery is taken from the animal world, it is also known as the *Bestiary*. There can be hardly a doubt about the time and general circumstances of its origin. Christian teachers, especially those who had a leaning towards gnostic speculations, took an interest in natural history, partly because of certain passages of Scripture that they wanted to explain, and partly on account of the divine revelation in the book of nature, of which also it was man's sacred duty to take proper advantage. Both lines of study were readily combined by applying to the interpretation of descriptions of natural objects the allegorical method adopted for the interpretation of Biblical texts. Now the early Christian centuries were anything but a period of scientific research. Rhetorical accomplishments were considered to be the chief object of a liberal education, and to this end every kind of learning was made subservient. Instead of reading Aristotle and other naturalists, people went for information to commonplace books like those of *Ælian*, in which scraps of folk-lore, travellers' tales, and fragments of misapprehended science were set forth in an elegant style for the enjoyment of the general reader. Theological writers with a merely literary training were not in the least prepared to question the worth of the marvellous descriptions of creatures that were current in the schools on the faith of authorities vaguely known as "the history of animals," "the naturalists," and "the naturalist" in the singular number (*φυσιολόγος*).<sup>1</sup> So they took their notions of strange beasts and other marvels of the visible world on trust and did their best to make them available for religious instruction. In some measure we find this practice adopted by more than one of the fathers, but it was only natural that the Alexandrian school, with its pronounced taste for symbolism, should make the most of it. Clement himself had declared that natural lore, as taught in the course of higher Christian education according to the canon of truth, ought to proceed from "cosmogony" to "the theological idea,"<sup>2</sup> and even in the little that is left of the works of Origen we have two instances of the proceeding in question. And yet the fact that these reappear in the *Physiologus* would not suffice to stamp the work as a series of extracts from Alexandrian writings, as parallels of the same kind can be adduced from Epiphanius (*loc. cit.*) and Ephraem Syrus (*Opp. Syr.*, ii. pp. 17, 130). Father Cahier would even trace the book to Tatian, and it is true that that heresiarch mentions a writing of his own upon animals. Still the context in which the quotation occurs makes it evident that the subject-matter was not the nature of particular species nor the spiritual lessons to be drawn therefrom, but rather the place occupied by animal beings in the system of creation. On the other hand, the opinion of Cardinal Pitra, who referred the *Physiologus* to the more orthodox though somewhat peculiar teaching of the Alexandrians, is fully borne out by a close examination of the irregularities of doctrine pointed out in the *Physiologus* by Cahier, all of which are to be met with in Origen. The technical words by which the process of allegorizing is designated in the *Physiologus*, like *ἐρμηνεία*, *θεωρία*, *ἀναγωγή*, *ἀλληγορία*, are familiar to the students of Alexandrian exegesis. It

<sup>1</sup> Origen, *Sol. in Jerem.*, xvii. 11, "ἐν τῇ περὶ ζώων ιστορίᾳ"; Epiphanius, *Adv. Hær.*, i. 3, p. 274 (ed. D. Petar.), "ὡς φασὶν οἱ φυσιολόγοι"; Origen, *Hom.* xvii., in Gen. xlii. 9, "nam physiologus de castulo leonis scribit."

<sup>2</sup> *Strom.*, iv. p. 564 (ed. Potter), ἡ γοῦν κατὰ τὸν τῆς ἀληθείας καὶ τῆς γνῶσεως παραδόσεως φυσιολογία, μᾶλλον δὲ ἐκκοιμήτα, ἐκ τοῦ περὶ κοσμογονίας ἡρώτηται λόγου, ἐνθενδε ἀναβαίνοντα ἐπὶ τὸ θεολογικὸν εἶδος.

has, moreover, been remarked that almost all the animals mentioned were at home in the Egypt of those days, or at least, like the elephant, were to be seen there occasionally, whereas the structure of the hedgehog, for instance, is explained by a reference to the sea-porcupine, better known to fish-buyers on the Mediterranean. The fables of the phoenix and of the conduct of the wild ass and the ape at the time of the equinox owe their origin to astronomical symbols belonging to the Nile country.<sup>3</sup> In both chapters an Egyptian month is named, and elsewhere the antelope bears its Coptic name of "antholops."

That the substance of the *Physiologus* was borrowed from commentaries on Scripture<sup>4</sup> is confirmed by many of the sections opening with a text, followed up by some such formula as "but the *Physiologus* says." When zoological records failed, Egypto-Hellenic ingenuity was never at a loss for a fanciful invention distilled from the text itself, but which, to succeeding copyists, appeared as part of the teaching of the original *Physiologus*. As a typical instance we may take the chapter on the ant-lion,—not the insect, but an imaginary creature suggested by Job iv. 11. The exceptional Hebrew for a lion (*layish*) appeared to the Septuagint translators to call for a special rendering, and as there was said to exist on the Arabian coast a lion-like animal called "myrmex" (see Strabo, xvi. p. 774; *Ælian*, *N. A.*, vii. 47) they ventured to give the compound noun "myrmekoleon." After so many years the commentators had lost the key to this unusual term, and only knew that in common Greek "myrmex" meant an ant. So the text "the myrmekoleon hath perished for that he had no nourishment" set them pondering, and others reproduced their meditations, with the following result: "The *Physiologus* relates about the ant-lion: his father hath the shape of a lion, his mother that of an ant; the father liveth upon flesh, and the mother upon herbs. And these bring forth the ant-lion, a compound of both, and in part like to either, for his fore part is that of a lion, and his hind part like that of an ant. Being thus composed, he is neither able to eat flesh like his father, nor herbs like his mother; therefore he perisheth from inanition"; the moral follows.

At a later period, when the church had learnt to look with suspicion upon devotional books likely to provoke the scoffing of some and lead others into heresy, a work of this kind could hardly meet with her approval. A synod of Pope Gelasius, held in 496, passed censure, among others, on the "Liber Physiologus, qui ab hæreticis conscriptus est et B. Ambrosii nomine signatus, apocryphus," and evidence has even been offered that a similar sentence was pronounced a century before. Still, in spite of such measures, the *Physiologus*, like the *Church History* of Eusebius or the *Pastor of Hermas*, continued to be read with general interest, and even Gregory the Great did not disdain to allude to it on occasion. Yet the Oriental versions, which had certainly nothing to do with the Church of Rome, show that there was no systematic revision made according to the catholic standard of doctrine. The book remained essentially the same, albeit great liberties were taken with its details and outward form. There must have been many imperfect copies in circulation, from which people transcribed such sections as they found or chose, and afterwards completed their MS. as occasion served. Some even rearranged the contents according to the alphabet or to zoological affinity. So little was the collection considered as a literary work with a definite text that every one assumed a right to abridge or enlarge, to insert ideas of his

<sup>3</sup> Cp. Leemans on Horapollo, i. 16, 34.

<sup>4</sup> Including the Apocrypha. See the Icelandic account of the elephant, also a decidedly Alexandrian fragment upon the *μάργος*, founded upon 4 Maccab. i. 3, which has got into the scholia upon the *Odyssey*, xviii. 2 (ii. p. 533, ed. Dindorf, Oxford, 1855).

own, or fresh Scriptural quotations; nor were the scribes and translators by any means scrupulous about the names of natural objects, and even the passages from Holy Writ. *Physiologus* had been abandoned by scholars, and left to take its chance among the tales and traditions of the uneducated mass. Nevertheless, or rather for this very reason, its symbols found their way into the rising literature of the vulgar tongues, and helped to quicken the fancy of the artists employed upon church buildings and furniture.

The history of the *Physiologus* has become entwined from the beginning with that of the commentaries on the account of creation in Genesis. The principal production of this kind in our possession is the *Hexameron* of Basil, which contains several passages very like those of the *Physiologus*. For instance, in the seventh homily the fable of the nuptials of the viper and the conger-eel, known already to Ælian and Oppian, and proceeding from a curious misreading of Aristotle (*Hist. An.*, v. 4, p. 540 b, Bekk.), serves to point more than one moral. Notwithstanding the difference in theology, passages of this kind could not but be welcome to the admirers of the Alexandrian allegories. In fact a medley from both Basil and the *Physiologus* exists under the title of the *Hexameron* of Eustathius; some copies of the first bear as a title *Περὶ φυσιολογίας*, and in a Milan MS. the "morals" of the *Physiologus* are ascribed to Basil. The Leyden Syriac is supplemented with literal extracts from the latter, and the whole is presented as his work. Other copies give the names of Gregory Theologus, Epiphanius, Chrysostom, and Isidore.

As far as can be judged, the emblems of the original *Physiologus* were the following: (1) the lion (footprints rubbed out with tail; sleeps with eyes open; cubs receive life only three days after birth by their father's breath); (2) the sun-lizard (restores its sight by looking at the sun); (3) the charadrius (*Deut.* xiv. 16; presages recovery or death of patients); (4) the pelican (recalls its young to life by its own blood); (5) the owl (or nyktikorax; loves darkness and solitude); (6) the eagle (renews its youth by sunlight and bathing in a fountain); (7) the phoenix (revives from fire); (8) the hoopoe (redeems its parents from the ills of old age); (9) the wild ass (suffers no male besides itself); (10) the viper (born at the cost of both its parents' death); (11) the serpent (sheds its skin; puts aside its venom before drinking; is afraid of man in a state of nudity; hides its head and abandons the rest of its body); (12) the ant (orderly and laborious; prevents stored grain from germinating; distinguishes wheat from barley on the stalk); (13) the sirens and onocentaurs (*Isa.* xiii. 21, 22; compound creatures); (14) the hedgehog (pricks grapes upon its quills); (15) the fox (catches birds by simulating death); (16) the panther (spotted skin; enmity to the dragon; sleeps for three days after meals; allures its prey by sweet odour); (17) the sea-tortoise (or aspidochelone; mistaken by sailors for an island); (18) the partridge (hatches eggs of other birds); (19) the vulture (assisted in birth by a stone with loose kernel); (20) the ant-lion (able neither to take the one food nor to digest the other); (21) the weasel (conceives by the mouth and brings forth by the ear); (22) the unicorn (caught only by a virgin); (23) the beaver (gives up its testes when pursued); (24) the hyæna (a hermaphrodite); (25) the otter (enhydris; enters the crocodile's mouth to kill it); (26) the ichneumon (covers itself with mud to kill the dragon; another version of No. 25); (27) the crow (takes but one consort in its life); (28) the turtle-dove (same nature as No. 27); (29) the frog (either living on land and killed by rain, or in the water without ever seeing the sun); (30) the stag (destroys its enemy the serpent); (31) the salamander (quenches fire); (32) the diamond (powerful

against all danger); (33) the swallow (brings forth but once; misreading of Aristotle, *Hist. An.*, v. 13); (34) the tree called peridexion (protects pigeons from the serpent by its shadow); (35) the pigeons (of several colours; led by one of them, which is of a purple or golden colour); (36) the antelope (or hydrissus; caught by its horns in the thicket); (37) the fire-flints (of two sexes; combine to produce fire); (38) the magnet (adheres to iron); (39) the saw-fish (sails in company with ships); (40) the ibis (fishes only along the shore); (41) the ibex (descries a hunter from afar); (42) the diamond again (read "carbuncle"; found only by night); (43) the elephant (conceives after partaking of mandrake; brings forth in the water; the young protected from the serpent by the father; when fallen is lifted up only by a certain small individual of its own kind); (44) the agate (employed in pearl-fishing); (45) the wild ass and ape (mark the equinox); (46) the Indian stone (relieves patients of the dropsy); (47) the heron (touches no dead body, and keeps to one dwelling-place); (48) the sycamore (or wild fig; grubs living inside the fruit and coming out); (49) the ostrich (devours all sorts of things; forgetful of its own eggs). Besides these, or part of them, certain copies contain sections of unknown origin about the bee, the stork, the tiger, the woodpecker, the spider, and the wild boar.

The Greek text of the *Physiologus* exists only in late MSS., and has to be corrected from the translations. In Syriac we have a full copy in a 12th-century Leyden MS., published in J. P. N. Land's *Anecdota Syriaca*; thirty-two chapters with the "morals" left out in a very late Vatican copy, published by Tychsen; and about the same number in a late MS. of the British Museum (Add. 25878). In Armenian Pitra gave some thirty-two chapters from a Paris MS. (13th century). The *Æthiopie* exists both in London and Paris, and was printed at Leipsic by Dr Hommel in 1877. In Arabic we have fragments at Paris, of which Renan translated a specimen for the *Spicilegium Solesmense*, and another version of thirty-seven chapters at Leyden, probably the work of a monk at Jerusalem, which Land translated and printed with the Syriac. The Latin MSS. of Bern are, after the Vatican glossary of Ansilenbus, the oldest of which we know; there are others in several libraries, and printed editions by Mai, Heider, and Cahier. Besides these a few fragments of an old abridgment occur in Vallarsi's edition of Jerome's works (vol. xi. col. 218). A metrical *Physiologus* of but twelve chapters is the work of Theobaldus, probably abbot of Monte Cassino (1022-1035 A.D.). From this was imitated the Old-English fragment printed by Th. Wright, and afterwards by Maetzner; also the Old-French *Sceneyl le bestiaire d'amours*. The prose *Physiologus* was done into Old High German before 1000, and afterwards into rhyme in the same idiom; since Von der Hagen (1824) its various forms have found careful editors among the leading Germanists. The Icelandic, in a Copenhagen MS. of the 13th century, was printed by Prof. Th. Möbius in his *Analecta norroena* (2d ed., 1877); at the same time he gave it in German in Dr Hommel's *Æthiopie* publication. Some Anglo-Saxon metrical fragments are to be found in Grein's *Bibliothek*, vol. i. The Provençal (c. 1250), published in Bartsch's *Chrestomathie provençale*, omits the "morals," but is remarkable for its peculiarities of form. Before this there had been translations into French dialects, as by Philippe de Thaurin (1121), by Guillaume, "clerc de Normandie," also, about the same period, by Pierre, a clergyman of Picardy. All the Old-French materials have not yet been thoroughly examined, and it is far from improbable that some versions of the book either remain to be detected or are now lost past recovery. A full account of the history of the *Physiologus* should also embrace the subjects taken from it in the productions of Christian art, the parodies suggested by the original work, e.g., the *Bestiaire d'Amour* by Richard de Fournival, and finally, the traces left by it upon the encyclopædical and literary work of the later Middle Ages.

Nearly all the information now obtainable is to be found in the following works, and such as are there quoted: S. Epiphanius ad *Physiologum*, ed. Ponce de Leon, Rome, 1587 (with woodcuts); another edition, Antwerp, 1588 (with copper-plates); S. Eustathii in *Hexameron* Commentarius, ed. Leo Allatius, Lyons, 1629 (cp. H. van Herwerden, *Exercit. Crit.*, Lingue, 1862, pp. 180-182); *Physiologus Syrus*, ed. O. G. Tychsen, Rostock, 1793; *Classici Auctores*, ed. Mai, vol. vii., Rome, 1835, pp. 585-596; G. Heider, in *Archiv für Kunde Österreich. Geschichtsquellen*, Vienna, 1850, vol. ii. p. 545 sq.; Cahier and Martin, *Mélanges d'Archéologie*, &c., vol. ii., Paris (1851), p. 85 sq., vol. iii. (1853), p. 201 sq., vol. iv. (1856), p. 55 sq.; Cahier, *Nouveaux Mélanges* (1874) p. 106 sq.; J. B. Pitra, *Spicilegium Solesmense*, vol. iii., Paris, 1855, pp. xlviii. sq., 325 sq., 416. 2. 3; Maetzner, *Allengl. Sprachproben*, vol. i. pt. i., Berlin, 1867, p. 55 sq.; J. Victor Carus, *Gesch. der Zoologie*, Munich, 1872, p. 109 sq.; J. P. N. Land, *Anecdota Syriaca*, vol. iv., Leyden, 1874, p. 31 sq., 115 sq., and in *Verlag von Meibner und Hommel* in their publications quoted above. (J. P. N. L.)

# PHYSIOLOGY

## PART I.—GENERAL VIEW.

THE word "physiology" may be used either in a general or in a more restricted sense. In its more general meaning it was used largely of old, and is still occasionally used in popular writings, to denote all inquiry into the nature of living beings. A very slight acquaintance, however, with the phenomena of living beings shows that these can be studied from two, apparently very different, points of view.

The most obvious and striking character of a living being is that it appears to be an agent, performing actions and producing effects on the world outside itself. Accordingly, the first efforts of inquirers were directed towards explaining how these actions are carried on, how the effects of a living being upon its surroundings are brought about. And the dissection or pulling to pieces of the material body of a living being was, under the name of ANATOMY (q.v.), regarded as simply an analysis preparatory and necessary to the understanding of vital actions. But it soon became obvious that this anatomical analysis gave rise of itself to problems independent of, or having only distant relations to, the problems which led to do with the actions of living beings. Hence in course of time a distinct science has grown up which deals exclusively with the laws regulating the form, external and internal, of living beings, a science which does not seek to explain the actions of living beings, and takes note of these actions only when they promise to throw light on the occurrence of this or that structural feature. Such a science, which is now known under the name of MORPHOLOGY (q.v.), might be carried on in a world in which all living things had, in the ordinary meaning of the word, become dead. Were the whole world suddenly petrified, or were a spell to come over it like that imagined by Tennyson in his "Day Dream," but more intense, so that not only the gross visible movements but the inner invisible movements which are at the bottom of growth were all stayed, the morphologist would still find ample exercise for his mind in investigating the form and structure of the things which had been alive, and which still differed from other things in their outward lineaments and internal build.

nary analysis of the phenomena of action of a living being, —for instance of one of the more complex, so-called higher animals, such as man—he might proceed in some such way as the following.

One of the first, perhaps the first and most striking fact about man is that he moves: his body moves of itself from place to place, and one part of the body moves on another. If we examine any one of these movements, such as the bending of the forearm on the arm, we find that it is brought about by certain masses of flesh, called muscles, which from time to time contract, that is, shorten; and these muscles are so disposed that, when they shorten, and so bring their ends nearer together, certain bones are pulled upon and the arm is bent. Upon further examination it will be found that all the gross movements of the body, both the locomotion of the whole body and the movements of parts upon parts, are carried out by the contraction or shortening of muscles. The muscles, together with bones, tendons, and other structures, are arranged in various mechanical contrivances, many of them singularly complex; hence the great diversity of movement of which an animal or man is capable; but in all cases the central fact, that which supplies the motive-power, is the contraction of a muscle, a shortening of its constituent fibres whereby its two ends are brought for a while nearer together.

When, pushing the analysis farther, we attempt to solve the question, Why do muscles contract? we find that the muscles of the body are connected with what is called the central nervous system by certain strands of living matter called nerves; and we further find that, with some few exceptions, which need not concern us now, the contractions of muscles are brought about by certain occult invisible changes called nervous impulses which travel along these nerves from the central nervous system to the muscles. Hence, when a nerve is severed, the muscle to which the nerve belonged, thus cut adrift from the central nervous system, no longer stirred by impulses reaching it from thence, ceases to contract, and remains motionless and as it were helpless. Pushing the problem still farther home, and asking how these impulses originate in the central nervous system, we find that this central nervous mass is connected, not only with the muscles by means of nerves which, carrying impulses outward from itself to the muscles and so serving as instruments of movement, are called motor or efferent nerves, but also with various surfaces and parts of the body by means of other nerves, along which changes or impulses travel inwards to itself in a centripetal fashion. Moreover, the beginnings or peripheral endings of these other nerves appear to be so constituted that various changes in the surroundings of the body, or internal changes in the body itself, give rise to impulses, which, thus originated, travel inwards to the central nervous system; hence these nerves are spoken of as sensory or afferent. Such sensory impulses reaching the central nervous system may forthwith issue as motor impulses leading to movement; but on many occasions they tarry within the central mass, sweeping backwards and forwards along particular areas of its substance, thus maintaining for a while a state of molecular agitation and leading to movement at some subsequent period only. Moreover, we have reason to think that molecular disturbances may arise within the central nervous system apart from the advent, either past or present, of any impulses along sensory nerves. Lastly, the presence of these molecular agitations in the central

nervous system, whether the immediate result of some new afferent impulse, or the much delayed and complicated outcome of some impulse which arrived long ago, or the product of internal changes apparently independent of all disturbance from without and so far spontaneous, may be indicated by corresponding phases of what we speak of as consciousness. We are thus led to conceive of the central nervous system as, chiefly at least, the seat of a molecular turmoil maintained by multitudinous afferent impulses streaming in along the various afferent nerves, a turmoil which makes itself felt within as changes of consciousness, and produces effects without by movements wrought through motor nerves and muscles. And one large part of physiology has for its task the unravelling of the laws which govern this turmoil, which determine, in relation to the advent of afferent impulses and the occurrence of intrinsic changes, the issue of motor impulses, and thus the characters of the resulting movements.

**Chemical changes.** The movements of man or of an animal are not, however, the only salient facts of his existence. Equally characteristic of him are the facts, (1) that he from time to time eats, and must eat in order to live, and (2) that a supply of fresh air containing a certain quantity of oxygen is indispensable to his remaining alive. Viewed from a chemical point of view, an animal body, whether dead or alive, is a mass of complex unstable chemical substances, combustible in nature, i.e., capable of being oxidized, and of being reduced by oxidation to simpler, more stable substances, with a setting free of energy. Combustible in the ordinary sense of the word an animal body is not, by reason of the large excess of water which enters into its composition; but an animal body thoroughly dried will in the presence of oxygen burn like fuel, and, like fuel, give out energy as heat. The material products of that combustion are fairly simple, consisting of water, carbonic acid, some ammonia or nitrogen compounds, and a few salts. And these same substances appear also as the products of that slower combustion which we call decay; for, whether the body be burnt swiftly in a furnace or rot away slowly in earth, air, or water, the final result is the same, the union of the complex constituent substances with the oxygen furnished from the air, and their reduction thereby to the above-named products, with a development of heat, which either as in the first case is rapid and appreciable, or as in the second is so slow and gradual as to be with difficulty recognized. Moreover, during life also the same conversion, the same oxidation, the same reduction of complex substances to simpler matters, the same setting free of the energy present in the former but absent in the latter, may be noted. The animal body dies daily, in the sense that at every moment some part of its substance is suffering decay, is undergoing combustion; at every moment complex substances full of latent energy are by processes of oxidation reduced to simpler substances devoid of energy or containing but little.

**Source of bodily energy.** This breaking down of complex substances, this continued partial decay, is indeed the source of the body's energy; each act of life is the offspring of an act of death. Each strain of a muscle, every throb of the heart, all the inner work of that molecular turmoil of the nervous system of which we spoke above, as well as the chemical labour wrought in the many cellular laboratories of glands and membranes, every throw of the vital shuttle, means an escape of energy as some larger compacted molecule splits into smaller simpler pieces. Within the body the energy thus set free bears many shapes, but it leaves the body in two forms alone, as heat and as the work done by the muscles of the frame. All the inner labour of the body, both that of the chemical gland-cells, of the vibrating nerve-substance with its accompanying changes of con-

sciousness, and of the beating heart and writhing visceral muscles, is sooner or later, by friction or otherwise, converted into heat; and it is as heat that the energy evolved in this labour leaves the body. manifold as seems the body's energy, it has but one source, the decay of living material, i.e., the oxidation of complex substances diversely built up into various living matters, and but two ends, heat and muscular work. The continued setting free of energy which thus marks the living body, entailing as it does the continued breaking up and decay of living substance, constitutes a drain upon the body which must be met by constantly-renewed supplies, or otherwise the body would waste away and its energy flicker out. Hence the necessity on the one hand for that which we call food, which, however varied, is essentially a mixture of complex combustible energy-holding bodies, and on the other hand for that other kind of food which we call breath, and which supplies the oxygen whereby the complex oxidizable substances may be oxidized to simpler matters and their potential energy made to do work. Thus food supplies the energy of the body, but in quantity only, not in quality. The food by itself, the dead food, can exhibit energy as heat only, with intervening phases of chemical action; before its energy can be turned into the peculiar grooves of nervous and muscular action it needs to be transmuted into living substance, and in that transmutation there is a preliminary expenditure of part of the food's store of energy.

Here, then, we have a second view of physiological labour. To the conception of the body as an assemblage of molecular thrills—some started by an agent outside the body, by light, heat, sound, touch, or the like: others begun within the body, spontaneously as it were, without external cause: thrills which, travelling to and fro, mingling with and commingling each other, either end in muscular movements or die away within the body—to this conception we must add a chemical one, that of the dead food continually being changed and raised into the living substance, and of the living substance continually breaking down into the waste matters of the body by processes of oxidation, and thus supplying the energy needed both for the unseen molecular thrills and the visible muscular movements.

Here the problems of physiology may in a broad sense be spoken of as threefold. (1) On the one hand, we have to search the laws according to which the complex unstable food is transmuted into the still more complex and still more unstable living flesh, and the laws according to which this living substance breaks down into simple, stable waste products, void or nearly void of energy. (2) On the other hand, we have to determine the laws according to which the vibrations of the nervous substance originate from extrinsic and intrinsic causes, the laws according to which these vibrations pass to and fro in the body acting and reacting upon each other, and the laws according to which they finally break up and are lost, either in those larger swings of muscular contraction whereby the movements of the body are effected, or in some other way. (3) And lastly, we have to attack the abstruser problems of how these neural vibrations, often mysteriously attended with changes of consciousness, as well as the less subtle vibrations of the contracting muscles, are wrought out of the explosive chemical decompositions of the nervous and muscular substances, that is, of how the energy of chemical action is transmuted into and serves as the supply of that vital energy which appears as movement, feeling, and thought.

Even a rough initial analysis, however, such as we have just attempted to sketch, simple as it seems with our present knowledge, is an expression of the accumulated and corrected inquiries of many ages: the ideas which it embodies are the results of long-continued investigations, and the residue of many successive phases of opinion.

Animal  
and vital  
spirits

In the natural hierarchy of the sciences, physiology follows after chemistry, which in turn follows physics, molar and molecular; and in a natural development, as indeed is evident from what we have just seen, the study of the two latter should precede that of the former. At a very early age, however, the exigencies of life brought the study of man, and so of physiology, to the front before its time; hence the history of physiology consists to a large extent, especially in its opening chapters, of premature vain attempts to solve physical and chemical problems before the advent of adequate physical or chemical knowledge. But no ignorance of these matters could hide from the observant mind, even in quite early times, two salient points which appear also in the analysis just given, namely, that, while some of the phenomena of living beings seem due to powers wholly unknown in things which are not living, other phenomena, though at first sight special to living beings, appear to be in reality the peculiar outcome of processes taking place as well in things not alive. It was further early seen that, while the former are much more conspicuous, and make up a greater part of the life of the individual in those living beings which are called animals, especially in man, and in animals more closely resembling man, than in those which are called plants, the latter are common to both divisions of living things. Both sets of phenomena, however, were at first regarded as the products of certain special agencies; both were spoken of as the work of certain spirits; and the distinction between the two was formulated by speaking of the spirits as being in the former case *animal* and in the latter *vital*.

From the very outset even the casual observer could not fail to be struck with the fact that many of the processes of living beings appear to be the results of the various contrivances or machines of which a living body is largely built up. This indeed was evident even before the distinction between animal and vital spirits was recognized; and, when that differentiation was accepted, it was seen that the part played by these machines and contrivances in determining the actions of living beings was much more conspicuous in the domain of vital than of animal spirits. As inquiry was pushed forward the prominence and importance of this machinery became greater and greater, more especially since the phenomena supposed to be due to the agency of vital spirits proved more open to direct observation and experiment than those attributed to the animal spirits. It was found that the most fruitful path of investigation lay in the direction of studying the structure and independent action of the several constituent machines of the body, and of unravelling their mutual relations.

Organs  
and func-  
tions

The machines received the names of organs, the work or action of an organ being at a later period spoken of as its function. And, when it became clear that many of the problems concerned with what was supposed to be the work of the vital spirits could be solved by the proper appreciation of the functions of certain organs, it was inferred that the more difficult problems belonging to the animal spirits could be solved in the same way. Still later on it was found that the conception of organs and functions was not only quite separable from, but indeed antagonistic to, the hypothesis of the entities called spirits.

In this way the first great phase, as it may be called, of the science of physiology was evolved,—a phase which lasted till quite recent times. Under this conception every living being, plant or animal, was regarded as a complex of organs, each with its respective function, as an engine built up of a number of intricately contrived machines, each performing its specific work. The whole animal body was parcelled out into organs, each of which was supposed to have its appropriate function; and the

efforts of investigators were directed, on the one hand, to a careful examination of the structural features of an organ with the view of determining by deduction what its function must be, and, on the other hand, to confirming or correcting by observation and experiment the conclusions thus reached by the anatomical method. And the fruitfulness of this line of inquiry proved so great that the ideas directing it became absolutely dominant. In many cases the problem to be worked out was in reality a purely mechanical one. This was notably so in the great question of the circulation so brilliantly solved by Harvey. Putting aside for a while the inquiry as to the origin of the force with which the walls of the heart press on the blood contained in its cavities, accepting the fact that the blood is thus pressed at each beat of the heart, all the other truths of the circulation which Harvey demonstrated are simply the outcome of certain mechanical conditions, such as the position and arrangement of the valves, the connexion of various patent tubes, and the like. And many other problems—as, for instance, those connected with respiration—proved to be similarly capable of solution by the application of ordinary mechanical principles to anatomical facts.

So fruitful, and consequently so adequate, seemed this conception of living beings as built up of contrivances or organs, in contrast with the lifeless world in whose monotonous masses no such structural disposition could be recognized, that the word "*organic*" came into use as a term distinctive of living things. The phrase was especially adopted by the chemists, who for a long time classified their material into "*organic*" substances, *i.e.*, substances found only in living beings, and into inorganic substances, that is, substances occurring in lifeless bodies as well. Indeed, this nomenclature has not even yet been wholly abandoned. Triumphant, however, as was this mode of inquiry in these and similar instances, there remained in every investigation an unsolvable residue, like the question of the origin of the force exerted by the heart referred to above in speaking of Harvey's work; and in many other instances the questions which could not be solved on mechanical principles formed a great part of the whole problem. Thus in the case of the liver careful dissection showed that minute tubes starting from all parts of the liver joined into one large canal, which opened into the small intestine, and observation and experiment taught that these tubes during life conveyed from the liver to the intestine a peculiar fluid called bile, which appeared on the one hand to originate in the liver, and on the other to be used up for some purposes in the intestine. But here the mere mechanical flow of the bile along the gall-ducts, instead of being of primary, was merely of secondary importance, and the problem of how the bile was generated and made its way into the small beginnings of the ducts was the greater part of the whole matter. This latter problem was left unsolved, and indeed for a while unattempted. Nevertheless the success in other directions attending the conception of organs and functions encouraged physiologists to speak of the liver as an organ whose function was to secrete bile, and further, led them to ignore to a large extent the great unsolved portion of the problem, and to regard the mere enunciation of the function as the chief end of physiological inquiry.

Moreover, whenever attempts were made to unravel these obscure problems, the efforts of investigators were mainly confined to a fuller and more complete elucidation of the supposed function of an organ, and the method of inquiry adopted was in most cases one which regarded the finer elements of the part studied as minute organs making up the whole gross organ, and which sought to explain the functions of these smaller organs on the same mechanical

principles which had proved so successful in the case of the whole organ. When the improvements in the microscope opened up a new world to the anatomist, and a wholly fresh mechanical analysis of the structure of living bodies became possible, great hopes were entertained that the old method applied to the new facts would soon solve the riddles of life by showing how the mysterious operations of the living substances out of which the grosser organs were built were the outcome of structural arrangements which had hitherto remained invisible, were in fact the functions of minute component organs. A vision of a grand simplicity of organic nature dawned upon the minds of physiologists. It seemed possible to conceive of all living beings as composed of minute organic units, of units whose different actions resulted from their different structural characters, whose functions were explicable by, and could be deduced from, their anatomical features, such units being built up into a number of gross organs, the functions of each of which could in turn be explained by the direction which its mechanical build gave to the efforts of its constituent units. Such a view seemed to have touched the goal, when, in the first half of this century, the so-called "cell-theory" was enunciated as a physiological generalization.

Cell-theory. Long before, in the previous century, the genius of Caspar Wolff had led him to maintain that the bodies of living beings may be regarded as composed of minute constituent units, which, being in early life all alike and put together as an unformed mass, gradually differentiate and are ultimately arranged into the tissues and organs of the adult being. But, though Wolff was not unaware of the physiological bearing of his conception, his mind was chiefly bent towards morphological views, and his cell-theory is essentially a morphological one. The cell-theory, however, which became famous in the third decade of the present century, and to which the twin names of Schwann and Schleiden will always be attached, was essentially a physiological one. The chief interest which these authors felt in the ideas that they put forth centred in the conviction that the properties of the cell as they described it were the mechanical outcome of its build; and for a time it seemed possible that all physiological phenomena could be deduced from the functions of cells, the anatomical characters of the various kinds of cells determining in turn their special functions. In the cell-theory the conception of organs and functions reached its zenith; but thenceforward its fall, which had been long prepared, was swift and great. Two movements especially hurried on its decline.

It had long been a reproach to physiologists that, while to most organs of the body an appropriate function had been assigned, in respect to certain even conspicuous organs no special use or definite work could be proved to exist. Of these apparently functionless organs the most notorious instance was that of the spleen, a large and important body, whose structure, though intricate, gave no sign of what its labours were, and whose apparent uselessness was a stumbling-block to the theological speculations of Paley. While in the case of other organs a definite function could be readily enunciated in a few words, and their existence therefore easily accounted for, the spleen remained an opprobrium, existing, as it appeared to do, without purpose, and therefore without cause.

The progress of discovery during the present century, by a cruel blow, instead of pointing out the missing use of the spleen, rudely shook the confidence with which the physiologists concluded that they had solved the riddle of an organ when they had allotted to it a special function. From very old times it had been settled that the function of the liver was to secrete bile; and the only problems

left for inquiry as touching the liver seemed to be those which should show how the minute structure of the organ was adapted for carrying on this work. About the middle of this century, however, the genius of Claude Bernard led him to the discovery that the secretion of bile was by no means the chief labour of the liver. He showed that this great viscus had other work to do than that of secreting bile, had another "function" to perform, but a function which seemed to have no reference whatever to the mechanical arrangements of the organ, which could never have been deduced from any inspection however complete of its structure, even of its most hidden and minute features, and which therefore could not be called a function in the old and proper sense of that word. By a remarkable series of experiments, which might have been carried out by one knowing absolutely nothing of the structural arrangements of the liver beyond the fact that blood flowed to it along the portal vein, and from it along the hepatic vein, he proved that the liver, in addition to the task of secreting bile, was during life engaged in carrying on a chemical transformation by means of which it was able to manufacture and store up in its substance a peculiar kind of starch, to which the name of *glycogen* was given. Bernard himself spoke of this as the glycogenic function of the liver, but he used the word "function" in a broad indefinite sense, simply as work done, and not in the older narrower meaning as work done by an organ structurally adapted to carry on a work which was the inevitable outcome of the form and internal build of the organ. In this glycogenic function organization, save only the arrangements by means of which the blood flows on from the portal to the hepatic channels in close proximity to the minute units of the liver-substance, the so-called hepatic cells, appeared to play no part whatever; it was not a function, and in reference to it the liver was not an organ, in the old senses of the words. This discovery of Bernard's threw a great flash of light into the darkness hitherto hiding the many ties which bound together distant and mechanically isolated parts of the animal body. Obviously the liver made this glycogen, not for itself, but for other parts of the body; it laboured to produce, but they made use of, the precious material, which thus became a bond of union between the two.

The glycogenic labours of the simple hepatic substance carried out independently of all intricate structural arrangements, and existing in addition to the hepatic function of secreting bile, being thus revealed, men began to ask themselves the question, May not something like this be true of other organs to which we have allotted a function and thereupon rested content? And further, in the cases where we have striven in hope, and yet in vain, to complete the interpretation of the function of an organ, by finding in the minute microscopic details of its structure the mechanical arrangements which determine its work, may we not have followed throughout a false lead, and sought for organization where organization in our sense of the word does not exist? The answer to this question, and that an affirmative one, was hastened by the collapse of the cell-theory on its physiological side, very soon after it had been distinctly formulated.

The "cell," according to the views of those who first propounded the cell-theory, consisted essentially of an envelope or "cell-membrane," of a substance or substances contained within the cell-membrane, hence called cell-contents, and of a central body or kernel called the "nucleus," differing in nature from the rest of the cell-contents. And, when facts were rapidly accumulated, all tending to prove that the several parts of the animal or vegetable body, diverse as they were in appearance and structure, were all built up of cells more or less modified,

the hope arose that the functions of the cell might be deduced from the mutual relations of cell-membrane, cell-contents, and nucleus, and that the functions of an organ might be deduced from the modified functions of the constituent modified cells. Continued investigation, however, proved destructive of this physiological cell-theory. It soon became evident that the possession of an investing envelope or cell-membrane was no essential feature of a cell, and that even the central kernel or nucleus might at times be absent. It was seen in fact that the anatomical unit need have no visible parts at all, but might be simply a minute mass, limited in various ways, of the material spoken of as cell-contents. Under the cell-theory, the cell was supposed to be the first step in organization, the step by which a quantity of formless unorganized plasma became an organized unit; this plasma was further supposed still to form the chief part of the cell-contents, and soon became recognized under the name of protoplasm. Hence the destructive anatomical researches which deprived the cell of its cell-membrane, and even of its nucleus, left nothing except a mass of protoplasm to constitute an anatomical unit. For such a unit the word "cell" was a misnomer, since all the ideas of organization denoted by the word had thus vanished; nevertheless it was retained with the new meaning, and up to the present time the definition of a cell is that of a limited mass of protoplasm, generally but not always containing a modified kernel or nucleus.

Proto-  
plasm.

Proto-  
plasmic  
theory.

With this anatomical change of front the physiological cell-theory was utterly destroyed. The cell was no longer a unit of organization; it was merely a limited mass of protoplasm, in which, beyond the presence of a nucleus, there was no visible distinction of parts. It was no longer possible to refer the physiological phenomena of the cell to its organization; it became evident that the work done by a "cell" was the result not of its form and cellular structure but simply of the nature and properties of the apparently structureless protoplasm which formed its body. A new idea pressed itself on men's minds, that organization was a concomitant and result of vital action, not its condition and cause; as Huxley in one of his earliest writings put it, "They [cells] are no more the producers of the vital phenomena than the shells scattered in orderly lines along the sea-beach are the instruments by which the gravitative force of the moon acts upon the ocean. Like these, the cells mark only where the vital tides have been, and how they have acted."<sup>1</sup> Hence arose the second of the two movements mentioned above, that which may be called the "protoplasmic" movement, a movement which, throwing overboard altogether all conceptions of life as the outcome of organization, as the mechanical result of structural conditions, attempts to put physiology on the same footing as physics and chemistry, and regards all vital phenomena as the complex products of certain fundamental properties exhibited by matter, which, either from its intrinsic nature or from its existing in peculiar conditions, is known as living matter, —mechanical contrivances in the form of organs serving only to modify in special ways the results of the exercise of these fundamental activities and in no sense determining their initial development.

tissues.

Long before the cell-theory had reduced to an absurdity the "organic" conception of physiology, the insight of the brilliant Bichat, so early lost to science, had led him to prepare the way for modern views by developing his doctrine of "tissues." That doctrine regarded the body as made up of a number of different kinds of living material, each kind of material having certain innate qualities proper to itself

<sup>1</sup> "The Cell-Theory," in *Brit. and For. Med. Chir. Rev.*, vol. xii. (1853) p. 314.

as well as certain structural features, and the several kinds of material being variously arranged in the body. Each of these body-components was spoken of as a tissue, muscular tissue, nervous tissue, and the like; and the varied actions of the body were regarded as the result of the activities of the several tissues modified and directed by the circumstance that the tissues were to a great extent arranged in mechanical contrivances or organs which largely determined the character and scope of their actions.

The imperfection of microscopic methods in Bichat's time, and, we may perhaps add, his early death, prevented him from carrying out an adequate analysis of the qualities or properties of the tissues themselves. During the middle portion of this century, however, histological investigation, i.e., inquiry into the minute structure of the tissues, made enormous progress, and laid the basis for a physiological analysis of the properties of tissues. In a short time it became possible to lay down the generalization that all the several tissues arise, as far as structure is concerned, by a differentiation of a simple primitive living matter, and that the respective properties of each tissue are nothing more than certain of the fundamental properties of the primordial substance thrown into prominence by a division of labour running to a certain extent parallel to the differentiation of structure. Developed in a fuller manner, this modern doctrine may be expounded somewhat as follows.

In its simplest form, a living being, as illustrated by Evolution, some of the forms often spoken of as amoebae, consists of a mass of substance in which there is no obvious distinction of parts. In the body of such a creature even the highest available powers of the microscope reveal nothing more than a fairly uniform network of material, a network sometimes compressed, with narrow meshes, sometimes more open, with wider meshes, the intervals of the mesh-work being filled, now with a fluid, now with a more solid substance or with a finer and more delicate network, and minute particles or granules of variable size being sometimes lodged in the open meshes, sometimes deposited in the strands of the network. Sometimes, however, the network is so close, or the meshes filled up with material so identical in refractive power with the bars or films of the network, and at the same time so free from granules, that the whole substance appears absolutely homogeneous, glassy or hyaline. Analysis with various staining and other reagents leads to the conclusion that the substance of the network is of a different character from the substance filling up the meshes. Similar analysis shows that at times the bars or films of the network are not homogeneous, but composed of different kinds of stuff; yet even in these cases it is difficult if not impossible to recognize any definite relation of the components to each other such as might deserve the name of structure; and certainly in what may be taken as the more typical instance, where the network seems homogeneous, no microscopic search is able to reveal to us a distinct structural arrangement in its substance. In all probability optical analysis, with all its aids, has here nearly reached its limits; and, though not wholly justified, we may perhaps claim the right to conclude that the network in such case is made up of a visible, though it may vary in places or at times in what may be spoken of as molecular construction, and may carry, lodged in its own substance, a variety of matters foreign to its real self. This remarkable network is often spoken of as consisting of protoplasm, and, though that word has come to be used in several different meanings, we may for the present retain the term. The body of an amoeba, then, or of a similar organism consists of a network or framework which we may speak of as protoplasm, filled up with other matters. In most cases it is true that in

tion and  
characteristics  
of protoplasm.

the midst of this protoplasmic body there is seen a peculiar body of a somewhat different and yet allied nature, the so-called nucleus; but this we have reason to think is specially concerned with processes of division or reproduction, and may be absent, for a time at all events, without any injury to the general properties of the protoplasmic body.

Now such a body, such a mass of simple protoplasm, homogeneous save for the admixtures spoken of above, is a living body, and all the phenomena which we sketched out at the very beginning of this article as characteristic of the living being may be recognized in it. There is the same continued chemical transformation, the same rise and fall in chemical dignity, the same rise of the dead food into the more complex living substance, the same fall of the living substance into simpler waste-products. There is the same power of active movement, a movement of one part of the body upon another giving rise to a change of form, and a series of changes of form resulting eventually in a change of place. In what may be called the condition of rest the body assumes a more or less spherical shape. By the active transference of part of the mass in this or that direction the sphere flattens itself into a disk, or takes on the shape of a pear, or of a rounded triangle, or assumes a wholly irregular, often star-shaped or branched form. Each of these transformations is simply a rearrangement of the mass, without change of bulk. When a bulging of one part of the body takes place there is an equivalent retraction of some other part or parts; and it not unfrequently happens that one part of the body is repeatedly thrust forward, bulging succeeding bulging, and each bulging accompanied by a corresponding retraction of the opposite side, so that, by a series of movements, the whole body is shifted along the line of the protuberances. The tiny mass of simple living matter moves onward, and that with some rapidity, by what appears to be a repeated flux of its semi-liquid substance.

The internal changes leading to these movements may begin, and the movements themselves be executed, by any part of the uniform body; and they may take place without any obvious cause. So far from being always the mere passive results of the action of extrinsic forces, they may occur spontaneously, that is, without the coincidence of any recognizable disturbance whatever in the external conditions to which the body is exposed. They appear to be analogous to what in higher animals we speak of as acts of volition. They may, however, be provoked by changes in the external conditions. A quiescent amoeba may be excited to activity by the touch of some strange body, or by some other event,—by what in the ordinary language of physiology is spoken of as a stimulus. The protoplasmic mass is not only mobile but sensitive. When a stimulus is applied to one part of the surface a movement may commence in another and quite distant part of the body; that is to say, molecular disturbances appear to be propagated along its substance without visible change, after the fashion of the nervous impulses we spoke of in the beginning of this article. The uniform protoplasmic mass of the amoeba exhibits the rudiments of those attributes or powers which in the initial sketch we described as being the fundamental characteristics of the muscular and nervous structures of the higher animals.

These facts, and other considerations which might be brought forward, lead to the tentative conception of protoplasm as being a substance (if we may use that word in a somewhat loose sense) not only unstable in nature but subject to incessant change, existing indeed as the expression of incessant molecular, that is, chemical and physical change, very much as a fountain is the expression of an incessant replacement of water. We may picture to

ourselves this total change which we denote by the term "metabolism" as consisting on the one hand of a downward series of changes (*katabolic* changes), a stair of many steps, in which more complex bodies are broken down with the setting free of energy into simpler and simpler waste bodies, and on the other hand of an upward series of changes (*anabolic* changes), also a stair of many steps, by which the dead food, of varying simplicity or complexity, is, with the further assumption of energy, built up into more and more complex bodies. The summit of this double stair we call "protoplasm." Whether we have a right to speak of it as a single body, in the chemical sense of that word, or as a mixture in some way of several bodies, whether we should regard it as the very summit of the double stair, or as embracing as well the topmost steps on either side, we cannot at present tell. Even if there be a single substance forming the summit, its existence is absolutely temporary: at one instant it is made, at the next it is unmade. Matter which is passing through the phase of life rolls up the ascending steps to the top, and forthwith rolls down on the other side. But to this point we shall return later on. Further, the dead food, itself fairly but far from wholly stable in character, becomes more and more unstable as it rises into the more complex living material. It becomes more and more explosive, and when it reaches the summit its equilibrium is overthrown and it actually explodes. The whole downward stair of events seems in fact to be a series of explosions, by means of which the energy latent in the dead food and augmented by the touches through which the dead food becomes living protoplasm, is set free. Some of this freed energy is used up again within the material itself, in order to carry on this same vivification of dead food; the rest leaves the body as heat or motion. Sometimes the explosions are, so to speak, scattered, going off as it were irregularly throughout the material, like a quantity of gunpowder sprinkled over a surface, giving rise to innumerable minute puffs, but producing no massive visible effects. Sometimes they take place in unison, many occurring together, or in such rapid sequence that a summation of their effects is possible, as in gunpowder rammed into a charge, and we are then able to recognize their result as visible movement, or as appreciable rise of temperature.

These various phenomena of protoplasm may be conveniently spoken of under the designation of so many properties, or attributes, or powers of protoplasm, it being understood that these words are used in a general and not in any definite scholastic sense. Thus we may speak of protoplasm as having the power of *assimilation*, i.e., of building up the dead food into its living self; of movement, or of *contractility* as it is called, i.e., of changing its form through internal explosive changes; and of *irritability* or *sensitiveness*, i.e., of responding to external changes, by less massive internal explosions which, spreading through its mass, are not in themselves recognizable through visible changes, though they may initiate the larger visible changes of movement.

These and other fundamental characters, all associated with the double upward and downward series of chemical changes, of constructive and destructive metabolism, are present in protoplasm wherever found; but a very brief survey soon teaches us that specimens of protoplasm existing in different beings or in different parts of the same being differ widely in the relative prominence of one or another of these fundamental characters. On the one hand, in one specimen of protoplasm the energy which is set free by the series of explosions constituting the downward changes of destructive metabolism may be so directed as to leave the mass almost wholly in the form of heat, thus producing very little visible massive change of form. Such a protoplasm consequently, however irritable and

plasm.

explosive, exhibits little power of contractility or movement. In another specimen, on the other hand, a very large portion of the energy similarly set free may be spent in producing visible changes of form, the protoplasm in this instance being exquisitely mobile. Such differences must be due to different internal arrangements of the protoplasm, though, since no vision, however well assisted, can detect these arrangements, they must be of a molecular nature rather than of that grosser kind which we generally speak of as structural. It is true that, as the differences in properties become more and more prominent, as the protoplasm becomes more and more specialized, features which we can recognize as structural intervene; but even these appear to be subsidiary, to accompany and to be the result of the differences in property, or to be concerned in giving special directions to the activities developed, and not to be the real cause of the differences in action. We are thus led to the conception of protoplasm as existing in various differentiated conditions while still retaining its general protoplasmic nature, a difference of constitution making itself felt in the different character of the work done, in a variation of the results of the protoplasmic life. We have a division of physiological labour going hand in hand with a differentiation of material, accompanied ultimately by morphological results which may fairly be spoken of as constituting a differentiation of structure.

Some of the simpler and earlier features of such a division and differentiation may be brought out by comparing with the life of such a being as the *amœba* that of a more complex and yet simple organism as the *hydra* or freshwater polyp. Leaving out certain details of structure, which need not concern us now, we may say that the *hydra* consists of a large number of units or cells firmly attached to each other, each cell being composed of protoplasm, and in its broad features resembling an *amœba*. The polyp is in fact a group or crowd of *amœba*-like cells so associated together that, not only may the material of each cell, within limits, be interchanged with that of neighbouring cells, but also the dynamic events taking place in one cell, and leading to exhibitions of energy, may be similarly communicated to neighbouring cells, also within limits. These cells are arranged in a particular way to form the walls of a tube, of which the body of the *hydra* practically consists. They form two layers in apposition, one an internal layer called the *endoderm*, lining the tube, the other an external layer called the *ectoderm*, forming the outside of the tube. And, putting aside minor details, the differences in structure and function observable in the organism are confined to differences between the *ectoderm* on the one hand, all the constituent cells of which are practically alike, and the *endoderm* on the other, all the cells of which are in turn similarly alike. The protoplasm of the *ectoderm* cells is so constituted as to exhibit in a marked degree the phenomena of which we spoke above as irritability and contractility, whereas in the *endoderm* these phenomena are in abeyance, those of assimilation being prominent. The movements of the *hydra* are chiefly brought about by changes of form of the *ectoderm* cells, especially of tail-like processes of these cells, which, arranged as a longitudinal wrapping of the tubular body, draw it together when they shorten, and lengthen it out when they elongate, and it is by the alternate lengthening and shortening of its body, and of the several parts of its body, that the *hydra* changes its form and moves from place to place. Inaugurating these changes of form, the products of contractility, are the more hidden changes of irritability; these also are especially developed in the *ectoderm* cells, and travel readily from cell to cell, so that a disturbance originating in one cell, either from some extrinsic cause, such as contact with a

foreign body, or from intrinsic events, may sweep from cell to cell over the surface of the whole body. The animal feels as well as moves by means of its *ectoderm* cells. In the *endoderm* cells the above phenomena, though not wholly absent, are far less striking, for these cells are almost wholly taken up in the chemical work of digesting and assimilating the food received into the cavity, the lining of which they form.

Thus the total labour of the organism is divided between these two membranes. The *endoderm* cells receive food, transmute it, and prepare it in such a way that it only needs a few final touches to become living material, these same cells getting rid at the same time of useless ingredients and waste matter. Of the food thus prepared the *endoderm* cells, however, themselves use but little; the waste of substance involved in the explosions which carry out movement and feeling is reduced in them to a minimum; they are able to pass on the greater part of the elaborated nourishment to their brethren the *ectoderm* cells. And these, thus amply supplied with material which it needs but little expenditure of energy on their part to convert into their living selves, thus relieved of the greater part of nutritive labour, are able to devote nearly the whole of their energies to movement and to feeling.

Microscopic examination further shows that these two kinds of cells differ from each other to some extent in visible characters; and, though, as we have seen, the differences in activity appear to be dependent on differences in invisible molecular arrangement rather than on gross visible differences such as may be called structural, still the invisible differences involve or entail, or are accompanied by, visible differences, and such differences as can be recognized between *endoderm* and *ectoderm*, even with our present knowledge, may be correlated to differences in their work; future inquiry will probably render the correlation still more distinct.

The *ectoderm* cells together constitute what we have spoken of above as a tissue, whose function in the modern sense of the word is movement and feeling, and the *endoderm* cells constitute a second tissue, whose function is assimilation; and the phenomena of the whole being result from the concurrent working of these two functions. Of organs, in the old sense of the word, of mechanical contrivances, there is hardly a trace.<sup>1</sup> The performances of the being are, it is true, conditioned by its being moulded in the form of a long tubular sac with a crown of like tubular arms, but beyond this the explanation of every act of the *hydra*'s life is first to be sought in the characters of the *endoderm* and *ectoderm*. The physiology of the *hydra* is, for the most part, a series of problems, dealing on the one hand with the intimate nature of the *ectodermic* protoplasm and the changes in that protoplasm which give rise to movement and feeling, as well as with the laws whereby those changes are so regulated that movement and feeling come and go as the needs of the organism may require, and on the other hand with the intimate nature of the *endodermic* protoplasm and the changes in that protoplasm whereby the dead food is, also according to the needs of the economy, transformed into living substance. Whereas the older physiology dealt almost exclusively with mechanical problems, the physiology of to-day is chiefly busied with what may be called molecular problems.

The physiology of the higher animals, including man, is merely a development of the simpler physiology of the *hydra*, which has been rendered more complex by a greater division of physiological labour, entailing greater differen-

<sup>1</sup> The existence of certain minute mechanisms called urticating organs lodged in the *ectoderm* cells does not affect the present argument.

tiation of structure, and been varied by the intercalation of numerous mechanical contrivances.

Diff. in  
exten-  
sion of  
ecto-  
derm.

In the hydra each ectoderm cell—for, broadly speaking, they are all alike—serve three chief purposes of the body. (1) It is sensitive, that is, it is thrown into peculiar molecular agitations, with expenditure of energy, when acted upon by external agents. In man and the higher animals certain cells of the original ectoderm of the embryo are differentiated from their fellows (which, losing to a large extent this sensitiveness, remain as a mechanical covering to the body) by a more exquisite development of this power of reaction, and moreover are differentiated from each other in their relative sensitiveness to different agents, so that one set of cells becomes peculiarly susceptible to light, another set to pressure, and the like. Thus the uniform ectoderm of the hydra, uniformly susceptible to all agencies, is replaced by a series of special groups of cells forming the basis of sensory organs, each group being specially sensitive to one agent, and having the nature of its constituent cells correspondingly modified. (2) In each ectoderm cell of the hydra the agitations primarily induced by the exciting agent become so modified by changes taking place in the cell that the outcome is not always the same. According to processes taking place in the cell, movement of one kind or another, or no movement at all, may result, and such movement as results may take place immediately or at some other time; it may be at a time so distant that the connection between the exciting disturbance is lost, and the movement appears to be spontaneous. In man and the higher animals these more complex "neural" processes are carried on, not by the simple sensory cells which receive the primary impression, but by a group of cells set apart for the purpose. These cells constitute a central nervous system, in which a still further division of labour and differentiation of structure takes place, the simple neurotic processes of the hydra, with its diminution and limited scope of action, being developed in a complex manner into processes which range from simple elaboration of the initial additional agitation of the sensory cell into what we speak of as intelligence and thought. (3) Each ectoderm cell, by its tail-like prolongation, or by its whole body, contributes to the movement of the animal while still carrying on the two other actions just described. In man and the higher animals the material of the sensory cell and of the central nervous cells is too precious to be wasted in movements; these accordingly are carried out by groups of cells constituting the muscular tissue, in which both the sensitiveness and the higher neurotic processes of the primitive cell are held in abeyance; indeed, the latter have almost disappeared in order that the energy of the protoplasm may be more completely directed to producing those changes of form which determine the movements of the animal.

Further, the separation in space of these three groups of cells or tissues necessitates the introduction of elements whereby the agitations set up in the sensory cell should be communicated to the central nervous cell, where these agitations are further elaborated, as well as of elements whereby the muscular tissue may receive vibrations from the central nervous cells, so that the movements of the body may be determined by these. Hence strands of irritable protoplasm whose energy is not spent in movement, but wholly given up to the rapid and easy transmission of molecular vibrations, unite, as sensory nerves, the sensory cells with the central nervous cell, and, as motor nerves, these with the muscles.

Lastly, for the adequate carrying out of complex movements, the contractile cells, elongated into specially constructed fibres and constituting the muscles, are arranged, with inert tissues such as bones, cartilages, tendons, and

the like (tissues of mechanical virtue, manufactured by an active protoplasm, but themselves passive, no longer active), into various mechanical contrivances. Similarly the sensory cells, as notably those of the eye and the ear, set apart to be acted upon by special agents, are provided with special mechanisms in order that the agent may act with more complete precision. Thus the sensory cells constituting the retina of the eye, in which alone sensory, visual impulses are generated, are provided with an intricate dioptric mechanism, formed partly of inert tissues such as the lens, partly of peculiarly arranged muscular and nervous elements.

In this way the simple ectoderm of the hydra is replaced by a complicated system composed of organs, some of them of extreme intricacy. But the whole system may be reduced to two sets of factors. On the one hand there are organs in the old sense of the word, that is, mechanical arrangements, some connected with the muscles, and others connected with the sensory cells, organs whose functions have for the most part to be interpreted on mechanical principles, since their most important factors, putting aside intervening muscular and nervous elements, are the inert products of protoplasm doing simple mechanical work. On the other hand there are organs in the later sense of the word, namely, sensory cells differentiated to be sensitive to special influences, central nervous cells differentiated to carry on the inner nervous work, muscles differentiated to contract, and nerves differentiated to bind together these three other factors. The work of these latter organs is dependent on the nature of their protoplasm: mechanical arrangements play but little part in them; and the results of their activity can in no way be explained on simple mechanical principles.

Corresponding with this differentiation of the ectoderm cells runs a somewhat similar differentiation of the endoderm cells. In the hydra each endoderm cell appears to receive some of the food bodily into itself and there to elaborate it into what may be spoken of as prepared nutritive material. Some of this material the cell retains within itself in order to renew its own protoplasm: the rest oozes out to the ectoderm cells, the replenishment of whose protoplasm is thereby effected with a saving of labour. In the higher animals the preparation of food is far more complicated. The endodermic sheet of the alimentary canal is folded and arranged into organs called glands, with the mechanical advantage that a large amount of surface is secured within a small bulk; and the constituent endodermic cells of their glands pour out, or secrete, as is said, divers fluids into the cavity of the canal, so that much preliminary preparation of digestion of the food takes place before the food really enters the body. Further, these secreting glandular cells are so differentiated as to pour out special juices acting on special constituents of a meal, and the food subjected in turn to the action of these several juices becomes thoroughly prepared for reception into the body. This reception is carried out by other endoderm cells, which in receiving the digested food probably act upon it so as still further to heighten its nutritive value; and the absorbed food, before it is presented to the muscular and nervous tissues, for whose use it is largely, though of course not exclusively, intended, is subjected to the action of other cells, such as those forming the lymphatic glands and the liver, in order that it may be still further elaborated, still further prepared for the final conversion into living protoplasm.

As in the case of the tissues and organs of ectodermic origin, so also here, the wide separation in space of the masses of differentiated cells constituting tissues necessitates the introduction of mechanical contrivances for the carriage of material from place to place. In the simple

**Vascular system.** minute hydra the nutritive material can permeate the whole body by simply oozing from cell to cell. In the higher animal a hydraulic system for the distribution of nutritive material is introduced. A fluid is distributed in a ceaseless flow all over the body by a mechanical arrangement, consisting of a pump with branching tubes, worked on mechanical principles, and capable of being imitated artificially, save that the power which drives the machine is the energy set free by living muscle. As this circulating fluid or blood rushes past the endoderm cells which have gorged themselves from the rich contents of the alimentary canal, it receives from them some of the material which they have absorbed and elaborated, and carries this nutritive supply to muscles, nerves, and all parts of the body. Similarly it carries away from muscles, nerves, and other tissues the waste-products of their activity, those broken fragments of simpler stuffs into which, as we have seen, the complex protoplasm, wherever it exists, is for ever splitting up, and bears them back to differentiated endoderm and other cells, whose work has become, so to speak, inverted, since their activity is directed to casting things out of the body, instead of receiving things into the body. And lastly, by a special arrangement, by a peculiar property of those red corpuscles which make blood red, this circulating material at one and the same time carries to each corner of the body, not only the nutritive material required for building up protoplasm, but also the oxygen by which the constructed protoplasm may suffer oxidation, and in being oxidized set free that energy the manifestation of which is the token of life. Blood is in fact the medium on which all the various parts of the body live. Just as an amoeba finds in the water which is its home both the food with which it builds itself up and the oxygen with which it breaks itself down, and returns to the water the waste-products of its continued disintegration, so each islet of the living substance of the higher animal, be it muscle or nerve or gland, draws its food and its oxygen from the red blood-stream sweeping past it, finding therein all its needs, and sheds into the same stream the particles into which it is continually breaking up, and for which it has no longer any use. Hence the blood becomes, as it were, a chemical epitome of the body: from it each tissue takes something away; to it each tissue gives something back. As it sweeps by each tissue, losing and gaining, it makes the whole body common, and when working aright brings it about that each tissue is never in lack of the things which it wants, never choked up with the things with which it has done.

This vascular system, consisting of a force-pump and branching tubes, constitutes, as we have said, a mechanical arrangement worked on mechanical principles. Nevertheless occult protoplasmic processes intervene as factors in its total work. Not only is the force-pump itself a living muscular organ, not only are the walls of the tubes of the system modified by changes not of mechanical origin taking place in them, but the living material which lines the tubing throughout, especially in the minuter channels, finds work to do, also not of a mechanical nature. The gross phenomena of the flow of blood through the capillary channels may (see **VASCULAR SYSTEM**) be interpreted on simple hydraulic principles; but no appeal to the ordinary physical laws of dead material will explain the phenomena of the interchange between the blood on the inside of a capillary wall and the tissue-elements on the outside. In every tissue, be it gland, muscle, or nerve, the blood, so far from being actually in contact with the active protoplasmic units of the tissue, is separated by the protoplasmic film of the capillary wall, and by a space or space, greater or smaller, filled with the fluid called lymph

and lined to a greater or less extent with protoplasmic cells, which lining, often at least, parts the tissue-units from the lymph. Hence the tissue lives upon the lymph, while the lymph is replenished from the blood; and the interchange between the tissue-unit and the blood is determined, not only by the direct action of the tissue-unit on the lymph, but also by the relations of the lymph to the blood, as regulated by the capillary wall and the cellular lining of the lymph-spaces. We may speak of the interchange as broadly one of diffusion or osmosis through filmy membranes; but diffusion is not the lord in the matter: it is rather a humble servant directed hither and thither by occult molecular processes in the protoplasmic structures concerned.

The foregoing rough analysis leads to a conception of the physiology of the animal body which may be expressed somewhat as follows. The body is composed of different kinds of matter; each kind of matter, arranged in units more or less discrete, constitutes a tissue; and the several tissues, though having a common likeness in token of their origin from a common primordial protoplasm, have dissimilar molecular constitutions, entailing dissimilar modes of activity. Nor is each tissue homogeneous, for two parts of the body, though so far alike as to be both examples of the same general tissue, may be different in molecular constitution, more or less distinctly expressed by microscopic differences of structure, and correspondingly different in action. Thus a liver-cell and a kidney-cell, though both examples of glandular tissue, are quite distinct; so also several varieties of muscular tissue exist; and in the dominant nervous tissue we have not only a broad distinction between nerve-fibres and nerve-cells, but the several groups of nerve-cells which are built up into the brain and spinal cord, and indeed probably the single nerve-cells of these, though all possessing the general characters, both in structure and function, of nervous protoplasm, differ most widely from each other. These several tissues of diverse constitution and activity, ranging as regards the rapidity of the molecular changes taking place in them from the irritable, unstable, swiftly-changing nerve-cell to the stable, slowly-changing, almost lifeless tendon or bone, are disposed in the body in various mechanical arrangements constituting organs or machines, whereby the activities of the constituent tissue-elements are brought to bear in special directions. These organs range from those in which the mechanical provisions are dominant, the special activity of the tissue-elements themselves being in the background, and supplying only an obscure or even unimportant factor, as in the organs of respiration, to those in which the mechanical provisions are insignificant, as in the central nervous system, where the chief mechanical factor is supplied by the distribution in space of the nerve fibres or cells.

Hence it is obvious that almost every physiological inquiry of any large scope is, or sooner or later becomes, physiological of a mixed nature. On the one hand, investigation has to be directed to the processes taking place in the actual tissue-elements, in the protoplasmic cells and modifications of cells. These are essentially of a molecular, often of a chemical or chemico-physical nature; in the problems thus raised matters of form and structure, other than that of molecular structure, which no microscope can ever reveal, are of secondary moment only, or have no concern in the matter at all. These may be spoken of as the purely physiological or as the molecular problems. On the other hand, the natural results of these tissue-activities are continually being modified by circumstances whose effect can be traced to the mechanical arrangements under which the tissue in question is acting, whence arise problems which have to be settled on simple mechanical principles. We may take as an illustration the physiology of the

kidney. In the old language the function of the kidney is to secrete urine. When we come to inquire into the matter, we find, in the first place, that the secretion of urine—that is, the quantity and quality of the urine escaping from the duct of the kidney in a given period—is partly determined by the quantity of blood passing through the kidney and the circumstances of its passage. Now the quantity of blood reaching the kidney at any one time is dependent partly on the width of the renal arteries, partly on the general pressure of the blood in the arterial system. The width of the renal arteries is in turn dependent on the condition of their muscular walls, whether contracted or relaxed; and this condition is determined by the advent of nervous impulses, the so-called vaso-motor impulses, arising in the central nervous system and passing down to the renal arteries along certain nerves. The emission of these vaso-motor impulses from the central nervous system is further determined, on the one hand by the condition of certain parts of the central nervous system, the so-called vaso-motor centres, and on the other by the passage of certain afferent sensory impulses to those vaso-motor centres from sensory surfaces such as the skin. Similarly the general blood-pressure is dependent on the condition, patent or narrowed, of the small arteries generally, this being likewise governed by the vaso-motor system and on the coincident work done by the heart in driving blood into the great blood-vessels, this work being also governed by the nervous system. Hence in attacking such a problem as to how any particular event, such as the exposure of skin to the cold, influences the flow of blood through the kidney and thus the secretion of urine, the investigator, without staying to inquire into the nature of nervous impulses, or into the nature of changes taking place in vaso-motor centres, &c., directs his attention to determining what impulses are generated under the circumstances, what paths they take, to what extent they are quantitatively modified, how far they and their effects react upon each other, and so on. His inquiry in fact takes on to a large extent the characters of an attempt to unravel an intricate game, in which the counters are nervous impulses, muscular contractions, and elastic reactions, but in which the moves are determined by topographical distribution and mechanical arrangements.

But there are other problems connected with the physiology of the kidney of quite a different nature. The kidney is, broadly speaking, constructed of living protoplasmic cells so arranged that each cell is on one side bathed with blood and lymph, and on the other forms the boundary of a narrow canal, which, joining with other canals, ultimately opens into the urinary bladder. Here the question arises how it is that these protoplasmic cells, having nothing to draw upon but the common blood, which is distributed to other organs and tissues as well, are able to discharge on the other side of them into the canal the fluid urine, which is absolutely distinct from blood, which contains substances wholly unknown in blood, as well as substances which, though occurring in blood, are found there in minute quantities only, and, moreover, are not found to escape from the blood into any other tissues or organs. In attempting to answer this question we come upon an inquiry of quite a different nature from the preceding, an inquiry for the solution of which mechanical suggestions are useless. We have to deal here with the molecular actions of the protoplasmic cell. We must seek for molecular explanations of the questions, why a current sets across the cells from blood-capillary and lymph-space to the hollow canal; why the substances which emerge on the far side are so wholly unlike those which enter in on the near side; why, moreover, the intensity of this current may wax and wane, now flooding the canal with urine, now nearly or quite drying up; why

not only the intensity of the current but also the absolute and relative amount of the chemical substances carried along it are determined by events taking place in the cell itself, being largely independent of both the quantity and quality of the blood which forms the cell's only source of supply. These and other like questions can only be solved by looking with the mind's eye, by penetrating through careful inferences, into those inner changes which we call molecular, and which no optical aid will ever reveal to the physical eye.

These two lines of inquiry, which we may call the mechanical and the molecular, obtain in all parts of physiology, sometimes the one and sometimes the other being dominant. A study of the special articles dealing with the several parts of physiology (see "Nervous System" below, NUTRITION, REPRODUCTION, RESPIRATION, VASCULAR SYSTEM) will perhaps sufficiently show this; but it may be worth while to give a very brief survey of the whole field from this point of view.

The master tissues and organs of the body are the nervous and muscular systems, the latter being, however, merely the instrument to give effect and expression to the motions of the former. All the rest of the body serves simply either in the way of mechanical aids and protection to the several parts of the muscular and nervous systems, or as a complicated machinery to supply these systems with food and oxygen, *i.e.*, with blood, and to keep them cleansed from waste matters throughout all their varied changes. The physiology of the muscular system is fairly simple. The mechanical problems involved have been long ago for the most part worked out, and the molecular problems which touch on the nature of muscular contractions, their dependence on the blood-supply, and their relations to nervous impulses are being rapidly solved. The physiology of the nervous system, on the other hand, is in its infancy. The mechanical side of the inquiry is here represented, inasmuch as the various actions of the system are conditioned by the distribution and topographical arrangement of the constituent fibres and cells; and even these simple problems, as may be seen from the article "Nervous System" below, are as yet largely unworked. The deeper molecular problems, those which deal with the real nature of the processes taking place in cell and fibre, even the simpler of these, such as the one which asks why the neural protoplasm of one cell, or group of cells, seems quiescent until stirred by some foreign impulse, its own vibrations being otherwise retained and lost within its own substance, while the neural protoplasm of another cell is continually, or from time to time, discharging vibrations, as rhythmic molecular pulses, along adjoining fibres,—these, at the present day, can hardly be said to be touched. The physiology of the nervous system is emphatically the physiology of the future.

The rest of the body may, from a broad point of view, be regarded as a complex machinery for supplying these master tissues with adequately-prepared food and oxygen, for cleansing them from the waste-products of their activity, and for keeping them at a temperature suitable for the development of their powers. As we have already said, the blood is the agent which not only supplies both food and oxygen but sweeps away all refuse, and, we may add, is the instrument for maintaining an adequate temperature. All the rest of the body may in fact be looked upon as busied in manufacturing food into blood, in keeping up the oxygen supply of the blood, in sifting out from the blood all waste material, and in maintaining the blood at a uniform heat. This work, of which blood is, so to speak, the centre, is, as we have already seen, carried out by protoplasmic cells, many of which are themselves of a muscular nature, often forming part of complicated mechanical

contrivances, built up partly of inert tissues, partly of active tissues, such as muscle and nerve. In tracing the food and oxygen into the blood and the waste matters out of the blood, in studying the distribution of the blood itself and the means adopted to maintain its even temperature, we come, as before, on problems partly mechanical or chemical and partly molecular. The changes which the food undergoes in the intestine can be, and have been, successfully studied as a series of purely chemical problems conditioned by anatomical arrangements, such as the existence of an acid fluid in the stomach, succeeded by alkaline fluids in the intestine, and the like; but the questions concerned in the discharge of the digestive juices into the alimentary canal, in the secretory activity of the digestive glands, raise up protoplasmic molecular inquiries. In the reception or absorption of the digested food we similarly find the purely physical processes of diffusion and the like overridden by the special protoplasmic activities of the constituent cells of the lining of the canal. In the further elaboration of the digested products the action of cells again intervenes, as it similarly does in the, so to speak, inverted action by which waste matters are cast out of the body, though in both cases the results are in part conditioned by mechanical contrivances. The circulation of the blood is carried on by means of an intricate mechanical contrivance, whose working is determined and whose effects are conditioned by molecular changes occurring in the constituent muscles and other protoplasmic cells; the work done by the heart, the varying width of the channels, the transit of material through the filmy capillary walls, all these are at once the results of protoplasmic activity and factors in the mechanical problems of the flow of blood. The oxygen passes into and carbonic acid out of the blood, through simple diffusion, by means of the respiratory pump, which is merely a machine whose motive-power is supplied by muscular energy, and both oxygen and carbonic acid are carried along in the blood by simple chemical means; but the passage of oxygen from the blood into the tissue and of carbonic acid from the tissue into the blood, though in themselves mere diffusion processes, are determined by the molecular activity of the constituent cells of the tissue. Lastly, the blood, however

composed of a number of similar units, the unit being a secreting cell of approximately spheroidal form, one part of the surface of which borders a canal continuous with the duct of the gland, while another part is bathed in lymph. The process of secretion consists in the cell discharging into the canal a fluid which is of a specific character, inasmuch as, though it consists partly of water and other substances common to it and other fluids of the body, these are present in it in special proportions; and it also contains substances or a substance found in itself and nowhere else. To enable it to carry on this work the cell receives supplies of material from the lymph in which it is bathed, the lymph in turn being replenished from neighbouring capillary blood-vessels. The secreting cell itself consists of a soft protoplasmic "body," of the nature previously described, in the midst of which lies a "nucleus." The consideration of the actions carried out by the nucleus may, for simplicity's sake, be left on one side for the present; and we may regard the cell as a mass of protoplasm consisting, as we have seen, of a network of a particular nature, and of other substances of different nature filling up the meshes or interstices of the network.

Such a cell may exist under two different conditions. At one time it may be quiescent: although the blood-vessels surrounding it are bathing it with lymph, although this lymph has free access to the protoplasm of the cell, no secretion takes place, no fluid whatever passes from the cell into the canal which it borders. At another time, under, for instance, some influence reaching it along the nerve distributed to the gland, although there may be no change in the quantity or quality of the blood passing through the adjacent blood-vessels, a rapid stream of material flows from the protoplasmic cell-body into the canal. How is this secretion brought about?

If we examine certain cells, such, for instance, as those of the pancreas, we find that during a period of rest succeeding one of activity the cell increases in bulk, and further that the increase is not so much an enlargement of the protoplasmic network as an accumulation of material in the meshes of the network; in fact, there appears to be a relative diminution of the actual protoplasm, indicating, as we shall see, a conversion of the substance of the network into the material which is lodged in the interstices of the network. This material may, and frequently does, exist in the form of discrete granules, recognizable under the microscope; and in the pancreas there is a tendency for these granules to be massed together on the side of the cell bordering the lumen of the canal. During activity, while the cell is discharging its secretion into the canal, these granules disappear, so that the protoplasmic network is after prolonged activity left with a very small burden of material in its meshes; at the same time there also appears to be an accompanying absolute increase of growth of the mass of the protoplasm itself. We have further evidence that the substance which is thus stored up in the meshes of the cell, forming the granules, for instance, just spoken of, is not, as it exists in the cells, the same substance as that which occurs in the secretion as its characteristic constituent. Thus the characteristic constituent of pancreatic juice is a peculiar ferment body called "trypsin," and we possess evidence that the granules in the pancreatic cells are not trypsin. But we have also evidence that these granules consist of material which, upon a very slight change, becomes trypsin, of material which is an antecedent of trypsin, and which has accordingly been called "trypsinogen." Thus the cell during rest stores up trypsinogen, and the change which characterizes activity is the conversion of trypsinogen into trypsin, and its consequent discharge from the cell. These are facts ascertained by observation and experiment, viz., that trypsinogen appears

in the protoplasm of the cell, and that in the act of secretion this trypsinogen is discharged from the cell in the form of the simpler trypsin. When, however, we come to consider the origin of the trypsinogen we pass to matters of inference and to a certain extent of speculation.

Two views seem open to us. On the one hand, we may adopt an old theory, once generally accepted, and suppose that the cell picks out from the lymph which bathes it particles of trypsinogen, or particles of some substance which is readily transformed into trypsinogen, and deposits them in its substance. This may be called the "selective" theory. On the other hand, we may suppose that the trypsinogen results from the breaking down, from the katabolic or destructive metabolism of the protoplasm, being thus wholly formed in the cell. This may be called the "metabolic" theory. Our present knowledge does not permit us wholly to prove or wholly to disprove either of these theories; but such evidence as we possess is in favour, and increasingly in favour, of the metabolic theory. All efforts to detect in the blood or in the lymph such substances as trypsinogen, or analogous substances in the case of other glands, have hitherto failed; and, although such a negative argument has its weakness, still it is of avail as far as it goes. On the other hand, the diminution of the protoplasm in the pancreatic cell, *pari passu* with the increase of trypsinogen, and its subsequent renewal previous to the formation of new trypsinogen, strongly support the metabolic theory, and a number of other facts drawn from the history of various animal and vegetable cells all tend strongly in the same direction. We have further a certain amount of evidence that trypsinogen arises from an antecedent more complex than itself, as it in turn is more complex than trypsin. So, although clear demonstration is not as yet within our reach, we may with considerable confidence conclude that trypsinogen and other like products of secreting cells arise from a breaking down of the cell-substance, are manufactured by the protoplasm of the cell out of itself.

Meso-  
states.

We are thus led to the conception that the specific material of a secretion, such as the trypsin of pancreatic juice, comes from the protoplasm of the cell, through a number of intermediate substances, or *mesostates* as they are called; that is to say, the complex protoplasm breaks down into a whole series of substances of decreasing complexity, the last term of which is the specific substance of the secretion. Now the protoplasm is undoubtedly formed at the expense of the material or pabulum brought to it from the blood through the medium of the lymph; the pabulum becomes protoplasm. Here also two views are open to us. On the one hand, we may suppose that the crude pabulum is at once by a magic stroke, as it were, built up into the living protoplasm. On the other hand, we may suppose that the pabulum reaches the stage of protoplasm through a series of substances of increasing complexity and instability, the last stage being that which we call protoplasm. And here, too, no absolute decision between the two views is possible, but such evidence as we do possess is in favour, and increasingly in favour, of the latter view.

Ana-  
states  
and  
kata-  
states.

We may therefore with considerable confidence anticipate the future arrival of evidence which will demonstrate the as yet only probable view that in the secreting cell there are two series of events, two staircases, as it were, of chemical transformation,—one an ascending staircase of synthetic, anabolic processes through which the pabulum, consisting of several substances, some of them already complex and unstable, is built up into the still more complex and still more unstable protoplasm; the other a descending staircase, consisting of a series of katabolic processes giving rise to substances of decreasing complexity and increasing

stability. The substances or mesostates appearing in the former we may speak of as "anastates," those of the latter we may call "katastates." At each step of the former, by which a simpler anastate becomes, or by which simpler anastates become, a more complex one, energy is absorbed; at each step of the latter energy is set free. And, since in the animal-cell the initial anastates seem always or at least generally more complex than the final katastates, the total life of the animal-cell is virtually a giving forth of energy.

So far we have spoken of the secreting cell, but we have Mole- evidence that in the activity of a muscle a similar series of events takes place. Reduced to theoretical simplicity, the unit a number of which go to form a muscle is a proto- plasmic cell, undergoing, like the secreting cell, a con- tinual metabolism, with a change in the results of that metabolism at the moment of functional activity. Put in a bald way, the main difference between a secreting cell and a muscle-cell, or elementary muscle-fibre as it is often called, is that in the former the products of the metabolism constitute the main object of the cell's activity, a change of form being of subordinate importance, whereas in the latter the change of form, an increase of one axis at the expense of another, a shortening with corresponding thick- ening, is the important fact, the products of the metabo- lism which thus gives rise to the change of form being of secondary value.

Now we have evidence, which, as in the case of the secreting cell, though not demonstrative, is weighty and of daily increasing weight, that the change of form, the contraction of a muscle, is due to a sudden metabolism, to an explosive decomposition of what may be called "contractile substance," a substance which appears to be used up in the act of contraction, and the consumption of which leads with other events to the exhaustion of a muscle after prolonged exertion. We know as a matter of fact that when a muscle contracts there is an evolution of a considerable quantity of carbonic acid, and a chemical change of such a kind that the muscle becomes acid. This carbonic acid must have some antecedent, and the acidity must have some cause. It is of course possible that the protoplasm itself explodes, and is the immediate parent of the carbonic acid and the direct source of the energy set free in the contraction; but evidence analogous to that brought forward in relation to the secreting cell leads to the conclusion that this is not so, but that the explosion takes place in, and that the energy is derived from, a specific contractile substance. And there is further evidence that this hypothetical substance, to which the name of "inogen" has been provisionally given, is, like its analogue in the secreting cell, a katastate. So that the contracting activity of a muscular fibre and the secreting activity of a gland-cell may be compared with each other, in so far as in each case the activity is essentially a decom- position or explosion, more or less rapid, of a katastate, the inogen in the one instance, the trypsinogen or some other body in the other instance, with the setting free of energy, which in the case of the secreting cell leaves the sub- stance wholly as heat, but in the case of the muscle partly as movement, the activity being followed in each case by the discharge from the fibre or cell of the products, or some of the products, of this decomposition.

Further, we may carry on the parallel to nervous sub- stance. As a nervous impulse travels along a nerve-fibre or pursues its intricate course along the fibrillar tracts of a nerve-cell, the amount of chemical change is too slight to be satisfactorily appreciated by the methods at present under our command. There is certainly no massive ex- plosion like that of a muscular fibre, and the most striking phenomena attending the passage of a nervous impulse are

In ner-  
vous sub-  
stance.

of an electrical nature. We cannot indeed distinctly prove that any chemical change does really accompany nervous activity; but from many considerations it is extremely probable that a chemical change, an explosive decomposition of more complex into more simple substances, is the basis of a nervous impulse. The energy, however, which is set free by this decomposition is not discharged from the nervous substance to so great an extent as is the case in the muscle-fibre, but is largely consumed in conveying or conducting the decomposition from one particle of the nervous substance to succeeding ones,—that is to say, in carrying out that which is the essential work of the nervous substance. Moreover, even in a muscle, while the explosion of inogen and the consequent shortening and thickening of the muscle-substance travel along the fibre from particle to particle in the form of a wave starting from the junction of the nerve-fibre with the muscular fibre, or from some other point of stimulation, this wave of visible contraction is preceded by invisible molecular changes also travelling along the fibre in the form of a wave, changes which manifest themselves by no massive explosions, which are indicated by electrical phenomena chiefly, and which are exceedingly like the nervous impulses of proper nervous structures. In the very substance of the muscular fibre there appears to be a material which is not inogen, but which is capable of undergoing changes, probably of the nature of an explosive decomposition, and it is these which in turn induce the more massive decomposition of the inogen. It is possible, indeed probable, that the constituent particles of inogen are not able to communicate their explosions to each other, so that the presence in the muscular fibre of an impulse-carrying material is a necessity. Be this as it may, a change antecedent to the explosion which is the cause of the actual contraction does occur in every particle of the muscle which contracts, and, as we have urged, the change is probably one taking place in a special substance. This substance may be the veritable protoplasm itself of the fibre, but considerations analogous to those urged before would lead us to suppose that it too is a katastate, but a katastate different in qualities from inogen; and we may further suppose that a very similar katastate is manufactured by nervous protoplasm, and by its decomposition gives rise to nervous energy. This katastate is, as it were, the fuse or trigger whose action fires the massive charge of the muscular gun, and might receive the name of "apheter."

If we accept this view as to the nature of the simple nervous impulses which sweep along nerve-fibres—and in this respect motor and sensory nerves would seem wholly alike—there is no great difficulty in extending the conception to the more complicated processes taking place in the central nervous system. An ordinary reflex act, so called, is perhaps one of the simplest labours of that system, and we have evidence that in a reflex act sensory impulses arriving along a sensory fibre at the protoplasm of a nerve-cell induce in that protoplasm changes which, though in certain respects differing from, are fundamentally analogous to, those changes in motor and sensory nerve-fibres which constitute their respective nervous impulses. The chief difference is that, whereas along sensory and motor fibres the impulses pursue an even course, possibly undergoing some augmentation, but one which is not sufficiently marked to be beyond doubt, in the nerve-cell, on the contrary, an unmistakable augmentation accompanied by a systematic dispersion takes place. So great is the augmentation in some cases that a gentle short series of sensory impulses reaching one of a group of nerve-cells along a single sensory fibre may throw the whole group of nerve-cells into such profound agitation that repeated series of even violent impulses may be discharged along a multitude of

motor fibres. Allowing for this increase in the energy set free, the changes in the nerve-cells do not seem to differ fundamentally from those in the nerve-fibres (which indeed differ to a certain extent among themselves), and may, like them, be regarded as due essentially to the decomposition of some katastate or katastates.

Further, just as the aphetor of the muscular fibre, that which inaugurates the explosion of the contractile inogen, differs from the aphetor of the nerve-fibre, so we may suppose that in the various nerve-cells of different parts of the central nervous system difference of function, while partly due to the mere arrangement and distribution of nervous impulses of the same kind, is also and more largely due to difference in the kind of impulses brought about by difference in the composition and mode of decomposition of the nervous material. For instance, certain changes in the nervous system are accompanied by distinct changes of consciousness, while others are not. And, while we may justly refuse to attempt any explanation of consciousness, Con. it is nevertheless within our right to suppose that, in that conscious-ness, nervous substance which is the highest development of protoplasm and to whose service the whole body ministers, amid the many substances of increasing complexity and dignity which enter into its composition there should be a substance or some substances the changes in which are, or may be, accompanied by consciousness. The doctrine of evolution compels us to admit that consciousness must be potentially present in the simple protoplasm of the amceba, and must be similarly present in all the tissues of the highly-developed animal, instead of being confined to some limited portion of the nervous system. Evolution refuses to admit a sharp line of demarcation between a "conscious" and a "non-conscious" part, and this decision is increasingly supported as our knowledge of the nervous system advances. But a great deal of the earlier part of this article was directed to show that all the powers of the complex animal are the outcome of the differentiation of a primordial protoplasm, while the discussion concerning the molecular changes of tissues in which we are now engaged is simply an attempt to trace out how that differentiation has taken place. And, as far as we can see, there are no just reasons why the differentiation which sets apart the nervous tissue from other parts of the body should not obtain in the nervous tissue itself, and the obscure rudiments of consciousness present in all nervous material become by differentiation developed, in some particular kinds of nervous substance, into consciousness more strictly so called.

In the case, then, of secreting cells, of muscular tissue, and of the various forms of nervous tissue the tendency of inquiries into the molecular processes taking place in them is to lead us to regard the varied activities of these tissues as due to molecular disruptive changes in their several katastates, these being various stages of the downward metabolism or katabolism of protoplasm.

Similar considerations might be extended to other tissues of the body which are neither nervous nor muscular, and, though engaged in chemical work, are not distinctly secretory or excretory, such, for instance, as the hepatic cells engaged in the elaboration of glycogen. They might also be extended to those tissues in which the katastates are not exploded and discharged, but retained and massed up in the body for mechanical or other purposes, to cartilage, for instance, the chondrogenous basis or ground-substance which many considerations show to be a product or katastate of protoplasm. We are thus led to the conception, brought forward in an earlier part of this article, that all over the body protoplasm is continually building itself up out of the pabulum supplied by food, and continually breaking down, giving rise in different tissues and

different parts of the body to different katasates with different composition and different properties, the various activities of the body being the outcome of the various properties of the various katasates. If this be admitted, it almost inevitably follows that what we have called protoplasm cannot be always the same thing, that there must be many varieties of protoplasm with different qualities and with correspondingly different molecular structure and composition. If this be so, the question naturally arises, why use the word protoplasm at all, since, by the showing, it seems to have no exact meaning? But it has an exact meaning. All the evidence at our disposal goes to show that a katasate of any given degree cannot form a fresh katasate of the same degree; any one katasate can only arise from the decomposition of a preceding more complex katasate, and that in turn from a katasate still more complex. Passing upwards, we come at last to something which, instead of proceeding from a more complex substance, builds itself up out of a less complex, more simple substance, and it is this something, whatever its exact composition, into whatever katasates it is destined to fall asunder, to which the generic name "protoplasm" should be given. Possibly another new name were better, but there are advantages in retaining the old term. It is protoplasm in this sense which is alone *living*; it is its synthetic power which is its token of being alive. That synthetic power is, we must admit, exercised along the ascending series of anastates. But here our knowledge is a blank; and it would be simply waste of time to speculate as to the details of the constructive processes. Using the word "protoplasm" in this sense, it is obvious that the varieties of protoplasm are numerous, indeed almost innumerable. The muscular protoplasm which brings forth a contractile katasate must differ in nature, in composition—that is, in construction—from glandular protoplasm, whose katasate is a mother of ferment. Further, the protoplasm of the swiftly contracting striped muscular fibre must differ from that of the torpid smooth unstriated fibre; the protoplasm of human muscle must differ from that of a sheep or a frog; the protoplasm of one muscle must differ from that of another muscle in the same kind of animal; and the protoplasm of Smith's biceps must differ from that of Jones's.

We may, for a moment, turn aside to point out that this innate difference of protoplasm serves to explain the conclusions to which modern investigations into the physiology of nutrition seem to be leading. So long as we speak of muscle or flesh as one thing, the step from the flesh of mutton which we eat to the flesh of our body which the mutton, when eaten, becomes, or may become, does not seem very far; and the older physiologists very naturally assumed that the flesh of the meal was directly, without great effort and without great change, as far as mere chemical composition is concerned, transformed into the muscle of the eater. The researches, however, of modern times go to show that the substances taken as food undergo many changes and suffer profound disruption before they actually become part and parcel of the living body, and conversely that the constructive powers of the animal body were grossly under-rated by earlier investigators. If one were to put forward the thesis that the proteid of a meal becomes reduced almost to its elements before it undergoes synthesis into the superficially similar proteid of muscle, the energy set free in the destruction being utilized in the subsequent work of construction, he might appeal with confidence to modern results as supporting him rather than opposing him in his views. It would almost seem as if the qualities of each particle of living protoplasm were of such an individual character that it had to be built up afresh from almost the very beginning; hence the im-

mense construction which inquiry shows more and more clearly every day to be continually going on as well in the animal as in the vegetable body.

Taking into consideration all the fine touches which make up the characters of an individual organism, and remembering that these are the outcome of the different properties or activities of the several constituent tissues of the body, working through a delicately-balanced complicated machinery, bearing in mind the far-reaching phenomena of heredity by which the gross traits and often the minute tricks of the parents' body are reproduced in the offspring, if there be any truth at all in the views which we have urged, tracing the activities of the organism to the constitution of its protoplasm, this must be manifold indeed. The problems of physiology in the future are largely concerned in arriving, by experiment and inference, by the mind's eye, and not by the body's eye alone, assisted as that may be by lenses yet to be introduced, at a knowledge of the molecular construction of this protean protoplasm, of the laws according to which it is built up, and the laws according to which it breaks down, for these laws when ascertained will clear up the mysteries of the protean work which the protoplasm does.

And here we may venture to introduce a word of caution. We have, in speaking of protoplasm, used the words "construction," "composition," "decomposition," and the like, as if protoplasm were a chemical substance. And it is a chemical substance in the sense that it arises out of the union or coincidence of certain factors, which can be resolved into what the chemists call "elements," and can be at any time by appropriate means broken up into the same factors, and indeed into chemical elements. This is not the place to enter into a discussion upon the nature of so-called chemical substances, or, what is the same thing, a discussion concerning the nature of matter; but we may venture to assert that the more these molecular problems of physiology, with which we are now dealing, are studied the stronger becomes the conviction that the consideration of what we call "structure" and "composition" must, in harmony with the modern teachings of physics, be approached under the dominant conception of modes of motion. The physicists have been led to consider the qualities of things as expressions of internal movements; even more imperative does it seem to us that the biologist should regard the qualities (including structure and composition) of protoplasm as in like manner the expression of internal movements. He may speak of protoplasm as a complex substance, but he must strive to realize that what he means by that is a complex whirl, an intricate dance, of which what he calls chemical composition, histological structure, and gross configuration are, so to speak, the figures; to him the renewal of protoplasm is but the continuance of the dance, its functions and actions the transferences of figures. In so obscure a subject it is difficult to speak otherwise than by parables, and we may call to mind how easy it is to realize the comparison of the whole body of man to a fountain of water. As the figure of the fountain remains the same though fresh water is continually rising and falling, so the body seems the same though fresh food is always replacing the old man which in turn is always falling back to dust. And the conception which we are urging now is one which carries an analogous idea into the study of all the molecular phenomena of the body. We must not pursue the subject any further here, but we felt it necessary to introduce the caution concerning the word "substance," and we may repeat the assertion that it seems to us necessary for a satisfactory study of the problems on which we have been dwelling for the last few pages to keep clearly before the mind the conception that the phenomena in question are the result not of properties of kinds of

matter, in the vulgar sense of these words, but of kinds of motion.

In the above brief sketch we have dealt chiefly with such well-known physiological actions as secretion, muscular contractions, and nervous impulses. But we must not hide from ourselves the fact that these grosser activities do not comprise the whole life of the tissues. Even in the simple tissues, and more especially in the highly-developed nervous tissues, there are finer actions which the conception outlined above wholly fails to cover.

Finer  
activities  
of proto-  
plasm.

Two sets of vital phenomena have hitherto baffled inquirers,—the phenomena of spontaneous activity, rhythmic or other, and the phenomena of "inhibition." All attempts to explain what actually takes place in the inner working of the tissues concerned when impulses passing down the pneumogastric nerve stop the heart from beating, or in the many other analogous instances of the arrest of activity through activity, have signally failed; the superficial resemblance to the physical "interference of waves" breaks down upon examination, as indeed do all other hypotheses which have as yet been brought forward. And we are wholly in the dark as to why one piece of protoplasm or muscular fibre or nervous tissue remains quiescent till stirred by some stimulus, while another piece explodes into activity at rhythmic intervals. We may frame analogies and may liken the phenomena to those of a constant force rhythmically overcoming a constant resistance, but such analogies bring us very little nearer to understanding what the molecules of the part are doing at and between the repeated moments of activity.

Hering's  
speculations.

Further, if the ingenious speculations of Hering, that specific colour-sensations are due to the relation of assimilation (anabolism) to dissimulation (katabolism) of protoplasmic visual substances in the retina or in the brain, should finally pass from the condition of speculation to that of demonstrated truth, we should be brought face to face with the fact that the mere act of building up or the mere act of breaking down affects the condition of protoplasm in other ways than the one which we have hitherto considered, viz., that the building up provides energy to be set free and the breaking down lets the energy forth. In Hering's conception the mere condition of the protoplasm, whether it is largely built up or largely broken down, produces effects which result in a particular state of consciousness. Now, whatever views we may take of consciousness, we must suppose that an affection of consciousness is dependent on a change in some material. But in the case of colour-sensations that material cannot be the visual substance itself, but some other substance. That is to say, according to Hering's views, the mere condition of the visual substance as distinct from a change in that condition determines the changes in the other substance which is the basis of consciousness. So that, if Hering's conception be a true one (and the arguments in favour of it, if not wholly conclusive, are at least serious), we are led to entertain the idea that, in addition to the rough propagation of explosive decompositions, there are continually passing from protoplasm to protoplasm delicate touches compared with which the nervous impulses which with such difficulty the galvanometer makes known to us are gross and coarse shocks. And it is at least possible, if not probable (indeed present investigations seem rapidly tending in this direction), that an extension of Hering's view, with such modifications as future inquiry may render necessary, to other processes than visual sensations, more especially to the inner working of the central nervous system, may not only carry us a long way on towards understanding inhibition and spontaneous activity but may lay the foundation of a new molecular physiology. This, however, is speculative and dangerous ground. But it seemed

desirable to touch upon it since it illustrates a possible or probable new departure. What we have said of it and of the more manageable molecular problems of physiology will perhaps show that, vast and intricate as is the maze before the physiologist of to-day, he has in his hand a clue which promises, at least, to lead him far on through it.

Space forbids our entering upon a discussion concerning the methods of physiology; but, accepting the truth of the preceding discussion as to the nature of physiological problems, the means of solving these problems speak for themselves.

From the earliest times the methods of physiological inquiry have belonged to one of two categories: they have been anatomical or experimental. And the same distinction holds good to-day, though both methods are often joined together in one inquiry, and indeed at times may be said to merge the one into the other. By the anatomical method the observer ascertains the gross outlines, the minute structure, and if necessary the physical characters and the chemical composition of an organism or part of an organism; and by comparison of these with those of different organisms, or of the same organism placed by nature—that is, not by himself—in different circumstances, he draws conclusions as to the actions taking place in it while it was alive. In early times the comparison of gross structures gave important results, but they have now been to a great extent exhausted; and the most valuable conclusions reached at the present day by the anatomical method are those arrived at by histological investigation of minute structures and by chemical analysis. The marks of this method are that on the one hand it deals for the most part with things which are no longer alive, and hence must necessarily fail to make touch with the inner workings of which we have spoken above, and on the other hand in its comparison of organisms under different conditions it has to wait till Providence brings about what it requires, and has to be satisfied with such differences as the chapter of accidents provides. In the experimental method the observer places the organism or part of the organism under conditions of his own choosing, and applies to the organism under those conditions the same analysis as in the former methods. He ascertains changes in the gross features, minute structure, physical characters, and chemical composition, as before. So that in reality the two methods are in part identical, and differ chiefly by the fact that in the latter the observer chooses the conditions in which to place the organism. But an important corollary follows, viz., that by choosing his own conditions the observer is able to bring his analysis to bear on an organism or part of an organism while still alive.

The history of physiology, especially in recent times, shows that this method is the one not only of the greatest fertility but one becoming more and more essential as inquiry is pushed deeper and deeper into the more abstruse parts of physiology. If there be any truth in the sketch given above of the modern tendencies of molecular physiology, it will be clear to every mind that the experimental method alone can in the future give adequate results. It might indeed be urged that when molecular physics has advanced far enough the molecular problems of physiology will be interpreted by its light without recourse to experiment. It will be a long waiting till that comes. Meanwhile, all the power over not only the body but, what is more important, the mind of man which the physiology of the future unmistakably promises must lie unused. Nor is it simply a matter of waiting, for it is at least within the range of possibility that when the molecular problems of physiology are fairly grasped conclusions may be reached which will throw back a light on the molecular processes of inanimate masses, revealing features of what we call

"matter" which could not be discovered by the examination of bodies which had never lived.

Value of experimental method. It would not be a hard task to give chapter and verse for the assertion that the experimental method has, especially in these later times, supplied the chief means of progress in physiology; but it would be a long task, and we may content ourselves with calling attention to what is in many respects a typical case. We referred a short time back to the phenomena of "inhibition." It is not too much to say that the discovery of the inhibitory function of certain nerves marks one of the most important steps in the progress of physiology during the past half-century. The mere attainment of the fact that the stimulation of a nerve might stop action instead of inducing action constituted in itself almost a revolution; and the value of that fact in helping us on the one hand to unravel the tangled puzzles of physiological action and reaction, and on the other hand to push our inquiries into the still more difficult problems of molecular changes, has proved immense. One cannot at the present time take up a physiological memoir covering any large extent of ground without finding some use made of inhibitory processes for the purpose of explaining physiological phenomena.

Now, however skilfully we may read older statements between the lines, no scientific—that is, no exact—knowledge of inhibition was possessed by any physiologist until Weber, by a direct experiment on a living animal, discovered the inhibitory influence of the pneumogastric nerve over the beating of the heart. It was of course previously known that under certain circumstances the beating of the heart might be stopped; but all ideas as to how the stoppage was or might be brought about were vague and uncertain before Weber made his experiment. That experiment gave the clue to an exact knowledge, and it is difficult, if not impossible, to see how the clue could

have been gained otherwise than by experiment; other experiments have enabled us to follow up the clue, so that it may with justice be said that all that part of the recent progress of physiology which is due to the introduction of a knowledge of inhibitory processes is the direct result of the experimental method. But the story of our knowledge of inhibition is only one of the innumerable instances of the value of this method. In almost every department of physiology an experiment or a series of experiments has proved a turning-point at which vague nebulous fancies were exchanged for clear decided knowledge, or a starting-point for the introduction of wholly new and startling ideas. And we may venture to repeat that not only must the experimental method be continued, but the progress of physiology will chiefly depend on the increased application of that method. The more involved and abstruse the problems become, the more necessary does it also become that the inquirer should be able to choose his own conditions for the observations he desires to make. Happily, the experimental method itself brings with it in the course of its own development the power of removing the only valid objection to physiological experiments, viz., that in certain cases they involve pain and suffering. For in nearly all experiments pain and suffering are disturbing elements. These disturbing elements the present imperfect methods are often unable to overcome; but their removal will become a more and more pressing necessity in the interests of the experiments themselves, as the science becomes more exact and exacting, and will also become a more and more easy task as the progress of the science makes the investigator more and more master of the organism. In the physiology of the future pain and suffering will be admissible in an experiment only when pain and suffering are themselves the object of inquiry. And such an inquiry will of necessity take a subjective rather than an objective form. (M. F.)

## PART II.—NERVOUS SYSTEM.

To supplement the foregoing general sketch some detailed account must be given of the physiology of the several functions. NUTRITION (*q.v.*) has received separate treatment; a sketch of the "Nervous System" is now appended; and RESPIRATION and REPRODUCTION will be dealt with in their places.

However complex may be the anatomical arrangements in man and the higher animals, the nervous system consists essentially of three portions: (1) *central* masses of nervous matter, or *ganglia*, constituting the brain and spinal cord, and containing invariably nerve-cells; (2) *peripheral* or *terminal* arrangements, existing in the organs of sense, in muscle, and in electric organs; and (3) *nerves*, or internuncial cords connecting the central with the peripheral organs. The nerves may be regarded as conductors of a mode of energy which, for want of a better term, is termed "nerve-force," originating either in the nerves themselves on the application of a stimulus or in the terminal organs or in the central organs. Thus, if a nerve be irritated at any point of its course, a change is set up in the nerve-fibres at the point of irritation, and this change is propagated along the nerve-fibres to a central or terminal organ, thus producing a characteristic phenomenon,—it may be a sensation of pain or of pleasure, an involuntary movement, the contraction of a muscle, or a discharge of electricity. Again, the stimulus may act on a terminal organ, such as the retina, setting up a change which is then propagated or conveyed to the brain by the optic nerve, there giving rise to a sensation of light or colour. Finally, the nervous action may originate in a central organ, as is the case when a voluntary movement is made. The voluntary impulse, in this instance, originates in the brain; a change passes along nerve-fibres from the brain to the muscles, and as a result the muscles contract. We have therefore to discuss the general properties and modes of action of nerves, terminal organs, and central organs.

### 1.—NERVES.

Structure of Nerves. A general description of the structure of nerves and of nerve-fibres will be found in vol. i. p. 859 *sq.*; but there are a few points of physiological importance still to be noticed. Two kinds of nerve-fibres exist in the body, white or medullated fibres, so called because each fibre has a sheath indicated by a double contour (see fig. 1), and the pale or non-medullated. The medullated nerve-fibres form the white part of the

brain, spinal cord, and nerves. They vary in diameter from the  $\frac{1}{1000}$ th to the  $\frac{1}{100}$ th of an inch, and when of very small size often show varicosities or swellings. Each fibre consists of three parts:

(1) an external sheath, or primitive sheath; (2) within this the medullary sheath or white substance of Schwann; and (3) in the centre an axial fibre, the cylinder axis of Purkinje, or band of Remak. The axis-cylinder in a fresh nerve seems to be homogeneous; but with high powers and proper illumination, and more especially

Fig. 1.

Fig. 2.

FIG. 1.—(1) Medullated nerve-fibres, showing double contour; (2) a similar fibre in which A is primitive membrane, B medullary sheath, C axial cylinder protruding beyond the broken end of the fibre; (3) transverse section through medullated fibres of a nerve showing axial cylinder in each fibre. Between the fibres is the interfibrillar connective tissue.

FIG. 2.—Medullated nerve-fibres. A, medullated nerve-fibre, showing sub-division of medullary sheath into cylindrical sections imbricated with their ends; a nerve-corpuscle with an oval nucleus is seen between neurilemma and medullary sheath; B, medullated nerve-fibre at a node or constriction of Ranvier; the axis-cylinder passes uninterruptedly from one segment into the other, but the medullary sheath is interrupted. (Key and Retzius.)

by the action of perosmic acid, it is seen to be formed of extremely fine fibrillae. It is continuous from end to end of the nerve. The medullary sheath shows at certain intervals interruptions called the "nodes of Ranvier" (see fig. 2). In the middle of each internode an oval nucleus is found in the medullary sheath. The pale or non-medullated fibres, sometimes called the "fibres of

Remak." are found chiefly in branches of the sympathetic nerve. They have no double contour, and they often give off branches which anastomose, a condition never found in the course of medullated nerves. If the axis-cylinder of a nerve-fibre be traced inwards to a nerve-centre it is found to end in the pole or process of a nerve-cell, whilst in the periphery it ends in a terminal organ, in muscle, blood-vessel, gland, skin, or electric organ. It may therefore be presumed that the axis-rod is the conducting and so far the essential constituent of the nerve-fibre.

**Chemical constitution.**—Little is known of the chemical constitution of the nerve-fibre. The medullary matter contains fatty substances such as lecithin ( $C_{41}H_{82}NPO_8$ ). The axis-rod appears to contain albuminous substances. Cholesterol ( $C_{27}H_{46}O + H_2O$ ) and creatin ( $C_4H_7N_3O_2$ ) have been obtained from nerves along with a small amount of gelatin and a horny matter, neurokeratin (Hermann). Nerves contain about 30 per cent. of water. Their reaction to test-paper is neutral. Nothing is known regarding the chemical changes occurring in a nerve-fibre during a state of activity, nor of the chemical products formed at that time. It has been stated that a nerve becomes acid after death (Funke).

As to the micro-chemistry of the nervous elements, it may be stated that the axis-cylinder contains an albuminous substance different from myosin; it gives a red color on boiling with Milton's reagent (an acid nitrate of mercury); it is dissolved in weak solutions of ammonia, caustic potash, and chloride of sodium; it is hardened by solutions of chromic acid, bichromate of potash, and corrosive sublimate; it reduces the chloride of gold; and it shows transverse markings on the action of nitrate of silver. The white substance (Schwann) is blackened by perchromic acid and is soluble in alcohol, ether, and oil of turpentine, thus showing its fatty character. The primitive sheath is a substance of a collagenous nature,—that is, it yields gelatin on boiling. According to some, digestion in gastric or pancreatic juice leaves an insoluble matter like that found after the digestion of corneal or epidermic tissues, and hence called "neurokeratin."

**Excitability.**—The special property of a nerve-fibre is termed "excitability." Every kind of living protoplasmic matter is irritable,—that is, it responds in some way to a stimulus. Thus, if a morsel of protoplasm, such as an amoeba or a cartilage-cell or a white blood-corpuscle, be stimulated mechanically or by shocks of electricity, it will contract or change its form. Again, if living muscular fibre be thus stimulated it also will contract. This property of responding to a stimulus is termed "irritability"; and in the structures mentioned the property is manifested by movement as the obvious phenomenon, but it is well known that more obscure phenomena follow the application of the stimulus. In the case of living nerve there is irritability also,—that is, the nerve responds to a stimulus; but in a portion of isolated nerve no change is visible. If, however, the nerve be connected at one end with its appropriate central or terminal organ we may have evidence of something having been transmitted along the nerve. Thus there may be sensation or movement, or both. Nerves are more irritable than contractile matter, and the term "excitability" is applied to the special irritability of nerve. The same strength of stimulus will act more powerfully on a nerve than on a muscle (Rosenthal). The use of the term "property" in physiology does not imply the idea of any kind of inherent force or entity, but simply that, in the case of muscle and nerve, irritation is followed by certain phenomena seen

salts; (d) electrically, by continuous or induced currents; and (e) normally, by changes in the central or terminal organs. Mechanical irritation is applied during life when the trunk of a nerve is pressed upon. Radiant heat acts on the nerves of the skin, or heat may be applied by conduction from a hot body in contact with the surface. Little is known as to the specific effects of heat on the nerves of the human being. In the frog it has been found that a temperature of from  $34^{\circ}$  to  $45^{\circ}$  C. stimulates the motor nerves; about  $40^{\circ}$  C. sudden alterations of temperature may cause twitching of the connected muscles (Hermann). Many chemical substances in sufficient concentration will quickly destroy a nerve; but if they are in weak solutions the result may be stimulation. Thus, concentrated solutions of the mineral acids, alkalis, alkaline salts, concentrated lactic acid, and concentrated glycerin may act as strong stimulants (Kühne).

(3.) The influence of electrical stimulation of nerves demands more elaborate description. The effects, as already indicated, can be observed only when the nerve is connected with a muscle or with a central organ. In the first case electrical stimulation is followed by contraction of the muscle, in the second by a sensation if the central organ is the brain. Consequently we have to consider the phenomena following electrical stimulation (a) of a motor nerve and (b) of a sensory nerve.

(a.) **Electrical Stimulation of a Motor Nerve.**—A perfectly constant current of electricity, of moderate quantity and intensity, trical flowing through a portion of nerve produces no evident effect on stimulate the muscle, but any variation in the intensity or density of the electric current causes irritation, and the muscle gives a twitch. The motor effect is most apparent when the current is allowed to flow into nerve the nerve and when it is suddenly cut off, or, in other words, at the moment of opening and of closing the circuit. The rapidity with which the variation in the density of the current is effected also has an important influence. Thus the shocks of frictional electricity stimulate strongly, because, although the amount of electricity is small, the currents are extremely rapid in appearing and disappearing. In like manner the quick shocks from induction-coils produced by rapidly opening and closing the primary circuit are strongly stimulating. Again, a very powerful current may pass through a nerve without exciting it, if it pass gradually. Occasionally a very weak current sent through a portion of nerve will cause a contraction, whilst a very strong current may fail to do so. In fact, the phenomenon of contraction of a muscle is influenced (a) by the direction and (b) by the strength of the current sent through the nerve. When the current is transmitted from the muscle in the direction of the spinal cord it is called an "upward" or "centripetal" current, when from the cord in the direction of the muscle it is called a "downward" or "centrifugal" current. Its strength is graduated by employing small Grove's cells, one cell giving a weak current, two or three giving a medium current, and four to six or seven a strong current. To graduate its amount more precisely resistance-coils may be introduced into the circuit, or we may employ a rheochord, by which a portion of the current is shunted back to the battery, whilst the remainder is allowed to pass to the nerve. In the circuit a key or interrupter is interposed, and so arranged that when the key is opened the current is broken or interrupted, and when the key is closed the circuit is completed and the current passes to the nerve. With these arrangements, and employing the sciatic nerve of a frog attached to the limb, the following results are readily obtained.

Current Strength.	Key.	Upward Current.	Downward Current.
Weak.	Close.	Contraction.	Contraction.
Weak.	Open.	Rest.	Rest.
Medium.	Close.	Strong contraction.	Strong contraction.
Medium.	Open.	Strong contraction.	Strong contraction.
Strong.	Close.	Rest.	Rest.
Strong.	Open.	Very strong contraction.	Contraction.

That is to say, on beginning with a very feeble current neither opening nor closing causes a contraction, but on strengthening it up to a certain point contraction appears first on closing, whilst opening produces no effect. By increasing the strength of the current a contraction is obtained both on opening and on closing the key, and by and by, when a certain strength of current is reached, the closing contraction becomes weaker and finally disappears, leaving only a contraction on opening the key. Thus the effects of a strong current are usually the reverse of those caused by a weak current. These facts, usually included under the term "Pflüger's Law of Contraction," have been specially investigated by Pflüger, and the following is the explanation offered by him and generally accepted by physiologists.

Suppose that the sciatic nerve of a frog connected with the isolated limb is stretched over two wires passing from the positive and negative poles of a combination of Grove's elements, with the distance of an inch and a half between the wires. If a key be interposed in the circuit a current will thus pass along one and a half inches of nerve when the key is closed, and be cut off when the key is opened. By having also a commutator or reverser in the circuit we can send the current up or down the nerve at pleasure. Arrangements can also be made for irritating the nerve by another couple of wires coming from an induction-machine, either near the negative or near the positive pole of the current coming from the Grove's elements. It will then be found that near the negative pole the excitability of the nerve is increased, whilst near the

to the muscle A, the muscle stimulated contracts, and draws by means of the stylet, on the smoked surface of the glass, the curve seen in the lower part of it at A. This leaves the horizontal line (which would be drawn by the stylet were the muscle at rest) at A. Arrangements are then made for another experiment, in which the nerve will be stimulated at a distance from the muscle, at the point B in the upper part of the diagram. This is done by again placing the smoked-glass plate in proper position, closing the primary circuit by the brass arm at the binding screws, as already described, and reversing the commutator so as to send the shock along the wires to B. The muscle again contracts when the primary circuit is opened, and this time it describes on the smoked surface the curve B, seen to the left of the curve A. It will be perceived that this curve leaves the horizontal line at B,—that is, a little later than when the nerve was stimulated close to the muscle. It follows, therefore, that the distance on the horizontal line from A to B represents the time occupied by the transmission of the nervous impulse from B to A of the nerve. With suitable arrangements, the rate of movement of the glass plate can be measured by bringing into contact with it a marker on one of the prongs of a vibrating tuning-fork. The waves thus recorded enable the experimenter to measure with accuracy the rate of movement of the glass plate, and consequently the minute interval of time between A and B. In the diagram it will be observed that there are 2½ waves between A and B; each represents 1/10th of a second; therefore the 1/4th of a second is the time represented by the distance A, B; or, in other words, the 1/4th of a second was occupied by the nerve-current in passing along the portion of nerve from B to A.

(2.) *Measurement of Velocity in Sensory Nerve.*—The theory of nervous excitation in the hand; the theory of nervous propagation along the nerve to the brain, and changes occur which result in a sensation. The individual having the sensation may feel it and make no sign by which any one else might be made aware that he has felt it, or the subject of the sensation might, by a muscular movement, such as the motion of an arm, let any one else see that he has felt the sensation. We have no means of knowing whether or not an individual has felt a sensation except by the individual making some kind of gesture or muscular movement. Now it is clear that, if we regard the brain as the seat of the changes resulting in sensation, the nearer any stimulated portion of skin is to the brain the sooner will the brain feel and respond to the stimulus. Thus, if the skin on the big toe of the right foot be stimulated, the effect of the stimulus passes to the brain and there calls forth a sensation, but if the stimulus be applied to the skin at the top of the thigh it is evident the effect has to pass along a shorter length of nerve and that the sensation in the brain will be aroused sooner. If we suppose that in each case the individual who is the subject of the experiment indicates the moment he feels the sensation, and that the instant the stimulus is applied successively to the skin on the toe and on the thigh is also accurately recorded, it is clear that he will signal the sensation of stimulation of the toe a little later than when he signals stimulation of the skin on the thigh, and that the difference will indicate the time required by the change in the nerve to pass along the length of nerve from the toe to the thigh. In the observation it is assumed that the time required for the changes in the brain resulting in sensation and volition, for the transmission along the motor nerve, and for the muscular contraction, for the signal, is the same in each experiment. Thus, if the time required for the passage of the nerve-current in the first experiment from the toe to the brain, of  $b$ , the time required for the changes in the brain involved in sensation and volition, and of  $c$ , the time required for the transmission along the motor nerves and for the muscular contraction to move the signal,—that is,  $x = a + b + c$ . But, if the time between the moment of stimulating the thigh to the moment of the signal,  $y$ , is the time between the moment of stimulating the thigh to the moment of the signal,  $y = a + b + c$ . Suppose the difference of time between the two experiments is  $z$ , then  $z = x - y = a + b + c - (a + b + c)$ ,—that is,  $z = 0$ . This method has also been used to measure the time required for signalling a nervous impression in various circumstances, or what is usually called the "reaction period." The most convenient apparatus for the purpose is a chronograph made by König of Paris, the instrument being fully described in *McKendrick's Outlines of Physiology*, pp. 538-542.

The general result of measurements made by these methods is that the nerve-current travels slowly compared with the velocity of electricity or of light. In the motor nerves of the frog the velocity is about 57 feet (20 to 27 metres) per second, and in man and warm-blooded animals somewhat faster, 115 to 130 feet (35 to 40 metres) per second. The results as to velocity in sensory nerves vary from 50 to 100 metres per second. Cold retards, heat accelerates, the velocity. As already stated, the velocity is also retarded in a nerve in an anelectrotonic, and accelerated in a katelectrotonic state. The remarkable point is that the transmission of the nerve-current is slow, and that events appearing to our consciousness instantaneous require a considerable time for their occurrence. It may be laid down as a general truth that all kinds of nervous actions, even those considered as purely psychical, require time.

**Heat produced by nerves.**—*Production of Heat by Nerve.*—It is extremely doubtful whether the production of heat by a nerve in action has been detected, although theoretically one would expect heat to be so produced. Schill observed an increase of temperature on tetanization in the nerves of warm-blooded animals that had been artificially cooled; on the other hand, Helmholtz and Heidenhain's experiments yielded only negative results.

*Electrical Phenomena of Nerve.*—When a piece of nerve is properly brought into contact with the terminals of a sensitive galvanometer, a current flows through the galvanometer from the surface of the nerve to its transverse section (see fig. 4).

If metallic emitters, composed (say) of zinc, from the galvanometer were brought into connexion with a piece of nerve removed from an animal newly killed, little or no current would be obtained, and even if there were a current it might be due to contact of the metallic conductors with the living tissue creating electrolytic decomposition. Hence it is necessary to have a fluid in contact between the initial and the animal tissue, say, for example, the zinc wire or plate forming the terminals of the galvanometer is immersed in a saturated solution of sulphate of zinc. But as sulphate of zinc solution would have the effect of irritating the living muscle it is necessary to have an inactive substance between the tissue and the sulphate of zinc solution. All these conditions are fulfilled by the non-polarizable electrodes of Du Bois-

Reynoud, of which there are various forms. Two zinc troughs, mounted on insulating plates of vulcanite, have the inner surfaces carefully amalgamated. These are filled with a saturated solution of sulphate of zinc, and in each trough is placed a small cushion of clean blotting or filter paper, which quickly becomes permeated with the solution. Finally, a small plate of sculptor's clay, or kaolin, moistened with a half per cent. solution of common salt, or,

FIG. 4.—Diagram of apparatus of Du Bois-Reymond for experiments on electrical condition of muscle and nerve.  $a$ , zinc troughs, mounted on pieces of vulcanite  $b$ ;  $c$ , paper pads;  $d$ ,  $e$ , small pieces of moist clay;  $f$ ,  $g$ , binding screws for attaching terminals of galvanometer  $g$ . A small piece of paper connects  $d$  and  $e$ , and thus completes the galvanometer circuit. (Wundt.)

still better, with saliva, is laid on each paper pad. These clay pads are for guarding the tissue from the irritant action of the sulphate of zinc. Wires are carried from the troughs to the galvanometer, and a key is interposed in the circuit. The object of these careful arrangements is to secure that no current is formed by the apparatus itself. If now a small piece of nerve be so placed on the clay pads that the transverse section touches one pad and the longitudinal surface the other, and the key is opened, a current passes through the galvanometer, as indicated by the swing of the needle. Suppose that the needle is allowed to come to rest, the amount of deflection of course indicating the strength of the current, and the nerve is now irritated so as to call forth its physiological activity, then the needle swings back towards zero. This backward swing is called the negative variation of the nerve-current. The electromotive force of the current obtainable from a frog's sciatic nerve is about 0.22 of a volt, and somewhat more from the sciatic nerve of a rabbit. This is somewhat less than the electromotive force of a frog's muscle, which varies from 0.35 to 0.75 of a volt. According to the views of Hermann, the negative variation-current is a true current indicating, and indeed preceding, the physiological activity of the nerve. He denies that the currents pre-exist in nerve or muscle, and states that the first current observed when the nerve is laid on the pads is simply due to the lower potential of the transverse section, caused by the rapid death of the nerve-substance. The nerve-current excited by a series of irritations, say feeble induction-currents, may be regarded as composed of a wavelike series of momentary currents, each of which is preceded by a negative variation-current. Thus the electrical phenomena of nerve are similar in kind to those manifested by living muscle.

*Nutrition of Nerves.*—Probably nerves are nourished by the Nutri-plasma reaching the axis-cylinder at the nodes of Ranvier; but it is of importance to appear from the researches of Waller that the nutrition of nerves, the nerve-fibre is influenced by the nerve-cell with which it is connected. The so-called "law of Waller" is well illustrated in the case of division of the roots of the spinal nerves. Each of these nerves has two roots,—a posterior, sensory, on which there is a ganglion; and an anterior, motor. If the anterior root be divided, in the course of a few days the end of the nerve cut off from the spinal cord is found to be undergoing degeneration, whilst the end attached to the cord is still normal. Again, if the posterior root be divided between the ganglion and the cord, the end remaining in connexion with the ganglion remains unaffected, whilst the other end undergoes degeneration. This degeneration, in the case of a motor nerve, affects the nerve to its very terminations. The axis-cylinder disintegrates into drops of fatty matter, and the medullated structure entirely disappears. It is well known that when a nerve is cut the ends may reunite so completely as to ensure a return of the normal function in from two to five weeks. According to Ranvier, the axis-cylinders in connexion with the central portion play an important part in this regeneration. They become larger, striated, and by and by form new axis-cylinders, which pass into the divided nerve. This is a remarkable confirmation of the view of Waller that the nutritional activity of a nerve-fibre is in the direction of its physiological activity.

*Nature of Nerve-currents.*—The intrinsic nature of the change in a nerve-fibre effected by a stimulus is quite unknown; but it is currents, important to appreciate clearly the view that a nerve is both a receiver and a conductor of impressions. It can be stimulated in any part of its course, and from the stimulated point some kind of change is propagated along the nerve. This change is analogous to the passage of electricity along a conductor, or to the rapid passage onwards of a series of chemical decompositions, as when a thin band of gun-cotton properly prepared is seen to slowly burn from end to end, or to the quick transmission of isomeric changes; but the analogy is not complete in any case. Whatever

the change may be, however, it does not appear to pass from one nerve-fibre to another running alongside of it. Each fibre conducts only its own impression, and there is nothing analogous to the inductive effect of one electrical conductor upon an adjacent one. Another question much debated is whether sensory and motor nerves act in the same way; or, in other words, is there any essential difference between them? There appears to be no difference in mode of action; the difference in the effect produced depends on the apparatus in which the nerve ends. Thus there may be contraction of a muscle if the nerve terminates in a muscle, change of the calibre of a blood-vessel if the nerve ends in that structure, secretion from a gland if the nerve is in connexion either with the vessel or the nerve-cells of a gland, an electrical discharge if the nerve ends in the electrical organ of a *Torpedo* or *Gymnastus*, and a feeling or sensation if the nerve-fibres go to a sentient brain. In all these instances the nature of the change in the nerve and the mode of its transmission are the same, and the results are different because the nerves terminate in different kinds of structure. It would appear from experimental evidence that, when a nerve-fibre is irritated, say about the middle of its length, a change is simultaneously propagated towards each end; but, as only one end is in connexion with an apparatus capable of responding, the effect at this end is the only one observed. Thus, if a motor nerve be irritated, there is muscular contraction, in consequence of the stimulus reaching the muscular substance into activity, probably through the agency of the end-plates; but there will be at the same time a backward wave along the nerve to the motor centres in the cord or brain. It is doubtful whether the nerve-energy becomes weaker or gathers intensity as it passes along a nerve; but the balance of evidence is in favour of the view that the so-called "avalanche theory" of Pfleger, according to which the energy gathers intensity as it passes along, is incorrect.

Nerves  
classified.

**Classification of Nerves.**—Functionally, nerves may be classified into motor, sensory, vasomotor, secretory, and inhibitory. The original meaning attached to the term "motor" nerve was a nerve entirely composed of fibres by the excitation of which influences were conveyed to a muscle which caused the muscle to contract. As these influences passed outwards from a nerve-centre towards the periphery of the body they were also termed "efferent" nerves. On the other hand, nerves were found which, when stimulated, gave rise to sensations of pleasure or of pain, and these were called "sensory" nerves. Finally, it was shown that a third class of nerves were composed both of sensory and of motor fibres, and they were called "sensomotor" nerves. Sensory nerves were also subdivided into those of general and those of special sensibility. This was an artificial classification based on the fact that when a nerve of so-called special sensibility, such as the optic, was stimulated in any way the same kind of sensation followed. Thus stimulation of the optic nerve by cutting, pricking, pressure, or electricity is always followed by a luminous sensation. But the progress of research showed that when certain nerve-fibres were stimulated the result was not necessarily a muscular contraction; it might be contraction of a blood-vessel, modified secretion of a gland, or a diminution or arrest of some kind of nervous action. These facts demand another classification of nerves such as the following.

1. *Motor*, sometimes termed *efferent*, to muscles, exciting contraction.
  2. *Secretory*, to the cells of glands, causing secretion, possibly a particular kind of secretion.
  3. *Excitatory*, or *excitatory*, to the walls of blood-vessels, so as to cause contraction (constriction) or dilatation (excitation, or vascular dilation).
  4. *Inhibitory*, or *inhibitory*, to the walls of blood-vessels, so as to moderate or neutralize their action.
  5. *Electric*, so affecting a special organ as to call forth electrical discharges, as in electric fish, *Torpedo*, *Gymnastus*, *Malpighian*, &c.
- CENTRIFUGAL, OR EFFERENT, NERVES.**—These nerves convey influences from a nerve-centre.
1. *Sensory*, conveying influences from the periphery towards a nerve-centre.
  2. *Secretory*, conveying influences from a nerve-centre towards a gland.
  3. *Excitatory*, conveying influences from a nerve-centre towards a blood-vessel.
  4. *Inhibitory*, conveying influences from a nerve-centre towards a blood-vessel.
  5. *Electric*, conveying influences from a nerve-centre towards a special organ.
- CENTRIPETAL, OR AFFERENT, NERVES.**—These nerves convey influences from the periphery towards a nerve-centre.
1. *Sensory*, conveying influences from the periphery towards a nerve-centre.
  2. *Secretory*, conveying influences from a nerve-centre towards a gland.
  3. *Excitatory*, conveying influences from a nerve-centre towards a blood-vessel.
  4. *Inhibitory*, conveying influences from a nerve-centre towards a blood-vessel.
  5. *Electric*, conveying influences from a nerve-centre towards a special organ.

In addition there are nerve-fibres connecting nerve-cells in the great centres, to which no special functions can be attributed.

## 2.—TERMINAL ORGANS.

**Terminal Organs.** Although, as has been shown, a nerve may be stimulated in any part of its course, the stimulus is usually applied to a special structure adapted physiologically for the reception of the particular kind of stimulus. Such a special structure may be termed a

"terminal organ." For example, in the mechanism of vision (see *LYX*, vol. viii. p. 821 *sq.*) there are the retina or terminal organ, the optic nerve or conductor, and the brain or a portion of it, the recipient of the impression. The fibres of the optic nerve are not affected by light, but when they are mechanically or electrically irritated the result is a luminous sensation, because the action of the fibres of the optic nerve is to call forth in the brain the mechanism connected with luminous sensations. But light has a specific action on the retina, and in turn the activity of the retina stimulates the fibres of the optic nerve. The retina is therefore the terminal organ adapted for the reception of rays of light. In like manner, each sense has its appropriate terminal apparatus, and these are described under the headings of the various senses, **EYE, EAR, NOSE, TASTE, TOUCH.** To understand the true nature of nervous action it is necessary to be clear as to the functions of the terminal organs. They are liberating mechanisms. They do not transform the outer energy into the physiological energy, nervous action; but they call it into action. Thus light acting on the retina is not directly transformed into nervous energy, but it excites changes in the retina, which in turn produce activity of the optic nerve. The structure of each of these terminal organs need not be here described, but it may be stated that they all essentially consist of modified epithelium-cells, or what may be called "nerve-epithelium." In tracing their development throughout the animal kingdom it will be found that the simplest terminal organs are epithelium-cells on the surface of the body; but during evolutionary progress from lower to higher forms these cells become more and more modified and more and more protected by descending deeper into the structure of the animal, until we meet with the complicated organs of special sense in the higher animals. Another class of terminal organs is that comprehending the forms at the ends of motor nerves. Such are the end-plates found in muscle, and described in vol. i. pp. 861, 862. The different modes of nerve-termination may be here briefly classified.

Organ.	Terminal Organ.	Effect.
Skin (see TOUCH) ....	Tactile cells of Merkel, in the epidermis. Tactile corpuscles of Wagner and Meissner, in papillae of the skin. End-bells of Krause, in conjunctiva, penis, and clitoris. Pachian bodies, attached to nerves of hand or foot, or in the meninges. Corymbes of Grandry, found in hills of limbs. Network of fibres, as in cornea. Hair-cells, supported by arches of Corti, and connected with the tectorial membrane.	Touch, pressure, or temperature.
Ear (see vol. i. p. 861, and vol. vii. p. 820).	Hairs and cones of retina.....	Hearing.
Eye (see vol. i. p. 861, and vol. vii. p. 820).	Hairs and cones of retina.....	Vision.
Nose (see SNELL) ....	Hairs and olfactory cells.....	Smell.
Tongue (see TASTE) ..	Taste-bells and gustatory cells..	Taste.
Mucous (vol. i. p. 862)	Mucous end-plates of Doyere, Kuhn, Krause, Ranvier, &c.	Motion.
Glands .....	Nerve endings in secretory cells.—Pflüger and Knipf.	Secretion.
Electric organs (see vol. xii. pp. 619, 720).	Lamellae with free cilia-like processes.	Electric discharge.

## 3.—CENTRAL ORGANS.

### A.—General Physiology of Central Organs.

**General Structure.**—The central organs consist of a special kind of cells called "nerve-cells," of nerve-fibres, both medullated and non-medullated, and of a variety of connective tissue, termed "neuroglia." On cutting into any central nervous organ, such as

the spinal cord or brain, two kinds of nervous matter are seen, the white and the grey. The grey consists of nerve-cells, nerve-fibres, and neuroglia, whilst the white is composed chiefly of nerve-fibres with a small amount of neuroglia and no nerve-cells. Nerve cells vary much in form, as will be seen by referring to fig. 5. They may be spherical, ovoidal, or irregularly triangular. The cells of the spinal ganglia are usually rounded; those of the sympathetic more angular; those of the spinal cord multipolar; that is, having many processes or poles connected with them; those of the cerebrum triangular or pyramidal; and those of the cere-

FIG. 5.—Various forms of nerve-cells. a, multipolar, shapes from grey matter of spinal cord; b, d, bipolar, from of nerve-ganglia on posterior roots of spinal nerves; c, g, unipolar, from cerebellum; e shows indications of a process coming off at lower end; f, union of three multipolar cells in spinal cord; h, union of three tripolar cells in grey matter of cerebral hemispheres.

bellum flask-shaped, having processes at each end. A nerve-cell shows a large clear nucleus and a small nucleolus, whilst the cell-substance is very granular. Some observers think they have traced into the substance of the cell a fibrillated structure from the axis-cylinder of the nerve-fibre ending in the pole or process; but this is doubtful, and the appearance may be accounted for by the action of the reagent employed and by the great difficulty of correctly interpreting optical appearances under very high powers. The neuroglia is a delicate interstitial connective substance having small connective-tissue corpuscles imbedded in it.

**Chemical Constitution of Grey and White Matter.**—This is still imperfectly known, and throws almost no light on the functions of the central organs. By various chemical processes the following substances have been obtained from nervous matter: cerebrin, lecithin, albumin, neurokeratin, cholesterol and fats, creatin, xanthin, hypoxanthin, inositol, lactic acid, volatile fatty acids, salts, and water. The grey matter of the brain is distinguished chemically from the white chiefly by containing more water, albumin, lecithin, and lactic acid, and less cholesterol, fat, and protagon (Hermann). Doubtless many of these substances are derived from the disintegration of a more complex chemical substance not yet isolated in a pure state from nervous matter. Petrowsky gives the composition of grey and white matter as follows.

	Grey matter.	White matter.
Water .....	81.6	68.4
Solids .....	18.4	31.6
The solids consist of—		
Albumin and gelatin .....	55.4	27.7
Lecithin .....	17.2	9.0
Cholesterol and fats .....	18.7	51.3
Cerebrin .....	0.3	9.5
Substances soluble in ether .....	0.7	3.3
Salts .....	1.3	0.6

The salts found in nervous matter are similar to those in blood, and it would appear that phosphates, or rather combinations in which phosphorus exists, are the most prominent products of analysis. Thus about 40 per cent. of the salts consist of phosphates of soda and of potash—that is, the ash, on analysis, gives this result; but it must not be inferred that in nervous tissue phosphates of the alkalis exist to this amount, as there is every reason to think that phosphorous compounds, along with alkalis, exist in nervous matter, although not in the form usually called phosphates. The remarkably large amount of water, amounting to no less than from 70 to 80 per cent., indicates matter in a condition suitable for rapid molecular changes, on which, no doubt, the functions of the tissue depend.

*Excitability of Nerve* .....

the general phenomena manifested by such centres. These may be grouped under the heads of (1) reflex actions, (2) inhibitory actions, (3) accelerating actions, (4) vaso-motor actions, (5) secretory actions, (6) sensations, and (7) intellectual acts.

**Reflex Actions.**—Impressions made on sensory nerves are conveyed to nerve-centres, where they may or may not awaken consciousness. A sensation may be defined as the consciousness of an impression, and may or may not be followed by motion. Either motion may be voluntary, or it may be caused by direct stimulation of the motor nerve distributed to the muscles. The latter kind of action in the living body is not common. Usually motor nerves are acted on by the will or by emotional states; but it not unfrequently happens that physical stimuli occasion motion in an indirect manner, the impressions being carried along sensory nerves to a central organ, where changes are excited which result in a discharge of nervous energy along motor nerves to various muscles. Thus a frog in which the brain and medulla oblongata have been destroyed will draw up its limbs if the foot be pinched. Such actions, taking place without consciousness, are called "reflex actions," and the mechanism required for their performance may be thus described: (1) excitation of a sensory or afferent nerve, (2) excitation of an intermediate nervous or reflex centre, and (3) excitation of a motor or efferent nerve, which causes a muscular contraction. The diagram in fig. 6 shows the simplest mechanism; but it is rare to find the arrangements so simple, and the mechanism may become more complex (see fig. 7) either by the existence of a number of cells or groups of cells in the nerve-centre, or by the existence of numerous afferent or efferent nerves. The essence of a reflex action is the transmutation by means of the

FIG. 6.—Simple reflex action; 1, sensory surface; 2, muscle; a, sensory nerve; b, nerve-cell; c, motor nerve. The arrows indicate the direction in which the influence travels.

FIG. 7.—Double reflex action, or action in which two or more nerve-cells are involved; 1, 2, as in fig. 6; a, motor nerve; b, c, nerve cells.

irritable protoplasm of a nerve-cell of afferent into efferent impulses (Foster). The following is a brief summary of the leading facts relating to reflex action.

(a) The initial excitation may occur both in nerves of general sensibility and in those of the special senses; but certain nerves more easily excite reflex actions than others. Thus when light falls on the retina there is contraction of the pupil, the afferent nerve in this case being the optic (see vol. viii. p. 321 sq.).

(b) A reflex movement may occur whether we excite a sensory nerve at its commencement or at some point in its course, but in the latter case the action is less intense than in the former.

(c) Grey matter containing nerve-cells constitutes the chief portion of reflex centres, and groups of such reflex centres are frequently associated by internuncial fibres. The excitability is increased when these centres are severed from communication with psychical centres which preside over voluntary movements. Thus, after decapitation, reflex movements occur with greater intensity than in the injured animal; they are also more active during sleep. It is evident, therefore, that reflex actions may be restrained or hindered in their development by the action of higher centres. This is termed the "inhibition of reflex action."

(d) Reflex movements may occur in one muscle, or in many muscles or groups of muscles. One or more groups of muscles may be involved according to the strength of the stimulus applied to the sensory surface and the degree of excitability of the reflex centre at the time (see fig. 8). The facts are thus summarized by Pfliiger. Unilateral action: if in a decapitated frog we excite the skin of the hind foot 1, the excitation is transmitted from the centre a to the muscles 1 of the foot on the same side. Symmetrical action; if the excitation be more intense, it is transmitted to a centre on the

FIG. 8.—Complex reflex action; 1, 2, 3, 4, 5, sensory surface; a, b, c, d, e, sensory nerve; f, g, h, i, j, nerve-cells; k, l, m, n, o, motor nerve; 6, 7, 8, 9, 10, muscles. The arrows indicate the direction in which the influence travels.

opposite side *b*, and contractions may occur in the muscles of the hind limbs on both sides 1, 2. Irradiation; if the excitation be still increased in intensity, it affects higher centres *c*, *d*, and there may be contraction of the fore limbs 3, 4. General action; if the excitation be still further increased, it may pass to a still higher reflex centre *e*, and the result is general convulsions.

(7) Reflex centres may be so arranged in the body as to constitute a series in which those of the cerebrum govern or control others in the deeper ganglia of the brain, while these, in turn, have an influence over still lower centres in the spinal cord. This arrangement is termed the "superposition of reflexes" (see fig. 9).

(8) Stimulation of a sensory surface may simultaneously produce, by a reflex mechanism, movement, secretion, and consciousness. Thus a condition in the mouth may cause involuntary twitchings of the muscles, secretion of saliva, and a sensation (see fig. 10).

(9) Certain substances, in particular strychnin, increase reflex excitability, so that the slightest external stimulation of the sensory nerves of the skin is sufficient to cause severe convulsions. On the other hand, bromide of potassium, hydrate of chloral, and atropin diminish reflex excitability.

(10) In living animals only reflex action is seen, but stimuli applied at frequent intervals act the more quickly and powerfully the more rapidly they succeed each other. To produce the reflex change in the centre, therefore, a stimulus or addition of centrifugal excitations is required. When these reach a certain number the centre responds (Stirling).

(11) Reflex actions involve time. Thus the time between the stimulation and the movement can be measured, and, if we take into consideration the time occupied by the passage of the nerve-current along the nerves involved, and the latent period of muscular contraction, and subtract this from the total time, the remainder will represent the time occupied by the changes in the centre or the reflex-time. This has been found to be from 0.055 to 0.171 of a second. It is lengthened by cold and shortened by increasing the strength of the stimulus and by strychnin.

(12) In compound reflex acts the initial excitation may occur in psychical centres, as when the recollection of an odour causes nausea, or when a feeling of emulsi is followed by a yawn.

(13) Some reflex movements are the result of inherited peculiarities of structure, as the *s* made by a new-born child when it seizes the breast. Other reflex movements are acquired during life. Such are at first voluntary, but they become automatic by repetition.

Exam-  
ples of  
reflex  
action.

The following are some of the more common examples of reflex movements. Motion of the muscles in any part of the limbs or trunk under the influence of sensory impressions on the skin, such as tickling, pricking, &c.; shuddering from cold, shivering, caused by grating noises, &c.; contraction of the pupil under the influence of light on the retina; winking, from irritation of the sensory nerves of the conjunctiva; sneezing, from irritation of the Schneiderian membrane, or by a glaring light on the eye; spasm of the pharynx and coughing, from irritation of the larynx or trachea; laughing, caused by tickling the skin; the first respiration of the child at birth, from the impression of cold upon the nerves of the skin, and especially those of the chest; respiratory movements in the adult, from the impression caused by the afferent nerves of the lungs (sympathetic or vagus), by the presence of carbonic acid in the alveoli and passages, or in those of the general system; also, occasional modifications of the respiratory movements from impressions of cold, &c., on the surface of the body; sucking in infancy; deglutition or swallowing, with all the complicated movements then occurring in the tongue, fauces, larynx,

and gullet; vomiting, caused by irritation in stomach, or in fauces, or following nausea; forced contractions of the sphincter muscles of the anus, urinary bladder, and vagina, under local irritation; erection and emission under the influence of irritation of the nerves of the penis and other parts in the vicinity; rhythmic movements of lymphatic hearts in reptiles; rhythmic movements of the heart by the action of cardiac ganglia; peristaltic motions of the stomach and alimentary canal, in digestion and in defecation, &c., under the influence of impressions conveyed to the ganglia by the splanchnic and intestinal nerves; action of the bladder in expelling urine; expulsive action of the uterus in parturition; contractions and dilatations of the blood-vessels under the influence of the vaso-motor system of nerves; many obscure and complex morbid actions, such as palpitations of the heart, cramps in the limbs caused by irritation in the stomach or intestinal canal, fainting from concussion or from peculiar odours, dilatation of the pupil and grinding of the teeth from the irritation of worms, and the convulsive seizure sometimes occurring during feeding.

**Inhibitory and Accelerating Actions.**—As we have seen, stimulation of a nerve may cause a sensation, a reflex action, or the direct motor contraction of a muscle; but in some instances when the nerve and is stimulated movements may be arrested. This occurs where accelerative and apparently spontaneous or automatic actions are being restrained or inhibited by the activity of certain nerves. The most actions.

striking instance of inhibition is offered by the heart. The subject will be readily understood with the aid of fig. 11, which illustrates the innervation of the heart and blood-vessels and especially the inhibition and action of the depressor nerve.

It is well known that the heart of a warm-blooded animal ceases to beat almost immediately after removal from the body, but the heart of a cold-blooded animal, such as the frog, will beat for hours or even days, especially if it be supplied with deoxygenated blood. The rhythmic beat depends to some extent on the existence in the heart of ganglia or small nerve-centres (fig. 11, I, A, R). It is quite true, however, that rhythm may go on in a portion of the heart containing no ganglionic structure. Now the heart receives nerves from two sources, from the vagus or pneumogastric nerve and from fibres derived from the spinal cord through the sympathetic. If the vagus be cut and the lower end stimulated by feeble induction-shocks, the heart beats more slowly, and will probably be brought to a stand-still in a dilated condition. A strong stimulation of the vagus will invariably arrest the action of the heart, and the organ will be found dilated, or, as it is said, in a state of diastole. On removal of the stimulus the heart will soon resume its beats. It is clear that the vagus cannot be regarded as the motor nerve of the heart, because, if so, stimulation would have arrested the action of the heart in a state of contraction or systole. The question, then, is whether the fibres of the vagus possessing this remarkable power of inhibiting or restraining the action of the heart terminate in the muscular fibres, or in some intermediate structures, such as ganglia. The influence of various poisons has shed light on this question. A minute dose of atropin injected into the blood paralyzes this inhibitory action. After such a dose stimulation of the vagus is followed by no effect, and the heart beats as usual.

Again, in slight urari poisoning the inhibitory action of the vagus is still present; in the profounder stages it disappears, but even then inhibition may be obtained by applying the electrodes to the sinus. In order to explain this result, it has been suggested that what we may call the inhibitory fibres of the vagus terminate in an inhibitory mechanism (probably ganglionic in nature) within the heart itself, and that the urari, while in large doses it may paralyze the terminal fibres of the vagus, leaves this inhibitory mechanism intact and capable of being thrown into activity by a stimulus applied directly to the sinus. After atropin has been given inhibition cannot be brought about by stimulation either of the vagus fibres or of the sinus, or indeed of any part of the heart. Hence it is inferred that atropin, unlike urari, paralyzes this intrinsic inhibitory mechanism. After the application of muscarin or pilocarpin the heart stops beating, and remains in diastole in perfect stand-still. Its appearance is then exactly that of a heart inhibited by profound and lasting vagus stimulation. This effect is not hindered by urari. The application, however, of a small dose of atropin at once restores the beat. These facts are interpreted as meaning that muscarin (or pilocarpin) stimulates or excites the inhibitory apparatus spoken of above, which atropin paralyzes or places hors de combat" (Foster, *Text-Book of Physiology*, 4th ed., p. 156).

Thus physiologists are satisfied that, when the vagus is stimulated, currents of nerve-energy pass along its fibres to some of the intrinsic ganglia of the heart and inhibit or restrain these, so that the heart beats more slowly or is arrested altogether. But the centres in a heart may also be stimulated. After division of both vagi in a mammal, say a rabbit, the heart's beat may be quickened or accelerated by stimulation of the cervical spinal cord. Fibres having this power of accelerating the action of the heart have been traced from

FIG. 9.—Diagram illustrating the superposition of reflexes. 1, sensory nerve; 2, reflex centre; 3, motor nerve; 4, muscle; 5, sensory nerve; 6, reflex centre; 7, motor nerve; 8, muscle. The diagram shows how a single stimulus can trigger multiple reflexes through different pathways.

FIG. 10.—Diagram illustrating a complex reflex mechanism. The arrows indicate direction of currents. 1, sensory nerve; 2, reflex centre; 3, motor nerve; 4, muscle; 5, sensory nerve; 6, reflex centre; 7, motor nerve; 8, muscle. The diagram shows how a single stimulus can trigger multiple reflexes through different pathways.

FIG. 11.—The origins of pneumogastric and vaso-motor systems are in medulla, that of the sympathetic in upper portion of cord. The arrows indicate direction of nerve-currents. In the heart I represents a reflex centre, I an inhibitory centre, and A an accelerating centre.

the cervical spinal cord through the last cervical and first thoracic ganglia of the sympathetic. Stimulation of these *accelerator* nerves causes a quickening of the heart's beat, in which, however, "what is gained in rate is lost in force" (Foster). They are referred to here as showing another kind of nervous action, quite different from inhibition. Thus any nerve-centre concerned in reflex movements may have, by impulses reaching it from the periphery, its action inhibited or restrained or accelerated.

**Nerve and Blood-vessels.** *Influence of Nerves on Blood-Vessels.*—If the sympathetic nerve be divided in the neck, there is a dilatation of the vessels and an increase of temperature on the same side; but irritation by weak induction-currents of the cephalic end will cause the vessels to contract and the temperature to fall. In the sympathetic, therefore, there are nerve-fibres which influence the contractile coats of the blood-vessels. These fibres, called "vaso-motor," originate from a vaso-motor centre in the medulla oblongata between the point of the calamus scriptorius and the lower border of the corpora quadrigemina, in the floor of the fourth ventricle. From this chief vaso-motor centre nervous influences emanate which tend to keep the smaller vessels in a more or less contracted condition. If it be injured, paralysed, or destroyed there is at once great dilatation of the vessels, more especially those in the abdominal cavity, and the blood collects in these dilated vessels. This of course diminishes the arterial pressure in the larger vessels. Consequently, by observations on blood-pressure, it has been found possible to study the conditions of vaso-motor action. By connecting a kymograph (a recording manometer) with a large vessel, say the carotid, observing for a time the mean blood-pressure, and afterwards injuring the supposed vaso-motor centre, Ludwig and his pupil Or-janikoff at once observed an enormous fall of blood-pressure, to be explained by the paralysis of the smaller and a consequent

the gland, whilst the third set directly affects the activity of the secreting cells. According to Heidenhain, in addition to the vascular nerves supplying a gland there are secretory and trophic nerves. "Stimulation of secretory fibres leads to an increased flow of water, stimulation of the trophic to an increased secretion of specific substances and to an increased production of protoplasm" (Gamgee). The vaso-constrictor fibres of a gland are derived from the sympathetic, and the vaso-dilator and secretory from the cerebro-spinal system.

*Classification of Nerve-Centres.*—Although these are usually Nerve-centres classified anatomically, according to the organ in which they are centres situated, they may also be arranged according to their functions, as classified follows:—(1) *receptive* centres, to which influences arrive which feed, may excite sensations (in grey matter of brain), or some kind of activity not associated with consciousness (reflex centres of the cord and of the brain); (2) *psychical* centres, connected with sensation in the sense of conscious perception, emotion, volition, and intellectual acts (in the grey matter of the brain); (3) *discharging* centres, whence emanate influences which, according to structures at the other ends of the nerves connected with them, may cause movements, secretions, or changes in the calibre of vessels (in brain and spinal cord); (4) *inhibitory* centres, which inhibit, restrain, or arrest the actions of other centres.

#### B.—Special Physiology of Central Organs.

*General Physiological Anatomy.*—The central organs of the nervous system consist of ganglia or of what is called a "cerebro-spinal axis." The anatomy of the latter is described under AXATOMY, and some account of the gangliated cords in invertebrates and of the rudimentary nervous systems of the lower forms of vertebrates will be found under the articles CRUSTACEA, INSECTS, AMPHIBIA, BIRDS, ICHTHYOLOGY, &c. But, as one of the most effective ways of obtaining an intelligent conception of the complicated nervous system of man and of the higher animals is to trace its various forms in the scale of animal existence, and to observe the close correspondence between complexity of structure and complexity of function, a short introductory review of its comparative anatomy, from the physiological side, will here be given. In the first place, we find that the different forms of nervous systems may be divided into (a) those consisting of ganglia or chains of ganglia, as found throughout the invertebrates, and (b) those having a great axis of nervous matter forming a brain and spinal cord, the cerebro-spinal axis, as seen in vertebrates.

*Comparative View of Nervous System of Invertebrates.*—In the Nervous simplest forms of animals the protoplasmic cell is the seat of system sensation and of motion; but as the contractile or muscular of invertebrates become more marked sensation is relegated to the cells of the ectoderm, or outer layer of the body. As portions of this sensory layer become of higher value to the organism, their protection is accomplished by some of the sensory cells sinking into the body of the organism so as to be covered by less important structures. The portions, originally of the surface, thus differentiated and protected become ganglia, and processes pass from them on the one hand to cells in the periphery, so that they may still be influenced by external energies, and on the other to the contractile parts of the organism by which movements are accomplished. Still higher in the scale of life, the ganglia are connected by internuncial fibres, and the plan of the primitive nervous system bears a relation to the general type of structure of the animal. Thus in radiate animals the gangliated cords show a radiated arrangement, and when the animal form is bilateral and symmetrical the nervous arrangements are on the same type. It is also to be noted that the ganglion specially connected with the rudimentary organs of sense attains a size and importance proportionate to the development of the sense-organs. The nerves of the sense-organs are chiefly connected with the supra-oesophageal ganglion, which thus may be looked on as a rudimentary brain. When the body of the animal becomes more complicated by the development of similar segments (or metameres), we find that by a reduplication, as it were, of the sub-oesophageal ganglion a ventral chain of ganglia is formed, a pair of ganglia for each segment, the individual ganglia being connected by longitudinal commissures. Such an arrangement is seen in the ringed worms and in arthropods. The next step is a fusion of the ganglia into masses, according to the size and importance of the part of the body to be innervated (see vol. vi. p. 636, figs. 7 and 9).

No trace of a nervous system can be detected in *Protozoa*. The Scyphomedusoid forms of *Hydrozoa* show nerve-fibres and ganglion-cells (Schäfer) in the sub-umbrella and around the tentaculo-cysts (see vol. xii. p. 552, fig. 15), and in the Hydromedusoid forms the nerve-ganglion cells form a ring round the margin of the disk. In some of the *Actinozoa* (anemones, &c.) fusiform ganglionic cells united by nerve-fibres are said to exist (P. M. Duncan). In all the worms (*Vermes*) the most important central organs of the nervous system are placed in the anterior part of the body near the beginning of the alimentary canal. If they have a distinct head the nervous organ is in it and supplies branches to the sense-organs. From thence nerve-trunks radiate to the periphery of the body, often in the form of two longitudinal trunks on the ventral surface. Frequently there is a nervous ring round the oesophagus. Nerve-centres have been found in all the *Platyhelminthes*, *Rotatoria*, and *Bryozoa*. The *Ascidacea* and *Thaliacea* show a further advance. The central organ is placed on the oesophagus, surrounding it as a ring, from which nerves radiate forwards and

backwards. Often six strands of nerve run forwards, whilst a dorsal and a ventral trunk pass backwards. The size of these trunks depends on the length of the body. The cephalic ganglion is bilateral and is largely developed. In the *Hirudinea* and *Annulida* the cerebral ganglia are connected by commissures with a ventral cord, which, in turn, shows individual ganglia connected by commissures. Each ganglion consists of two equal portions with a transverse commissure, and in the higher forms they are so close as to form almost a single cord. It is also evident that the cerebral ganglia are composed of several ganglia fused together, and acquire functional importance as the sense-organs are more highly developed. In the *Echinodermata* the nervous system consists of a number of trunks placed ventrally and having a radial arrangement. Each of these trunks corresponds to the ventral ganglionic chain of the *Annulata*.

In the *Arthropoda* the nervous system consists of two bands thickened in the middle, connected with an optical apparatus (the nervous ring lies above the floor of the oral cavity, between the oesophagus and the lips of the ossicles of the masticatory apparatus. From this ring lateral branches issue which accompany the branches of the ambulacral vessels. In *Holothuroida* (sea-cucumbers) the nervous ring lies in front and near the mouth, and is thicker than the five nerves which it gives off, thus differing from the *Asteroida* and *Echinoida*. The nervous system of the *Arthropoda* resembles that of the *Annulida*. There is a large ganglion above the oesophagus, the cerebral ganglion, united to a ventral ganglion by two commissures so as to form a nervous ring. From the ventral ganglion a series of ganglia united by commissures extends along the ventral surface of the body. The increased size of the cerebrum is the most striking characteristic, and no doubt bears a relation to the higher degree of development of the sense-organs, more especially those of sight. In some *Crustacea* the optic nerves arise from distinct lobes. As pointed out by Gegenbauer, when the optic organs are reduced or lost the cerebrum becomes so small as to be represented by nothing but a commissure. In the individuals having a large portion of the body composed of similar metameres the ganglia are regular in size, appearing in pairs. On the other hand, in the *Thoracostraca* (crustaceans) the metameres are fused into larger masses so as to form a cephalo-thorax. The metameres are small, distinct, and more or less regular, the ganglia are also distinct and in pairs. In the *Protrachata* (Peripatus) the nervous system is simpler, and consists of the double ventral cord having no ganglia or swellings on it, distributed through it. In the *Myriapoda* there is a with ganglia corresponding to the metameres. In the *Arachnida* the ventral ganglia are often reduced in number and fused. They are characterized by the close connexion between the cerebral ganglia and the ventral cord, owing to the extreme shortness of the commissures (Gegenbauer). In the *Scorpiones* the nervous system is richly segmented, and remarkable for the large size of the ganglion giving off the pedal nerves. The spiders have a single large ganglion in the cephalo-thorax, no doubt consisting of several ganglia. In the *Acarina* (mites) the cerebral ganglion is extremely small, and the other ganglia are fused so as to form one single mass, giving off nerves all round. These minute animals show a remarkable degree of concentration of the nervous system. In *Insecta* (see fig. 12) the ventral cord traverses the whole length of the body, the ganglia being at equal distances, and all united by commissures. This condition is well seen in the larval condition, and is like the permanent state of the *Myriapoda*. When the insect passes into the adult condition changes occur, consisting essentially of the fusion of

and in most cases does not unite with the rest of the ventral cord. It shows hemispheres and a complicated structure. The first ganglion of the ventral cord supplies the organs of the mouth; the three succeeding send nerves to the appendages, feet, and wings; the remaining ganglia are small, except the last, which supplies the generative organs. There is great variety among the *Insecta* in the number of ganglia in the ventral cord, but coalescence always indicates a higher type of structure. The nervous system of the *Brachyopoda* is formed of masses of ganglia near the oesophagus. From these nerve-fibres pass to various parts of the body. There is an oesophageal ring, but the superior ganglion is very small, owing to the absence of higher sensory organs. In *Mollusca* (see vol. xvi. p. 637, fig. 1) the nervous system is divided into a superior ganglionic mass, which lies above the commencement of the oesophagus—the supra-oesophageal or cerebral ganglion—and a ventral mass which is connected with the other by commissures, and forms the inferior or pedal ganglia. They are both paired. The cerebral ganglion is connected with the sense-organs. Both the cerebral and the pedal ganglionic masses really consist of ganglia fused together. This is well shown in some of the lower forms, in which the pedal ganglia are divided, and form an arrangement like the ventral cord of the *Annulata*. The remarkable feature in the nervous system of *Mollusca* is the great development of the visceral ganglia and nerves supplying the heart, branchial apparatus, and generative organs (see vol. xvi. p. 643, figs. 17, 18; p. 644, figs. 20, 21, 22; p. 647, figs. 34, 35; p. 648, fig. 36). In the *Lamellibranchia* the cerebral ganglia are very small, owing to the absence of a head and its sense-organs. In some forms they are placed so much to the side as to be united by a long commissure. There are also two pedal ganglia, of a size proportional to the degree of development of the foot. The visceral ganglionic mass is often the largest. It lies behind the posterior adductor muscle, and is united by long commissures to the cerebral ganglion (vol. xvi. p. 693, fig. 144). The nervous system of the *Gastropoda* is remarkable for the large size of the cerebral ganglia. In the *Peropoda* the cerebral ganglia either retain their lateral position or approach the pedal ganglia, with which the visceral ganglia are also fused. The three ganglionic masses, cerebral, pedal, and visceral, are also represented in the *Cephalopoda*, but they are more differentiated by the thickening of the commissures. The ganglionic masses are of different size, and they are more differentiated than any other. It is possible to distinguish an outer grey layer, surrounding a white layer, composed of fibres (vol. xvi. p. 679, figs. 113, 114, 115). Lastly, in *Tunicata* the nervous system is dorsal, instead of ventral, as in other invertebrates. It is developed from the ectoderm, or outermost layer of the embryo, by an infolding so as to form at first a groove and afterwards a tube. In the *Ascidian* larva this nervous tube reaches throughout the length of the tail, and we have thus the remarkable condition of a dorsal-median nerve-cord, analogous to the cerebro-spinal system of vertebrates. Further, embryologists are of opinion that this rudimentary nervous system is the true central organ, although the greater portion of it

disappears by the atrophy of the tail in the passage from the larval to the adult state. (Gegenbauer.)

**Comparative View of Nervous System of Vertebrates.**—To understand the structure of the complicated central nervous system of vertebrates, and to appreciate the physiological importance of its various parts, it is necessary to trace its development in the embryo brates, and to note the various forms it presents from the lowest to the highest vertebrates. A consideration of the embryological and morphological aspects of the subject clears up many difficult problems which a study of the human nervous system, by far the most complicated physiological system in the body, fails to do, and in particular it gives an intelligent conception of its architecture, as seen both in simple and complex forms. The cerebro-spinal axis begins in the embryo as a tube of nervous matter produced by an infolding of the epiblast, or outermost embryonic layer. The tube widens at its anterior end, and, by constrictions in its wall, three primary cerebral vesicles are formed, which afterwards become the anterior, middle, and posterior parts of the brain. In the fully-developed condition the cavity of the tube remains as the central canal of the spinal cord and the ventricles of the brain, whilst the various parts of the brain and cord are formed by thickenings in its walls. The three cerebral vesicles have been called the fore-brain, the mid-brain, and the hind-brain. A protrusion from the anterior cerebral vesicle, at first single, but afterwards divided by a median cleft, becomes the rudiment of the cerebral hemispheres (*prosencephala*), the cavity remaining in the adult condition as the lateral ventricle on each side. From each cerebral vesicle another hollow process protrudes which constitutes the olfactory lobe (*rhinencephalon*). What remains of the cavity of the first vesicle becomes the third ventricle (*thalamencephalon*). In the

which become the *optic thalami*, a thin layer between the two constituting the *tænia semicircularis*, and the Y-shaped canal passing from the cavity between the thalami to the cavities in the cerebral hemispheres (lateral ventricles) is the *foramen of Monro*. The floor of the third ventricle is produced into a conical process, the *infundibulum*, at the blind end of which is the pituitary body, or *hypophysis cerebri*. The roof of this ventricle is very thin, and in connexion with it is developed the pineal gland, or *epiphysis cerebri*. Transverse fibres pass from the one corpus striatum to the others, constituting the *white commissure*, whilst the two optic thalami are connected by two *grey commissures*. In mammals the two cerebral hemispheres are connected by a large and important set of commissural fibres, forming the *corpus callosum*. In addition there are certain sets of longitudinal commissural fibres. Thus two sets of fibres arise from the floor of the third ventricle, arch upwards, and form the *anterior pillars of the fornix*. These are continued over the roof of the third ventricle and run backwards, constituting the *body of the fornix*. Behind this the bands diverge so as to form the *posterior pillars of the fornix*. In the higher vertebrates the upper lip of the foramen of Monro thickens, and becomes converted into a bundle of longitudinal fibres, which is continuous anteriorly with the anterior pillars of the fornix. These are continued back between the inner boundary of the cerebral hemisphere and the margin of the corpora striata and optic thalami, and project into the lateral ventricle, forming the *hippocampus major*. As in highly-formed brains the corpus callosum passes across considerably above the level of the fornix, a portion of the inner wall of the hemisphere on each side and a space between are intercepted. The two inner walls constitute the *septum lucidum*, and the space the cavity of

ventricles may be seen a ganglionic mass corresponding to corpus striatum and optic thalamus. The optic lobes are relatively large and show considerable differentiation of structure.

Mammals, even the lower orders, not only show a general enlargement of the cerebral hemispheres, but we find a commissure, the corpus callosum, uniting them. This commissure is of small size, and is confined to the fore part of the hemispheres in *Monotremata* (*Ornithorhynchus*, *Echidna*) and *Marsupialia* (kangaroos, &c.), and in some of the *Edentata* (ant-eaters; sloths, &c.), but it gradually extends farther and farther back as we ascend to the higher orders. The chief changes thus occur in the prosencephalon. In the lower orders of mammals the hemispheres are comparatively small and simple, and do not present any division into convolutions, and very little distinction even of lobes. The cerebral hemispheres gradually grow backwards, covering mid-brain, cerebellum, and medulla oblongata, as we find in the higher *Primates* (monkeys, apes, and man). There is also a general enlargement of the brain and of the cranial cavity. The development of a posterior lobe only takes place in the higher orders, and in these also the enlargement of the frontal lobes brings the front of the cerebrum more and more over the nasal cavities, causing a development of forehead. This also explains how the olfactory bulbs in more highly-formed brains are thrown below the frontal part of the hemispheres, instead of originating at their anterior borders. But the internal arrangements of the brain also become more complicated. The fornix, already described, establishes, by its longitudinal commissural fibres, a connexion between the anterior and posterior lobes of the cerebrum. In the *Monotremata* and *Marsupialia* the mid-brain retains a bifid form, constituting the optic lobes, or corpora bigemina, but in all higher animals each is divided into two by a transverse groove, forming the corpora quadrigemina, of which the anterior pair is the largest. As we ascend also, we find the surface of the brain becoming more and more convoluted (see figs. 19 and 20). This is the general fact; but whilst the convolutions are most numerous and deepest in the highest orders there is no regular gradation, as in each group there are very great variations in the degree of convolution (Allen Thomson). Thus in the *Monotremata* the *Echidna* has a more convoluted cerebrum than the *Ornithorhynchus*, whilst in the *Primates* the brains of the marmosets show a comparatively smooth non-convoluted surface, in striking contrast to the rich convolutions seen on the brains of the higher monkeys and of the apes. It is important to note that the cerebellum also becomes more and more complicated as we ascend from the lower to the higher groups. At first merely a lamina or band, as seen in fishes and amphibia, it is a centrally differentiated body in crocodiles. In birds there is an indication of a division into three portions, a central and two lateral, whilst the central is by far the larger, the two lateral being feebly developed. In *Monotremata* the central portion is larger than the lateral, but, whilst it is larger in *Marsupialia*, *Edentata*, and *Cheiroptera* (bats, &c.), it is clear that the lateral portions are increasing in size so as to make the disproportion less. But in *Carnivora* (felines, hyena, otter, bear, &c.) and in *Ungulata* (sheep, ox, camel, rhinoceros, horse) the lateral lobes, or hemispheres, of the cerebellum develop to a much greater size; and in most of the *Primates* they are much larger than the median portion, which is now called the worm or "vermiform process." As regards the development of the spinal cord continuous with the medulla oblongata, it need only be said that it does not show any marked peculiarities of structure in different animals. The grey matter from which nerve-fibres originate and in which they end is found in the centre of the cord, and it is most abundant in the regions associated with the development of limbs. The white matter is external, and, in the cords of the higher animals, can be differentiated by fissures into columns, the special functions of which will be hereafter considered. The size of the cord is influenced by the masses of nerves given off from it, so that it attains its greatest thickness and development in the four higher

divisions of the vertebrates possessing limbs. Thus, too, are formed cervical, dorsal, and lumbar enlargements, contrasting with the more uniform and ribbon-like form of the cord in fishes, although even in these there are special enlargements corresponding to the points of exit of important spinal nerves.

Size and Weight of Brain.—The gradual increase in the size of the brain, as compared with that of the body, which is observed as we rise in the animal scale, has some intimate proportional relation to a corresponding increase of the nervous and mental endowments. Information as to the size of the brain may be obtained by direct measurement of dimensions and weight; but as this is often difficult recourse may be had to the measurement of the capacity of the cranium, which contains, however, not only the brain but its accessories, such as membranes and blood-vessels. Details will be found in vol. I, p. 872.

After considering the measurements of several thousand skulls made by different observers, the late Dr Allen Thomson arrived at the conclusion that the cranial capacity is on the whole greater among the highly-civilized than among the savage races, and that there is even a very manifest difference to be found between persons of higher mental cultivation and acknowledged ability and those of the uneducated class and of inferior intellectual powers; and he states further that the amount of this difference may be from 5 to 7½ per cent. in persons of the same race, and about double that range in those of different races. Thus, the average adult brain of men in Britain being taken at 5 lb, or, more precisely, at 49½ oz. avoirdupois (women, about 44 to 44½ oz.), at an average specific gravity of 1040, would give a bulk of 82.5 cubic inches of brain-substance; 10 per cent. being deducted for loss by membranes, fluid, &c., the cranial capacity will be about 80 inches. Conversely, the weight of the brain may be calculated from the known cranial capacity. If, therefore, the brain of the uneducated class falls 2½ oz. below the average, whilst that of the more cultivated persons rises to the same amount above it, or to 52½ oz., we may regard these brain-sizes as corresponding with brain-bulks and cranial capacities of 73 and 87 cubic inches, and of 83 and 97 cubic inches respectively. The average brain-weight of an Australian aboriginal man is about 42 oz., corresponding to a brain-bulk of about 70 cubic inches, and a cranial capacity of about 75 cubic inches. There are, however, great variations in all races. Thus the brain of Cuvier, the great naturalist, weighed 65 oz. avoirdupois, corresponding to a brain-bulk of 108 cubic inches and a cranial capacity of 118 cubic inches; whilst, on the other hand, in Europeans the brain-weight has fallen as low as 32 oz., or a brain-bulk of 53 cubic inches and a cranial capacity of 63 cubic inches. The brains of the anthropoid apes—gorilla, chimpanzee, and orang—are all inferior to man in their dimensions. In the gorilla the brain does not attain more than a third of the weight of the average human brain, and in the chimpanzee and orang it does not reach a fourth, so that the ratio of brain-weight to body-weight in these animals may be as 1 to 100, whilst in man it ranges from 1 to 40 to 1 to 50. It is remarkable that in general among the largest animals of any group the brain does not reach a size proportionate to the greater magnitude of the other organs or of the whole body, so that in the smaller members of the same order a considerably greater proportional size of the brain is observed. Thus in the small marmosets the proportion of the brain-weight to the body-weight may be 1 to 20, or more than double the proportion in man. Similar facts are brought out in comparing the brains of cetaceans, pachyderms, dogs, &c., as shown in the following table.

Table of comparative sizes of Brain and Body.

Examples.	Brain-weight in oz. avoirdupois.	Internal cranial bulk in cub. in.	Whole weight of the body in lb.	Proportion of brain to body weight
Average European man	48 (3 lb)	65 to 88	140	1 to 46
Child at birth	12	22	7½	1 to 10
Chimpanzee	10	10	50	1 to 80
Marmoset	3	3	6 oz.	1 to 15
Middle-sized dog	8½	6	36	1 to 161
Small dog	2½	4½	7	1 to 45
Elephant	144 (9 lb)	300	6,720 (3 tons)	1 to 747
Pig	6	11	94	1 to 250
Whale	96 (6 lb)	650	134,400 (60 tons)	1 to 22,400
Porpoise	16	30	60	1 to 60

Although the proportion of brain-weight to body-weight in a male child at birth is 1 to 10, yet so rapidly does the brain continue to grow during the early period of childhood that by the age of three years it has attained more than three-fourths of its full size, by the age of seven years it has reached the proportion of nine-tenths, and after this, only by slow and small gradations, it attains the full size between the ages of twenty and twenty-five years. See PHYSIOLOGY.

From this survey of the comparative development of the brain comparative the following general conclusions can be drawn.

1. The first and essential portion of the cerebro-spinal axis is developed the portion forming the spinal cord and medulla oblongata, inasmuch as much as it is found throughout the whole range of vertebrate existence, and is connected with the reflex or automatic movements on which locomotion, respiration, and the circulation more or less depend, and with the simple sense of contact, or touch, or pressure. This portion is necessary to mere existence.

2. When higher senses are added, such as those of taste, smell, hearing, vision, portions of the anterior part of the cerebro-spinal axis are differentiated so as to form centres. The earliest and most important of these senses (next to touch) is vision, hence the high degree of development of the optic lobes even in the lowest forms; to these are added the optic thalami, which may be regarded as the centres of tactile sensations involving appreciation of differences of touch as to softness, smoothness, hardness, &c., requiring in the periphery special terminal organs. Special centres for hearing, taste, and smell are not differentiated. It is remarkable that the organs relating to the sense of smell are most anterior and most closely related with the prosencephalon, indicating, apparently, that this sense is one of the earliest in appearance, and probably, along with vision and touch, one of the most necessary to existence.

1 The large cranial bulk in this instance is connected with the enormous size of the roots of the cranial nerves.

2 Many of the facts of this paragraph as to size and weight of brain are derived from an unpublished lecture by the late Dr Allen Thomson.

the cord outwards. Again, section of a number of posterior roots is followed by loss of sensation of a part of the body on the same side, and, if the proximal ends of the divided roots—those next the cord—are irritated, painful sensations are excited. The posterior roots, therefore, contain sensory fibres, carrying impressions into the cord from the periphery. As we have seen, these roots are connected with the grey and white matter of the cord, and it is practically impossible to trace all their ramifications. Recourse must therefore be had to the evidence supplied by experiment (cutting, or by the Wallerian method, p. 26) and by pathological observation. In tracing the path of fibres, what may be called the "developmental method" has been pursued. It has been shown by Flerbeig that, "if the development of the cord be carefully observed, the medullary substance of the nerve-fibres is formed later along certain tracts of the white columns than in the rest of the white matter, so that in transverse sections of the cord these tracts are easily distinguishable by their more transparent grey appearance" (Quinn, vol. ii. p. 277). If the anterior columns be cut by an incision extending into the grey matter, leaving the posterior columns intact, voluntary movements disappear in the parts below the section. Again, section of the posterior columns and grey matter, leaving the anterior uninjured, enfeebles but does not destroy the power of voluntary movement below the section. Finally, section of an antero-lateral column on one side paralyzes voluntary motion on the same side. From these facts it is inferred (a) that the motor tracts passing from the brain to the periphery are in the antero-lateral columns, and (b) that the fibres forming these tracts are chiefly distributed to the same side of the body. These inferences are supported by pathological observation. In diseases where the anterior horns of grey matter are affected paralysis ensues, with complete stiffness of the limbs; and if, from hemorrhage, softening, or the pressure of tumours, the anterior portion of the cord be irritated there are spasmodic twitchings of muscles. Complete transverse section of the posterior columns does not abolish sensibility in the parts below; but there is a loss of the power of making co-ordinated movements. Section of the posterior columns and of the antero-lateral columns, leaving only the grey matter in the centre of the cord intact, does not abolish sensibility. Again, section of the antero-lateral columns and of the whole of the grey matter, leaving only the posterior columns uninjured, is followed by complete loss of sensibility in the parts beneath. The inference therefore is that sensory impressions pass through the grey matter. As already seen, many of the sensory fibres connected with the posterior roots descend in the grey matter. This explains some of the results obtained by Brown-Séquard, that hemi-section of the cord, involving the grey matter, enfeebled sensibility on the opposite side more and more as the section cut deeply into the grey matter; that a vertical section in the bottom of the posterior median fissure caused loss of sensibility on both sides; and that a lateral section, whilst it caused loss of sensibility (anæsthesia) on the opposite side, was followed by increase of sensibility (hyperæsthesia) on the same side, a curious fact, explained by Brown-Séquard as being due to irritation caused by paralysis of the vessels of the cord on the side of the section. It would appear also that tactile impressions travel, for a certain distance at all events, in the posterior columns. This has been inferred chiefly from the fact that in certain cases of paralysis involving the posterior columns, where the sensation of touch was absent, the patient could still feel a painful sensation, as when a needle was thrust into the skin; whilst in other cases, in which these columns were not affected, the converse held good. In the disease known as locomotor ataxia (see ATAXIA and PARALYSIS, vol. xviii. p. 392) the patient first passes through a period in which there are disorders of general sensibility, especially lancinating pains in the limbs and back. By and by there is unsteadiness of gait when the eyes are closed or in the dark, and to a large extent the patient loses the power of co-ordinating movement. Especially he is unable to judge of the position of the limbs without seeing them; in other words, the so-called muscular sense is enfeebled. At last there is a stage before death in which there is almost complete paralysis. A study of this disease has thrown much light on the physiology of the cord. It is known to be caused by a slow disorganization or sclerosis of the posterior root-zones, the posterior columns,—slowly passing on to affect the columns of Goll, the lateral columns, and the anterior grey horns, and ultimately involving the cord. The disordered sensations at an early stage, the staggering gait at a later, show that the posterior part of the cord has to do with the transmission of sensory impressions. The man staggers, not because he is paralysed as regards the power of movement, but because, in consequence of the sensory tracts being involved, he does not receive those peripheral impressions which excite or indirectly regulate all well-ordered movements of locomotion.

Spinal  
cord a  
reflex  
centre.

2. *As a Reflex Centre.*—The grey matter of the lower cervical, dorsal, and lumbar regions of the cord may be regarded as composed of reflex centres associated with the general movements of the body, whilst in the upper cervical region there are more differentiated centres corresponding to special actions. The initial excitation

may commence in any sensory nerve; the effect passes to the cord, and sets up changes in the nerve-cells of the grey matter, involving time, and resulting in the transmission outwards along motor fibres of impulses which excite particular groups of muscles. There is an exact co-ordination, with a given strength of stimulus, between certain areas of skin and certain groups of muscles, and thus movements may be so purpose-like as to simulate those of a conscious or voluntary character. Thus irritation near the anus of a decapitated frog will invariably cause movements of the limb towards the irritated point. The activity of reflex centres may be inhibited, as already shown, by higher centres, or possibly by certain kinds of sensory impressions reaching them directly from the periphery. Hence removal of these higher centres is followed by apparently increased reflex excitability. Strychnia and the alkaloids of opium increase it, whilst aconite, hydrocyanic acid, ether, chloral, and chloroform have an opposite effect. In certain pathological conditions also, as in tetanus, or in some slow progressive diseases of the cord, reflex excitability may be much increased. In tetanus the slightest touch, a movement of the bedclothes, the closing of a door, the vibration caused by a footstep, may throw the patient into severe and prolonged convulsions. The earlier formed ganglionic cells are those specially concerned in reflex acts.

*Special reflex centres* have been clearly made out in the cord. (1) *A Cilio-Special reflex centres* special centre, between the sixth cervical and third dorsal nerves, associated with the movements of the iris. The fibres controlling the radiating fibres of the iris, and found in the sympathetic, originate here (see EYE). Hence irritation of this region causes dilatation of the pupil, an effect not produced if the sympathetic fibres have been divided. (2) *Accelerating centres*, supplying fibres to the sympathetic which ultimately reach the heart, and irritation of these centres quickens the movements of that organ. (3) *Respiratory centres*. The movements of respiration, of a reflex character, involve the action of many thoracic and abdominal muscles. Section of the cord above the eighth dorsal paralyzes the abdominal muscles; above the first dorsal, the intercostals; above the fifth cervical, the serratus magnus and the pectorals; and above the sixth cervical, by paralyzing the phrenic, it arrests the action of the diaphragm. (4) *Genitourinary centres*. This is in the lumbar region. Irritation causes erection, &c.; destruction or disease is followed by loss of virile power. (5) *Defecatory and vesico-urinary centres*. These, connected with the movements of the sphincter and aid of the bladder, exist in the lower portion of the dorsal and upper portion of the lumbar regions. Disease or injury involving the centres causes involuntary evacuation of the bowel and complete paralysis of the bladder, with non-contraction of the bladder and complete retention of the urine, which constantly escapes in small quantity.

3. *As a Trophic Centre.*—The ganglion-cells in the anterior Cord as cornua undoubtedly have a trophic or nutritive influence upon trophic muscles. This has been determined chiefly on pathological evidence. centre. If the cells undergo atrophy or degenerative changes, the muscles, even though they may be kept periodically in a state of activity by galvanism, become soft and fatty changes take place. There is thus a correlation between the nutritive condition of muscle and nerve-centre, and influences affecting the one affect the other also.

It has been supposed that the cells in Clarke's vesicular column may form the centres in visceral innervation. They are bipolar, like those in the sympathetic, and not multipolar as in the rest of the cord, and the columns are absent in the lumbar and cervical enlargements. The cells are found where nerves come off that influence the viscera, and similar cells are found at the roots of the vagus in the medulla,—a nerve also much concerned in the innervation of viscera.

*Inhibition of Reflex Actions.*—The reflex actions of the spinal cord may be inhibited or restrained to a greater or less extent by tion of the action of centres in the encephalon, so that pure reflex actions reflex only occur after removal of the cerebrum, or during profound sleep, actions when the cerebrum is inactive. Thus a strong effort of the will may restrain from scratching an irritated part of the skin, whilst the same amount of irritation would certainly cause reflex movements if the will were in abeyance. Such power of voluntary control, however, is limited with respect to most reflex actions, whilst some reflex acts cannot be so influenced. Any movement that may be originated by the will may be inhibited or restrained to a certain extent when the movement is of a reflex character; but, if the movement be invariably involuntary, it can never be inhibited. Thus the ejaculation of semen cannot be voluntarily induced, whilst the reflex act once provoked cannot be arrested (Hermann). That these inhibitions of reflex actions of the cord depend on mechanisms in the brain is proved by the fact that removal of the brain is followed by an increase in the reflex excitability of the cord, and that even section of the cord permits of increased reflex excitability below the plane of section (Setschenoff). Further, after section of the spinal cord in the cervical region, irritation of the lower end arrests reflex movements dependent on reflex centres in the lower cervical, dorsal, and lumbar regions (McKendrick).

*Medulla Oblongata.*—This is the prolongation into the cranium Medulla of the spinal cord so as to unite it with the brain. Strictly speak- oblon- ing, the medulla spinalis and the medulla oblongata form one organ. gata. The columns of white matter of the cord undergo changes in form, structure, and relative position when they pass into the medulla (see vol. i. p. 870). Without again detailing the minute anatomy, it is necessary to show, as in the following table, the connexions of the cord and of the medulla with the rest of the brain.

Columns of the Spinal Cord.	Divided into	Continued in Medulla Oblongata as	Pass on to		
Antero-lateral column.	A. Pyramidal tract.	a. Lateral, or crossed, fibres from the posterior part of the lateral column as low as the third or fourth sacral nerves.	Decussate in anterior pyramids.	Cerebrum.	
		b. Anterior, or uncrossed, fibres from the dorsal region of the cord—columns of Turek, or columns of Lockhart Clarke.	Pass under pyramid on same side, and form longitudinal fibres of the reticularis alba in dorsal part of mesial area.	1. Posterior longitudinal bundle in pons. 2. Tract of the fillet.	Cerebrum. Corpora quadrigemina.
	B. Cerebellar tract.	c. Cerebellar tract, between lateral pyramidal tract and the outer surface of the cord as low as the second or third lumbar.	Restiform body.		Cerebellum.
	All the antero-lateral columns except A and B.	d. Principal tract of anterior column, that is, the antero-lateral column less the fibres in b. Not continued up—probably commissural from one side of cord to the other.	....	....	
Posterior column.		e. From anterior column.	Pass below olivary body to form part of restiform body. Sometimes called the "band of Solley"—not always present.	Cerebellum.	
		a. Posterior white column, or Goll's tract, from middle of dorsal region.	..	....	
		b. Posterior lateral column, between posterior median column and postero-lateral groove.	Posterior median column, becoming the funiculus gracilis, which, with the expansion called the clava, becomes the posterior pyramids.		Cerebrum.
		c. Funiculus of Rolando, between the posterior lateral column b and postero-lateral groove higher up.	Funiculus cuneatus, forming, with cerebellar tract from antero-lateral column, the restiform body.	Cerebellum.	

It is important to note the fact that each column of the cord, through the medulla, is thus connected both with the cerebrum and with the cerebellum. Development has shown that the fibres of the bundles which are first formed develop a medullary sheath at a time when the fibres of the later-formed bundles are non-medullated. "When the cord of a human embryo is examined at the end of the fifth month it will be found that the pyramidal fibres of the lateral columns, the fibres of the columns of Turek, and of the columns of Goll are non-medullated; while the fibres of the anterior and posterior root-zones and the cerebellar fibres of the lateral columns are medullated" (Ross). It would appear, therefore, that the latter are the more primitive structures, and that the former are super-added in the cords of the higher animals. The grey matter of the medulla is broken up by changes in the distribution of the white matter into nuclei or masses of nerve-cells, instead of having the crescentic form seen in the spinal cord. These nuclei are connected with the roots of important cranial nerves, and may be regarded as corresponding with the anterior horns of grey matter, with the posterior horns, and with the grey matter between these.

The following nuclei can be found:—(1) the *hypoglossal* nucleus, for the hypoglossal nerve, the motor nerve of the tongue; (2) a *common* nucleus, for a portion of the spinal accessory, vagus, and glossopharyngeal nerves; (3) the *principal* or *lower auditory* nucleus, for the auditory nerve; (4) nuclei for the *sixth* or *abducent* nerve, supplying the external rectus muscle of the eye; (5) nucleus for the *fourth* nerve, supplying the superior oblique muscle of the eye; (6) the *facial* nerve, the motor nerve of the face; (7) the *corpus dentatum* of the *olivary body*, not directly connected with the roots of nerves, but containing nerve-cells. Some fibres, both of the sensory and motor roots of the *fifth* nerve, originate also as far back as the medulla. The third, fourth, sixth, and hypoglossal nerves belong to the system of anterior motor nerves, related to the anterior cornua, whilst the spinal accessory, vagus, glossopharyngeal, and fifth belong to the "mixed lateral system,"—that is, they are related to the posterior cornua and intermediate grey matter.

Like the spinal cord, the medulla may be regarded as containing

tracts for sensory and motor transmission, and as constituting a series of reflex centres for special movements.

1. *As a Conductor of Motor and Sensory Impressions.*—Inasmuch Motor also, as such movements as those of the circulation, respiration, and vaso-motor action are necessary to life, destruction of the sensory medulla causes almost instant death. Motor fibres coming from transmission the brain above decussate in the anterior pyramids and then run down the lateral columns of the cord, issuing to the muscles by medulla of the anterior roots of the spinal nerves. Hence, whilst section of an antero-lateral column of the cord will cause paralysis of motion on the same side, section of an anterior pyramid above the decussation causes paralysis of motion on the *opposite* side. But fibres carrying sensory impressions also decussate in the grey matter at the bottom of the posterior median fissure of the cord. It follows, therefore, that disease, such as rupture of a vessel causing a clot in the brain, say in the left corpus striatum and left optic thalamus, causes paralysis both of motion and of sensation on the opposite side,—that is, in the case supposed, there would be right hemiplegia. The path of sensory impressions is probably in the grey matter but the precise course of sensory fibres has not been traced.

2. *As a Reflex Centre.*—Numerous special centres have been referred to the medulla oblongata.

(1) *Respiratory* centres, two in number, expiratory and inspiratory, connected with the roots of the pneumogastric nerves. Destruction at once causes cessation of respiratory movements. (2) *Vaso-motor* centre, regulating the calibre of the smaller blood-vessels throughout the body (see p. 30). (3) *Cardiac* centres, probably two in number—one accelerating, associated with the sympathetic; the other inhibitory, connected with the pneumogastric (see p. 29). (4) Centres for *deglutition*, associated with the sensory and motor nerves involved in this process (see NUTRITION, vol. xvii. p. 670). (5) Centre for *voice*, regulating to some extent the *larynx* and *phonation*. (6) Centre influencing *glycogenesis*, probably in the *liver*. (7) *Vaso-motor* centre on the blood-vessels of the liver (see NUTRITION, vol. xvii. p. 682). (8) Centre directly influencing *salivary secretion*, from which originate those fibres of the facial, forming the chorda tympani and lesser superficial petrosal, distributed to the salivary glands (see NUTRITION, vol. xvii. p. 672). (9) Centre for the *motor fibres supplying the face and muscles of mastication*. These exist in the facial for the muscles of the face and in the motor portion of the fifth for the muscles of mastication. Further, the medulla receives nervous influences from the higher centres, by which all the centres above enumerated may be more or less influenced.

*Pons Varolii.*—The pons Varolii is above and in front of the Pons medulla oblongata, and between the hemispheres of the cerebellum. It consists of fibres passing in two directions, viz., longitudinally, connecting the brain above with the medulla and cord below; and transversely, connecting the lateral hemispheres of the cerebellum, thus forming the middle peduncles of that organ.

Its general position and appearance are seen in fig. 23. Mixed up with these fibres are various nuclei of grey matter connected with the roots of cranial nerves. The most important of these nuclei are—(1) the nucleus of the facial nerve; (2) the motor nucleus of the fifth nerve; (3) the upper sensory nucleus of the fifth nerve; (4) the inner or chief nucleus of the auditory nerve; (5) the outer or superior nucleus of the auditory nerve; (6) the accessory nucleus of the auditory nerve; (7) the nucleus of the sixth nerve. It will be observed that several of these nerves are also connected with nuclei in the

Fig. 23.—Section of medulla oblongata and pons to show the course of fibres. a, superficial, and a', deep transverse fibres of pons; b, b', anterior pyramids ascending at b' through pons; c, c', olivary bodies; d, d', olivary fasciculus in pons; e, e', anterior columns of cord; f, inner part of right column joining anterior pyramid; g, outer part going to olivary fasciculus; h, lateral column of cord; i, the part which decussates at base of the pyramids; j, the part which joins the restiform body; m, that which forms the fasciculus teres; n, arciform fibres. 1 and 2, sensory and motor roots of the fifth nerve; 3, sixth nerve; 4, portio dura; 5, portio intermedia; 6, portio mollis of the seventh nerve; 7, glossopharyngeal; 8, pneumogastric; 9, spinal accessory; 10, hypoglossal nerve.

before its decussation in the pons. Usually in cases of paralysis striatum the paralysis of the face is on the same side as that of the limbs. In diseases of the pons loss of sensibility is a much more

rare result than loss of motion, and is always on the opposite side. According to Brown-Séquard, tactile, thermal, and painful impressions pass through the central part of the pons. The numerous centres in the pons are associated in complex reflex movements. Nothnagel has described it as a convulsive centre, because irritation caused severe cramps, but this was no doubt due to irritation of the motor strands passing through it.

**Cerebral Peduncles.**—These contain both sensory and motor fibres, and they establish a connexion between the cerebellum and the cerebrum, and also between the ganglia at the base,—corpora striata, optic thalami, and corpora quadrigemina on the one hand, and the pons and medulla on the other. Little is known of their functions except that they are conductors. Destruction of one peduncle causes the animal to move to the side opposite the lesion, describing a circle somewhat in the manner of a horse in a circus. Irritation may cause pain or movements of various groups of muscles.

**Basal Ganglia.**—As already shown in tracing the development of the cerebro-spinal system, the brain consists of a series of ganglia, in pairs, more or less overlapped by the cerebral hemispheres. These ganglia, termed the "basal ganglia," are usually held to include, from behind forwards, the corpora quadrigemina, the optic thalami, and the corpora striata; but in addition there are bodies meriting an equal amount of attention, inasmuch as they cannot be regarded as belonging to the cerebral hemispheres. These are the locus niger, the red nucleus of the tegmentum, and the corpora geniculata; but we have no knowledge of their functions. No doubt all these ganglia act along with the cerebral hemispheres, so that practically the whole mass forms one organ.

**Corpora Quadrigemina.**—These are two pairs of rounded bodies found above the Sylvian aqueduct, which passes between the third and fourth ventricles. They are situated behind the optic thalami, and are intimately related to the crura, and through these to the pons, medulla, and cord. Homologous with the optic lobes seen in the brain of the fish, frog, and bird (see figs. 17 and 18), and in marsupials and monotremes, their relative size to the mass of the encephalon is much less in the brain of man and of the higher animals. These bodies contain grey matter, covered by a thin stratum of white matter. The two posterior bodies are probably connected with the cerebellum by the superior peduncles of that organ; at all events these peduncles disappear under the base of the corpora quadrigemina. The two posterior bodies are also related to the crura cerebri by the prominences on the sides of the crura known as the inner geniculate bodies. Both anterior and posterior bodies, more especially the anterior, are connected with the optic tracts, and finally, the two anterior bodies unite with the optic thalami. (See fig. 24 below; also, plate XVIII., vol. i., fig. 1, g. g.) As shown by their anatomical connexions, the corpora quadrigemina are part of the mechanism of vision. Destruction causes immediate blindness. If, in a pigeon, the encephalon be removed with the exception of these bodies, the iris will still continue to contract on the influence of light. On then destroying one of these bodies, the iris is immobile, and the power of accommodation is lost. As the third cranial nerve (which is known to contain fibres controlling the circular fibres of the iris by which the pupil contracts, and the fibres governing the ciliary muscle by which the eye is accommodated or focused to varying distances) originates in the grey matter of the floor of the Sylvian aqueduct, close to the corpora quadrigemina, it is held that these bodies are the centres of the reflex movements of the iris and of the ciliary muscle. The corpora quadrigemina are also the first recipients of visual impressions. When light falls on the retina changes are there induced which stimulate the optic nerve-fibres, and these fibres carry impressions through the optic tracts to the corpora quadrigemina. What then occurs is matter of conjecture. Whether sensation is there excited, or whether to produce sensation it is necessary that the impulses be sent onwards to the cerebrum, or whether the impressions directly received from the retina may excite, through the corpora quadrigemina and adjacent ganglia, reflex movements (like those of the somnambulist, who may see so that his steps are taken rightly, but who may at the same time not see consciously), are all speculative questions. We know that these bodies are concerned in the movements of the iris and of the ciliary muscle, but their great proportionate size in lowly-formed brains indicates that this is probably a secondary function, and that they are largely concerned in the phenomena of consciousness of light and colour.

**Optic Thalami.**—These are two ganglionic masses placed behind the corpora striata and in front of the corpora quadrigemina. The internal surfaces are seen chiefly in the third ventricle, the upper surfaces in the same ventricle and the lateral ventricles (see vol. i. pp. 875, 876, figs. 74 and 75), whilst the external and under surface of each thalamus is united with other parts of the brain. The under surface receives fibres from the crus cerebri, whilst the upper surface is covered by fibres which diverge and pass between the thalamus and a mass of grey matter in the extra-ventricular portion of the corpus striatum (called lenticular nucleus), to form a white layer called the "internal capsule." From the internal capsule, which thus contains fibres from the optic thalamus, fibres

radiate outwards to the surface of the cerebral hemispheres. The under surface of the thalamus is connected with the tegmentum,—that is, with the layer of fibres forming the upper surface of the crus cerebri. They also receive fibres from the corpora quadrigemina, and according to some authorities from the superior peduncles of the cerebellum. The substance of the thalamus contains nerve-cells, scattered and also aggregated into two nuclear masses, but the relations of these to nerve-tracts have not been ascertained. It is important physiologically to notice that the thalami receive fibres from the back of the crura, and therefore are probably related to the posterior or sensory portion of the spinal cord.

There is still much uncertainty as to the functions of the optic thalami. The most commonly received opinion is that they are centres for the reception of peripheral impulses, which they may elaborate and transmit forwards to the corpora striata, or directly to the cerebral hemispheres. If the sensory impulses received by the optic thalami are sent to the corpora striata, and by these transmitted downwards and outwards through the crura cerebri, then reflex actions may occur in which the basal ganglia are the centres; but, if the impulses are sent up, in the first place, to the cerebral hemispheres, and by these transmitted down to the corpora striata, then the action must include the higher mechanism of the grey matter of the hemispheres. In the first case it is supposed by those who hold that consciousness is specially connected with the grey matter of the hemispheres that the action would be purely reflex and unconscious. Experiment has not thrown much light on this problem, owing to the deep-seated situation of these bodies rendering the results of operative interference untrustworthy. The little that has been done shows that injury to them does not cause paralysis of motion. Nor can it be said that such injuries cause loss of sensation, the only phenomenon observed being that the animal places its limbs in anomalous positions, and does not seem to be aware of having done so. Meynert is of opinion that the optic thalami fulfil the same functions as to tactile impressions—that is, impressions on the periphery of the body—that the corpora quadrigemina do for visual impressions—that is, impressions on the retina. In cases of apoplexy in which these bodies are involved there are always sensory disturbances on the side opposite the lesion. This would lead to the inference that the optic thalami are the sensory ganglia of the opposite sides of the body. They are not, however, the first ganglionic apparatus through which sensory impressions pass, but they probably co-ordinate in some way centripetal impulses before these are sent to the cerebral hemispheres, where they are correlated with feeling. Further, as the old name "optic thalami" indicates, these ganglia are concerned in some way in vision, because, if seriously injured, blindness, or at all events disturbance of vision, is one of the constant results. This favours the view that they are the "middlemen" between special sensory centres and the higher centres of the cerebrum.

**Corpora Striata.**—These ganglia, sometimes termed the "ganglia Corpora of the cerebral hemispheres," situated in front and on the outer striata side of the optic thalami, are seen in the lateral ventricles. (See vol. i. pp. 875, 876, figs. 74 and 75.) The greater part of each is imbedded in the white substance of the hemisphere (extra-ventricular portion), whilst the part seen in the floor of the lateral ventricle is called the intra-ventricular portion. Each of these contains a nucleus of grey matter, the *nucleus caudatus* in the intra-ventricular and the *nucleus lenticularis* in the extra-ventricular. The latter is separated internally from the intra-ventricular portion by a layer of white matter called the "internal capsule," whilst on the outer side there is another layer of white matter called the "external capsule," beyond which, again, is a lamina or web of grey matter, called the "claustrum," which separates the external capsule from the island of Reil. The internal capsule is of great importance inasmuch as it is continuous with the *crusta*, a portion of the crus cerebri, which, in turn, is a continuation of the pyramidal fibres of the medulla oblongata and the pons. Multipolar nerve-cells are found in the nucleus caudatus; in the claustrum the cells are small and spindle-shaped. Posteriorly, therefore, the corpus striatum is related by fibres with the optic thalamus; inferiorly, through the internal capsule, with the pyramidal portion of the medulla and cord; and externally and superiorly with the grey matter of the cerebrum. The corpus striatum is a centre for the co-ordination of centrifugal or motor impulses. It may be roused into activity by impressions reaching it directly from the optic thalamus, but probably it usually acts in obedience to impulses coming from the cerebral hemispheres. When a clot of blood is formed in, say, the right corpus striatum there is motor paralysis of the opposite side of the body, and, according to the size of the clot, the paralysis may affect more or less completely the different groups of muscles. Destruction of the two bodies destroys voluntary movement, but the animal may move forwards as in running. Destruction of the nucleus caudatus renders movements of progression impossible, and the animal performs movements of rotation. Nothnagel by injecting a minute drop of a solution of chromic acid destroyed the nucleus lenticularis of a rabbit, with the result of throwing the animal into complete unconsciousness. He also states

that in the corpus striatum of the same animal there is a point, the *nodus cursorius*, the excitation of which caused the rabbit to rush forwards. This observation agrees with the statement of Magendie that, when he injured the corpora striata, the animal seemed to have an irresistible propulsion forwards. Ferrier states that when the corpora striata were stimulated by an interrupted current convulsive movements of the opposite side of the body took

FIG. 24.—Three pairs of cerebellar peduncles (from Sappey, after Hirschfeld and Leveillé. Quain). On the left the three cerebellar peduncles have been cut short; on the right side the hemisphere has been cut obliquely to show its connection with the superior and inferior peduncles. 1, median groove of fourth ventricle; 2, the same groove at the place where the auditory stria emerges from it to cross the floor of the ventricle; 3, inferior peduncle or restiform body; 4, funiculus gracilis; 5, 5, superior peduncles, on the right the dissection shows the superior and inferior peduncles crossing each other as they pass into the white substance of cerebellum; 6, 6, fillets at the side of crura cerebri; 7, lateral grooves of crura cerebri; 8, corpora quadrigemina.

place; and when the current was powerful the side of the body opposite to the side of the brain stimulated was forcibly drawn into an arch.

Peduncles of cerebellum.

**Cerebellum.**—In connexion with the physiology of this organ it is important to note its connections with the rest of the cerebro-spinal axis. It has three peduncles: (1) the superior peduncles (see fig. 24)—*crura ad cerebrum*, or *processes ad testes*—together with the valve of Vieussens, connect the cerebellum to the cerebrum; (2) the inferior peduncles, or *crura ad medullam*, are the superior extremities of the restiform bodies; (3) the middle peduncles, or *crura ad pontem*, much the largest, are the lateral extremities of the transverse fibres of the pons Varolii. They act as commissural fibres for the hemispheres of the cerebellum. All these peduncles pass into the interior of the cerebellum at its base. In the interior of the organ, where the peduncles enter, we find a nucleus of grey matter, the *corpus dentatum*. The cortical substance consists of two layers.—an outer *molecular* layer, consisting of a delicate matrix containing a few round cells and fibres, and an inner or *granular* layer, containing granules or nucleated corpuscles closely packed together. The corpuscles are from  $\frac{1}{100}$ th to  $\frac{1}{200}$ th of an inch in diameter, and are mixed with a network of delicate nerve-fibres. At the junction of the granular layer with the molecular layer there are peculiar large cells called "Purkinje's cells." They are flask-shaped and about  $\frac{1}{100}$ th to  $\frac{1}{200}$ th of an inch in diameter, and the long process is directed towards the surface of the cerebellum (see fig. 25). The white centre of each lamina consists of delicate nerve-fibres, the terminations of which have not been satisfactorily made out. Probably they end in the plexus of nerve-fibres in the granular layer, or in the processes of Purkinje's cells. On comparing the section of cerebrum (fig. 23) with that of cerebellum (fig. 25) the contrast is striking. The structure of cerebellum is more like that of the retina (vol. i. p. 882, fig. 78) than of any other nerve-centre.

**Results of Experiments.**—The cerebellum is insensible to mechanical excitations. Puncture causes no indications of pain, but there may be twisting of the head to the side. Ferrier states that Faradaic

irritation causes movements of the eyeballs and other movements indicative of vertigo. Section of the middle peduncle on one side causes the animal to roll rapidly round its longitudinal axis, the rotation being towards the side operated on.

If the cerebellum be removed gradually by successive slices—an operation easily done in a pigeon—there is a progressive effect on locomotive actions. On taking away only the upper layer there is some weakness and a hesitation in gait. When the sections have reached the middle of the organ the animal staggers much, and assists itself by its wings in walking. The sections being continued further, it is no longer able to preserve its equilibrium without the assistance of its wings and tail; it attempts to fly or walk resemble the fruitless efforts of a nestling, and the slightest touch knocks it over. At last, when the whole cerebellum is removed, it cannot support itself even with the aid of its wings and tail; it makes violent efforts to rise, but only rolls up and down; then, fatigued with struggling, it remains for a few seconds at rest on its back or abdomen, and then again commences its vain struggles to rise and walk. Yet all the while sight and hearing are perfect. See fig. 26. It attempts to escape, and appears to have all its sensations perfect. The results contrast very strongly with those of removing the cerebral lobes. "Take two pigeons," says Longet; "from one remove completely the cerebral lobes, and from the other only half the cerebellum; the next day the first will be firm on its feet, the second will exhibit the unsteady and uncertain gait of drunkenness."

FIG. 26.—Pigeon from which the cerebellum has been removed.

There is thus a loss of the power of co-ordination, or of regulation of movement, without the loss of sensibility, and hence it has been assumed that in some way or other the cerebellum acts as the co-ordinator of movements.

**Co-ordination of Movement.**—The nervous mechanisms by which co-ordinations are co-ordinated—that is, adapted to specific ends—are not thoroughly understood, but a short description of what is of more known may be here given. Muscular movements may be either ment simple or complex. In winking, the movement of the eyelid is effected by two muscles, one bringing the lid down, the other raising it. But picking up a pen from the table, taking a dip of ink, and writing a few words involve a complicated set of movements of the muscles of the trunk, shoulder, arm, forearm, fingers, and thumb. To perform the movements with precision each muscle or group of muscles must act at the right time and to the proper amount. It is also clear that all this is accomplished automatically. We are not conscious of the requisite combinations; but it must be noted that many of these complicated movements are first acquired by conscious efforts, and that they become automatic only by repetition. Again, in walking, equilibrium is maintained by a delicate series of muscular adjustments. When we swing forward one leg and balance the body on the other many muscular movements occur, and with every change in the position of the centre of gravity in the body there are corresponding adjustments. It would appear that in all mechanisms of co-ordination the first part of the process is the transmission of sensory impressions from the periphery. These sensory impressions may be derived from the skin or muscles, and may be caused by variations of pressure arising in them. Thus, if we lift a heavy weight, as a large stone, by the right hand and raise it to the bend of the elbow we throw the body to the other side by the action of the muscles of that side, thus maintaining the equilibrium. We judge of the amount of force necessary to overcome an obstruction by the feeling of resistance we encounter. All the movements of the body, therefore, give rise to feelings of varying pressures, and these feelings regulate the amount or degree of muscular action necessary to maintain equilibrium, or to perform a requisite movement. This is at first a conscious experience, and a child has to pass through an education, often involving pain, before the nervous mechanisms become automatic and the movement is done without effort. But the ordinary sensory nerves, coming from skin and muscle, are not the only channels by which such guiding mechanisms are set in action. As one would expect, sensory impressions, such as those associated with sight and hearing, may be brought into play.

1. **Peripheral Impressions from Semicircular Canals.**—If the membranous portion of the horizontal semicircular canal in the sions internal ear of a pigeon be cut, the bird moves its head from side to side, and if one of the vertical canals be divided it moves the head sent-up and down. The effects may pass off in a few days if only one circular canal has been cut. If the canals on both sides be divided the canals movements are exaggerated and the condition becomes permanent. It will then be observed that the animal has lost the power of co-ordinating its movements. It can rest with only a twitching, perhaps, of the head, but if it attempt to fly or walk its movements are indefinite and irregular, like those of a dizzy person, or like those described as following injury to the cerebellum. The irregular movements do not arise from deafness, or noises in the ears, or partial paralysis, or from an uncontrollable impulse. Any strong sensory

FIG. 25.—Vertical section through cortex of cerebellum (Sappey). a, pia mater; b, external layer; c, layer of cells of Purkinje; d, inner or granular layer; e, medullary centre.

impression, such as holding the bird, supporting its beak, or holding a brilliant light before its eyes, will steady it, and it has been noticed that "it can, even without assistance, clean its feathers and scratch its head, its beak and foot being in these operations guided by contact with its own body." It has been supposed that the semicircular canals are concerned in the mechanism of equilibration, —a view urged chiefly by Mach and Crum-Brown. If a blindfolded man is seated on a horizontal rotating table, such as that used in a lighthouse for rotating or eclipsing the light, and the table is turned round, at first there is a sensation of movement in the same direction as that of the table; then this sensation fades away, until he has no sensation of movement, although the table may be rapidly rotating; finally, if the table be stopped without a jerk there is first a very short period in which there is no definite sensation, which is succeeded by a sense of rapid movement in the opposite direction, often accompanied by a feeling of nausea. Now it is evident that neither sight nor touch nor muscular sensations can give a sense of rotation in these circumstances, and yet it is possible to form a fairly accurate judgment of the angle through which the body has moved. It has been suggested that this is effected by the action of the semicircular canals. The membranous portions are surrounded by a fluid called the "endolymph," and are free to move through a short distance. Hence it has been supposed that rotations more or less rapid must cause variations of tension of the membranous portion. Thus, if the membranous part, especially the ampulla or dilated ends of the canals, lag behind when rotation in one direction takes place, the nerves ending in them will be subjected to a strain; by and by both membranous portions and surrounding parts will be moving with the same velocity, when there will be no strain and no sense of movement; and at last, when the rotatory movement is arrested, there will be a tendency on the part of the membranous portions, as they are floating in a fluid, to move on a little farther than the rest, and thus again produce a strain, causing a sensation of movement in the opposite direction. By similar reasoning it can be shown that if we take the peculiar position of the three canals into consideration any movement in space might be thus appreciated, and these appreciations enter into the judgment we form of the movements. According to this theory, the sense of equilibrium may be largely due to impressions derived from the position of the head, and, as muscular movements required for placing the body in definite positions are determined, as we have seen, by peripheral impressions, the irregular movements of the pigeon, after injury to these canals, may be accounted for. It is not improbable that in the bird, which from the structure of its extremities—feet and wings—can have no peripheral impressions so delicate as those derived from the papillae of the skin on the extremities of other animals, the sense of equilibrium is maintained chiefly by impressions from these canals, and this may account for the comparatively large size of these organs in birds and fishes. This is in correspondence also with the requirements of birds in the balancings of flight and of fishes in swimming. It is well known that disease or injury of these canals in the human being produces symptoms of vertigo and a diminution of the power of co-ordinated action, as in Menière's disease, showing that the canals, even in man, have similar functions to those in the bird.

**2. Peripheral Impressions from the Eye.**—Many movements are guided and controlled by the sense of vision. Simply blindfolding a bird usually makes it passive, and it will not attempt either to walk or to fly; the same effects to a less degree may be seen in a mammal; and a blindfolded man will stagger in his gait. The wonderfully accurate movements of the blind in walking are acquired by long and laborious effort, and are guided by the sensations of hearing, of touch, and of resistance. If the optic lobes of a frog be destroyed, its power of balancing itself is lost. There are thus at least three channels by which peripheral impressions pass to the centres and seem to guide or co-ordinate movement: (1) from the periphery, by nerves of ordinary sensibility arising in the skin, muscles, and viscera; (2) from the semicircular canals of the ear, by special nerve-fibres in the auditory nerve; (3) from the eye, by fibres of the optic nerve. How and where these skeins of sensitive impressions are gathered up and so arranged as to call forth the requisite movements can only be conjectured; but the cerebellum is the organ most likely to be concerned in such a mechanism. It is in organic connexion with many of the nerve-fibres conveying sensory impressions. By the restiform bodies it receives many of the sensory fibres of the spinal cord; the auditory nerve has roots intimately related to the cerebellum; and it is fair to assume that there are communications between the corpora quadrigemina and the cerebellum. Stimulation of the cerebellum causes movements of the eyeballs, and disease of the cerebellum is sometimes attended by blindness. How the cerebellum co-ordinates movement is quite unknown, and the difficulty in explaining its functions is not lessened by the clinical fact that extensive disease of this organ may exist without any appreciable sensory or motor disturbance. There is no evidence to support the view of the founders of phrenology that the cerebellum has to do with the sexual functions.

**Cerebral Hemispheres.**—As these have been fully described in vol.

i. p. 873, it is only necessary here to point out the anatomical facts that assist in explaining the functions of the organ. It is important to observe, first, the general arrangements of the fibres, and, secondly, the arrangement and structure of the grey matter. The white matter of the cerebrum consists of ascending or peduncular fibres, longitudinal or collateral fibres, and of transverse or commissural fibres.

(1.) **Peduncular Fibres.**—The crusta of the cerebral peduncles consists of bundles of longitudinal fibres derived mainly from the anterior pyramid of the medulla. The crust is quadrilateral in form, but in ascending to the hemispheres it becomes flattened from above downwards, so that the fibres spread out like a fan. The fan formed by these fibres is bent into the form of an incomplete hollow cone, the convex surface of which is directed upwards and inwards. Thus the fibres pass between the optic thalamus and the lenticular nucleus, forming the internal capsule. Higher up the fibres pursue their course beneath and to the outside of the thalamus and the caudate nucleus, and over the lenticular nucleus. "Still higher up the internal capsule has spread out from before backwards, while the anterior half forms an obtuse angle with the posterior. The angle where the halves meet is called the knee (fig. 27, K), while the divisions themselves are called the anterior (fig. 27, IK') and posterior segments of the internal capsule" (Ross). On emerging from the basal ganglia the fibres of the internal capsule radiate in all directions to reach the cortex of the brain, giving rise to the appearance called the "corona radiata." The following sets of fibres have been traced into connexion with the cerebrum.

FIG. 27.—(After Flechsig.) Horizontal section of brain of child nine months old, only a portion of the right side being shown. F, frontal; TS, temporo-sphenoidal; O, occipital lobes; op, optic lobes; In, island of Reil; Cl, claustrum; f, third frontal convolution; Th, optic thalamus; NC, caudate nucleus; LC, lenticular nucleus; IK, internal capsule; IK', anterior division; IK'', posterior division; ah, anterior horn; ph, posterior horn; gc, genu of corpus callosum; sp, splenium; mc, middle commissure; f, fornix; sl, septum lucidum.

(a) Sensory peduncular fibres, derived from the posterior root-zones and the columns of Goll. These are in connexion with the cerebellum; but, as shown by Meynert, Flechsig, and others, many pass up through the pons to reach the crus cerebri, occupying the posterior and external portion of the pyramidal tract. They do not appear to be connected with the optic thalamus and the lenticular nucleus, but pass between them to the cortex. (b) Fibres from the roots of the optic nerves, reaching the brain by what have been called the "optic radiations of Gratiolet." This bundle of fibres issues from the posterior and external border of the optic thalamus and is closely applied to the peduncular sensory tract in its passage through the internal capsule, and the fibres seem to be connected with the convolutions of the occipital lobe. It is important to note that at least one of the roots of the optic nerve (the internal) passes into the external geniculate body and thence into the anterior bodies of the corpora quadrigemina. Thus there is a path for the passage of impressions from the retina to the cortex of the brain. (c) Fibres from the olfactory lobes have been traced to a junction with the optic radiations of Gratiolet, and pass with them to the convolutions of the cortex of the occipital or temporo-sphenoidal lobe. (d) The pyramidal tract has already been traced through the spinal cord, medulla, and pons. It then goes on, as already seen, to form the internal capsule and the corona radiata, the fibres ending in the parietal lobe, the paracentral lobule, the superior extremities of the ascending frontal and parietal convolutions, probably the posterior extremity of the first frontal convolution, the posterior extremity of the third frontal, and the inferior extremities of the ascending frontal and parietal convolutions,—in short, in the convolutions forming the middle and parietal region of the surface of the cortex. (e) Fibres issuing from the external surface of the optic thalamus to join the internal capsule. These are distributed to the convolutions of the frontal and parietal lobes. (f) Fibres issuing from the external surface of the caudate nucleus, passing also into the corona radiata. (g) Fibres issuing from the superior and internal surface of the lenticular nucleus to join the ascending fibres of the internal capsule. (h) Fibres ascending from the superior peduncle of the cerebellum. Flechsig says that some of the fibres of the superior peduncle of the cerebellum of the opposite side pass uninterruptedly through the red nucleus and along the internal surface of the fibres of the pyramidal tract to

be distributed to the central convolutions of the cerebrum. (G) Fibres issuing from the corpus callosum and descending into the internal capsule. (A) Fibres of the external capsule which ascend from the crura and ultimately reach the cortex through the corona radiata.

In addition to the peduncular fibres above enumerated, all of which belong to what may be termed the system of the internal capsule and corona radiata, fibres from the fornix, tenia semicircularis, outer layer of septum lucidum, and the fillet of the crus also pass from below upwards to the cortex of the hemispheres (Ross).

(2.) *Longitudinal or Collateral Fibres.*—(a) Fibres running immediately below the surface of the cortex, and connecting the grey matter of adjacent convolutions. (b) Fibres in the gyrus fornicatus, a convolution immediately above the corpus callosum. It is said that bands of these fibres arise in the anterior perforated space and pass completely round the corpus callosum to end in the same perforated space, and that offsets of these fibres pass upwards and backwards to reach the summits of the secondary convolutions derived from the gyrus fornicatus near the longitudinal fissure. (c) Longitudinal fibres of the corpus callosum (nerves of Lancisi), connecting the anterior and posterior ends of the callosal convolution. (d) Longitudinal septal fibres, lying on the inner surface of the septum lucidum, and entering into the gyrus fornicatus. (e) The fasciculus uncinatus, passing across the bottom of the Sylvian fissure and connecting the convolutions of the frontal and temporo-sphenoidal lobes. (f) The longitudinal inferior fasciculus, connecting the convolutions of the occipital with those of the temporal lobe.

(3.) *Transverse or Commissural Fibres.*—(a) Many, if not all, of the fibres of the corpus callosum pass transversely from one side to the other and connect corresponding convolutions in the hemispheres. This is the generally accepted view; but Professor Hamilton of Aberdeen has recently stated that his preparations show that there is no such commissural system between convolutions, and that the fibres decussating in the corpus callosum are not continued to convolutions on the other side, but pass downwards. (b) The fibres of the anterior commissure wind backwards through the lenticular nuclei to reach the convolutions round the Sylvian fissure. (c) The fibres of the posterior commissure run through the optic thalami.

*Arrangement and Structure of Grey Matter.*—The grey matter in the medulla and basal ganglia has been already considered. A web or sheet of it is also thrown over the surface of the cerebrum, and forms the outer portion of all the convolutions. The cortical substance consists of cells and fibres imbedded in a matrix similar to the neuroglia of the spinal cord. It may be divided into five layers, which merge into each other by almost insensible gradations. The most external layer consists of delicate nerve-fibres, neuroglia, and a few small round cells destitute of processes (see fig. 28). Going deeper we find cells of a characteristic pyramidal form, the largest being in the deepest layer. Their bases are turned inwards, and their apices towards the surface of the convolution. Cleland states that fibres passing from the apices are continuous with the delicate fibres found on the very surface of the cortex. In the ascending frontal convolutions Betz and Mierzejewski have found pyramidal cells two or three times larger than those of other regions of the cortex, and these have been termed "giant-cells." All the pyramidal cells, no doubt, anastomose by their processes, and give origin to the nerve-fibres of the white substance, but it is rarely possible to trace the fibres from cell to cell. A consideration of these anatomical facts, along with those mentioned in connexion with the comparative anatomy of the brain, shows that the cerebral hemispheres are in intimate connexion by fibres with all the other portions of the cerebro-spinal system. Further, they are not only intricate in structure themselves, but the commissural sets of fibres indicate that there is harmony of function between one

FIG. 28.—(After Meynert.) Vertical section of a furrow of third cerebral convolution of man. 1, layer of scattered small cortical corpuscles; 2, layer of close-set small pyramidal corpuscles; 3, layer of large pyramidal cortical corpuscles; 4, layer of small close-set irregular-shaped corpuscles; 5, layer of fusiform corpuscles (like those in the claustrum); 6, medullary lamina.

1 In preparing the foregoing sketch of the fibres of the cerebrum the writer is much indebted to Ross, *Diseases of the Nervous System*.

determining the function of so complicated an apparatus recourse must be had to the evidence (1) of development, (2) of comparative anatomy, (3) of human anatomy, (4) of the observed effects of disease before and after death, and (5) of experiment. Facts have already been collected from the first three of these fields of inquiry, all tending to show that the grey matter of the hemisphere is associated with the manifestation of intelligence in its various forms. The phenomena of disease support the same conclusion. Diseases producing slow changes in the layer of grey matter on the cortex are invariably associated with mental disturbance, such as melancholia, mania, or dementia. If the grey matter be suddenly injured or submitted to compression, as by a blow causing fracture and depression of a portion of the skull, or the effusion of fluid consequent on inflammation, unconsciousness is a certain result. So long as the pressure continues there is no consciousness; if it be removed, consciousness may soon return. On the other hand, if the disease affect the white matter of the central portions or the ganglia at the base, there may be paralysis or convulsions without consciousness being affected. All the facts, therefore, of pathology relating to the brain indicate that the grey matter on the surface of the hemispheres is the organ of consciousness and of all mental operations. This statement is now an axiom of medical science, and the basis of the rational treatment of the insane and of all maladies of the central nervous organs.

Two methods of experiment upon the cerebrum have usually been followed, and both have yielded important results.

(a.) *Removal.*—Flourens and the older observers were aware of the fact that as successive slices of grey matter are removed from the surface of the cerebrum an animal becomes more dull and stupid, until at last all indications of perception and volition disappear. A pigeon in this condition (see fig. 29), if carefully fed, may live for many months; to quote from Dalton—

FIG. 29.—Pigeon, in which the cerebrum has been injured or removed.

"The effect of this mutilation is simply to plunge the animal into a state of profound stupor, in which it is almost entirely inattentive to surrounding objects. The bird remains sitting motionless upon his perch or standing upon the ground, with the eyes closed and the head sunk between the shoulders. The plumage is smooth and glossy, but is uniformly expanded by a kind of erection of the feathers, so that the body appears somewhat puffed out, and stretches its neck, perhaps shakes its bill once or twice, or smooths down the feathers upon its shoulders, and then relapses into its former apathetic condition."

Similar observations have also been made on reptiles and mammals, but the latter survive the operation for a comparatively short time. In watching such an animal it is difficult to divest one's mind of the belief that it still feels and sees and hears. It may be observed that it rarely makes movements unless stimulated from without. Thus it may remain motionless for many hours; but if pushed, or gently touched, it moves. As remarked by Prof. M. Foster—

"No image, either pleasant or terrible, whether of food or of an enemy, produces any effect on it, other than that of an object reflecting more or less light. And, though the plaintive character of the cry which it gives forth when pinched suggests to the observer the existence of passion, it is probable that is a wrong interpretation of a vocal action; the cry appears plaintive, simply because, in consequence of the completeness of the reflex nervous machinery and the absence of the usual restraints, it is prolonged. The animal is able to execute all its ordinary bodily movements, but in its performance nothing is ever seen to indicate the retention of an educated intelligence."

(b.) *Electrical Stimulation of Surface of Brain.*—It is remarkable that, although many of the early workers in cerebral physiology stimulated the surface of the brain by electric currents, they observed no effect, and therefore Magendie, Matteucci, Longet, brain-Weber, Budge, Schiff, and others taught that irritation of the surface of the hemispheres called forth no muscular movements; and it was generally accepted that the grey matter on the cortex of the brain was entirely concerned in the phenomena of sensation, volition, and intellectual action. During the Franco-German war in 1870 Hitzig had occasion to apply galvanism to a portion of the exposed brain of a wounded soldier, and he observed contractions of the muscles of the eyeball. When peace was restored, experiments were made on the lower animals by Hitzig and Fritsch, in which a portion of exposed brain was irritated by a continuous current, and it was observed that the phenomena took place on opening and closing the current. By these experiments the German observers discovered that, when certain areas of grey matter were stimulated, contractions of certain muscles occurred, and they were thus able to map out areas for groups of muscles. Immediately afterwards the research was taken up by Professor David Ferrier of King's College, London, who, using a Faradaic instead of a continuous current, greatly extended the field of inquiry, and obtained many important results, which are not only

of value in cerebral physiology but have been successfully applied to the diagnosis of various diseases of the nervous system. The motor areas as determined by Ferrier in the monkey are shown in fig. 30. Dr Ferrier has also indicated the corresponding motor areas in man by carefully comparing the convolutions with those of the monkey.<sup>1</sup> An inspection of the figures shows that the areas which, when stimulated, give rise to definite movements are distributed only over a part of the cortex. As stimulation gives rise to no movements over other regions of the brain, these have been assumed to be connected with psychical states, such as sensation, volition, &c. Much controversy has arisen as to the real

**FIG. 23.**—A. Left hemisphere; B. Right. Upper surface of head of *Pterodroma*. The numbers indicate: 1, lateral edge of opposite leg as in walking; 2, upper movements of thigh, leg, and foot, with slanted movement of trunk; 3, movements of tail; 4, retraction and elevation of opposite fore limb; 5, extension forward of opposite arm and hand, as if to reach or touch something in front; 6, e. g., d. i. ritual and combined movements of fingers and wrists, ending in elevation of fist; 7, inspiration and flexion of forearm, by which the hand is raised towards the mouth; 8, action of expiration, by which the angle of the mouth is retracted and elevated; 9, closure of bill of breast and upper lip, with degree of lower lip, as to expose the rasping tooth on the opposite side; 10, opening of mouth with protrusion of tongue; 11, closing of bill with retraction of tongue; 12, retraction of angle of mouth; 13, eye opened widely, pupils dilated, head and eyes turn toward opposite leg; 14, 15, eyelids closing to opposite leg; 16, generally retracting; 17, action retraction of opposite ear; 18, sub-ocular contraction; 19, small nodding motion of jawbone. (Continued.)

nature of the so-called "motor areas." It has been clearly ascertained that the effects are not due to diffusion of the electric currents influencing other parts of the brain. That there is to some extent such diffusion between the electrodes there can be no doubt, but the exact correspondence between the area stimulated and the movements produced, and the fact that shifting the electrodes a very short distance to one side or another is followed by different results, show that the effect is somehow owing to changes excited by the electric current in that particular area of grey matter. Hitzig, Ferrier, and others have also found that removal of the layer of grey matter of a "motor centre" is followed by enfeeblement of the movements assigned to the area, but in the course of a few days the paralytic symptoms disappear. The latter effect cannot be due to the corresponding centre on the opposite side taking up the work "as subsequent destruction of the latter produced the usual paralysis on the side opposite to the lesion, but did not cause a repetition of the paralysis on the side opposed to the first lesion" (Carville and Durt). It would appear, therefore, that after destruction of a centre on one side some other part of the same hemisphere may take up the functions of the destroyed part. Goltz of Strasburg has removed large portions of the grey cortex (even to the extent of almost the whole of one hemisphere) by a jet of water so as to avoid hemorrhage, and still recovery of motor power took place after a time, although there remained "clumsiness in the execution of certain movements." His opinion is that the paralytic phenomena are caused by the injury exciting an inhibitory action on lower centres. This view, substantially that advocated for many years by Brown-Séquard does not explain why it is that gentle irritation of the centre by a weak Faradaic current calls forth movements of a definite character. The evidence, therefore, is strongly in favour of the view that there are definite motor areas of grey matter on the cortex,—that is, in ordinary circumstances these areas are intimately related to specific muscles or groups of muscles. It is quite possible, however, that each group of muscles does not depend on one area alone, but on several, whilst it is more intimately related to one than to the others. This would account also for the fact that movements of a group of muscles may be excited by stimulation of other areas than those mapped out by Ferrier and Hitzig. Recently areas associated with definite movements of the thorax, abdomen, and pelvis have been discovered by Horsley and Schäfer, and thus almost all the muscular mechanisms have been connected with some of the cerebral convolutions.

Ferrier has also attempted to differentiate sensory centres. On Sensory stimulating the angular gyrus he obtained movements of the eye centres. and associated movements of the head, and he regarded the phenomena as being "merely reflex movements on the excitation of subjective visual sensation." He then found that, "when the angular gyrus of the left hemisphere was destroyed, the animal was blind on the right eye soon after the operation, but recovered sight completely on the following day." On destroying the angular gyri of both hemispheres, an animal became permanently blind in both eyes. In neither case was there motor paralysis. By similar processes of thought and experiment he placed the auditory centre in the superior temporo-sphenoidal convolution, the centres of taste and smell at the extremity of the temporo-sphenoidal lobe, and that of touch in the gyrus uncinatus and hippocampus major. On the other hand, Goltz asserts that even after removal of a considerable part of the cortex the animal is not actually blind, but suffers from an imperfection of sight; and he states that he "can no more obtain distinct evidence of localization in reference to vision or other sensations than in reference to movements." Ferrier's view is supported by the observations of Munk, who finds that destruction of a considerable portion of the occipital lobes causes blindness. Munk has put forth the important distinction that there may be blindness in the sense of total deprivation of vision, and "psychical blindness," or the "inability to form an intelligent comprehension of the visual impressions received"; and he supports that the grey matter of the cortex over the occipital lobes has to do with the elaboration of simple visual impressions into perceptions. In like manner he concludes that other parts of the cortex may have to do with the elaboration of tactile, olfactory, gustatory, and auditory sensations. This is a likely hypothesis, and not very dissimilar to what has been held for many years, the only novelty being that there is localization in these actions. At present the question cannot be regarded as settled; but it may be stated generally that the posterior portion of the brain has to do chiefly with the reception of sensory impressions, and the middle and lateral regions with the transmission outwards of motor impulses. But there still remains the anterior portion. Electrical irritation of the pre-frontal region of the cortex in the monkey causes no motor reaction. Complete destruction causes no paralysis of motion and no sensory disturbance. Dr Ferrier states:—

"The survival or destruction by the cauterization of the antero-frontal lobes is not followed by any definite physiological results. The animals retain their appetites and instincts, and are capable of exhibiting emotional feeling. The sensory faculties—sight, hearing, touch, taste, and smell—remain unimpaired. The powers of voluntary motion are retained in their integrity, and there is little to indicate the presence of such an extensive lesion or a removal of so large a part of the brain. And yet, notwithstanding this apparent absence of physiological symptoms, I could perceive a very decided alteration in the animal's manner and behaviour, though it is difficult to state in precise terms the nature of the change. The animals operated on were selected on account of their intelligent character. After the operation, though they might seem to one who had not compared their present with the past fairly up to the average of monkey intelligence, they had undergone a considerable psychological alteration. Instead of, as before, being actively interested in their surroundings, and curiously peeping into all that came within the field of their observation, they remained apathetic or dull, or dozed off to sleep, responding only to sensations or impressions of the moment, or varying their listlessness with restless and purposeless wanderings to and fro. While not actually deprived of intelligence, they had lost to all appearance the faculty of attentive and intelligent observation" (*Functions of the Brain*, 1st ed., p. 221).

Thus the frontal lobes appear to have to do with cognition and intellectual action. If so, the grey matter on the surface of the brain may be mapped out into three great areas—an area concerned in cognitions and volitions in front, a motor or ideo-motor area in the middle, and a sensory area behind. These distinctions are no doubt arbitrary to a considerable extent; but, if they are retained as the expressions of a working hypothesis, they are of service. Long ago, and prior to the researches above alluded to, Dr Hughlings Jackson pointed out that distast of certain areas of grey matter on the cortex of the hemispheres may occasion epileptiform convulsions, localized to particular groups of muscles. The theory of the localization of motor functions has been of great service in the diagnosis and prognosis of such diseases. As to the localization of the faculty of language in the third left frontal convolution, founded on pathological evidence, see *APHASIA*, vol. ii. p. 171.

The functions of the nervous system have now been described ; but they are so complicated and so closely related to each other as to make it no easy matter to form a conception of the system working as a whole. The progress of discovery naturally tends to differentiation, and probably to attach too much importance to one organ as compared with the others, so that we are in danger of losing sight of the solidarity of the whole nervous system. Probably every nervous action, however minute and evanescent, affects more or less the entire system, and thus there may be an under-current of nervous action streaming into and out of the nerve-centres, along with a perpetual series of interactions in the centres themselves, contributing to and accounting for the apparent continuity of conscious experience. Certain relations of one nerve-centre to the others are indicated in fig. 31. No one now doubts that consciousness has an anatomical substratum, but the great problem—consciousness of the relation between the two is as far from solution as in the past.

<sup>1</sup> For figures of human brain showing motor areas, see Foster's *Physiology*, 4th ed., Lgs. 86 and 87, pp. 627, 628.

days when little or nothing was known of the physiology of the nervous system. Consciousness upwards until now it takes refuge in a few thousand nerve-cells in a portion of the grey matter of the cortex of the brain. The ancients believed that the body participated in the feelings of the mind, and that, in a real sense, the heart might be torn by contending emotions. As science advanced, consciousness took refuge in the brain, first in the medulla and lastly in the cortex. But even supposing we are ultimately able to understand all the phenomena—chemical, physical, physiological—of this intricate ganglionic mechanism we shall be no nearer a solution of the problem of the connexion between the objective and subjective aspects of the phenomena. It is no solution to resolve a statement of the phenomena into mental terms or expressions and to be content with pure idealism; nor is it any better to resolve all the phenomena of mind into terms describing physical conditions, as in pure materialism. A philosophy that recognizes both sets of phenomena, mutually adjusted and ever interacting, may be no explanation; but at all events it is unpretentious, recognizes facts, and does not delude the mind by offering a solution which is no solution at all. But apart from the ultimate question there is the important one of whether physiologists are on the whole right in relegating sensation or consciousness entirely to the grey matter of the brain. The facts of comparative physiology are against such an exclusive notion, because we cannot deny consciousness to many animals having rudimentary nervous systems. As already said, research in anatomy and physiology and the observation of disease have driven physiologists to adopt the view that the brain is the organ of sensation. This is no doubt true in the sense that it ultimately receives all those nervous impressions that result in consciousness; but the parts transmitting the nervous impressions are in another sense as much concerned in the production of conscious states as the brain. This view of the matter, put forward by Professor John Cleland in 1870, has not received from psychologists the attention it deserves. His thesis is—“that the consciousness extends from its special seat so far as there is continuity of the impressed condition; that when an irritation is applied to a nerve-extremity in a finger or elsewhere the impression (or rather impressed condition) travels, as is generally understood, but exists for at least a moment along the whole length of the nerve, and that as soon as there is continuity of the impressed condition from finger to brain the consciousness is in connexion with the nerve and is directly aware of the irritation at the nerve-extremity” (*Evolution, Expression, and Sensation*, Glasgow, 1891, p. 106).

This view is quite consistent with all the facts of nervous physiology and presents fewer difficulties than the one generally held, which drives consciousness into the recesses of the nerve-cells in the cortex of the cerebral hemispheres. It appears to keep clear of the prevailing error in the philosophy of modern physiology,—that of regarding the body and even the nervous system as a vast series of almost independent organs, losing sight of the community of function and interdependence of parts, characteristic of the body of one of the higher animals.

#### CIRCULATION IN THE BRAIN.

A due supply of healthy arterial blood and the removal of venous blood are essential to cerebral activity. The brain is contained in an osseous case of which the total capacity is variable. The cerebral substance undergoes almost insignificant changes of volume even under a pressure of 180 mm. of mercury. The quantity of blood in the cranium may vary. In the rabbit not more than 1 per cent. of the total quantity of blood of the body (equal to about 5 per cent. of the total weight of the organ) is present at any one time in the brain, whereas in the kidney, by weight, the blood may amount to nearly 12 per cent., and in the liver to as much as nearly 30 per cent. (Foster). If a small round window be made in the cranium and a suitable piece of glass fitted into it, the veins of the pia mater may be observed to dilate or contract if inter-mediate pressure be made on the veins of the neck. There is

FIG. 31.—M., muscle; SK., skin; REF., reflex centre; INH., inhibitory centre; MOT., motor centre; G.S.E., centre of general sensation; S.S.E., centre of special sensation; S.E.Q., sense of equilibrium; VOL., volitional centre; EM., emotional centre; ID., ideational centre; EY., eye; EA., ear; TA., taste; SM., smell; V., vessel; G., gland; H&V., heart and vessels; EL.O., electric organs in some fishes. evidently, then, within the cranium some arrangement by which such variations become possible. This is probably accomplished by the anatomical arrangements of the sub-arachnoid spaces. These spaces, containing fluid, communicate freely with each other and with the space surrounding the spinal cord, so that when the quantity of blood increases in the cranium a corresponding quantity of fluid escapes into the spinal space, the walls of which are not inextensible like those of the cranium. In young children, before the fontanelles are closed, the variations of circulation and blood-pressure cause pulsations, of which there are two kinds—those coinciding with the ventricular systole, produced by the pulsation of the arteries at the base of the brain, and those coinciding with expiration. Pressure on the brain-substance beyond a limit leads to paralysis, unconsciousness, and death. The large sinuses probably assist in equalizing internal pressure, and, as inspiration favours the flow of blood from the sinuses, too great distension of these is also avoided. Vaso-motor nerves regulate the calibre of the arterioles of the brain, but we know nothing of the conditions affecting the nerves. Nor do we know how the waste-products of the brain are got rid of. There are no lymphatic vessels, but there are spaces around many of the vessels. These probably communicate with the cavities in the membrane containing the cerebro-spinal fluid, the value of which, as suggested by Foster, “depends in all probability more on its physiological properties as lymph than on its

FIG. 32.—Injected convolution of cerebrum (Duret). 1, 1, medullary arteries; 1', group of medullary arteries in fissure between two neighbouring convolutions; 1', arteries of system of arcuate fibres; 2, 2, 2, arteries of grey substance of cortex; a, large-meshed capillary network situated under pia mater; b, smaller-meshed capillary network situated in middle layers of cortex; c, somewhat larger network in internal layers adjoining white substance; d, capillary network of white substance.

mechanical properties as a mere fluid.” The grey matter is much more richly supplied with capillaries than the white matter, as seen in fig. 32.

#### CRANIAL NERVES.

The general anatomy of these nerves is described under ANATOMY, Cranial vol. i. p. 880 sq., and it remains only to enumerate their functions. nerves. Their deep roots have also been alluded to in treating of the medulla oblongata and the pons Varolii above.

1. The olfactory nerve. The nerve of smell (see SMELL).
2. The optic nerve. The nerve of sight (see EYE).
3. The oculo-motor or third nerve.—motor, supplying all the muscles of the eyeball except the superior oblique and external rectus; it also supplies the circular fibres of the iris and the ciliary muscle (see EYE).
4. The pathetic or fourth nerve.—motor, supplying the superior oblique muscle.
5. The trigeminal or fifth nerve. It has three branches: (A) The ophthalmic division of the fifth, or nerve of Willis, is sensory and supplies (a) the skin of the forehead, the eyebrow, the upper eyelid, the root and lobule of the nose; (b) the palpebral and ocular conjunctiva, the mucous membrane of the lacrymal passages, the frontal sinuses, the upper part of the nasal mucous membrane; (c) the cornea, the iris, the choroid, and the sclerotic; (d) the periosteum and to the intra-orbital muscles. It also influences the secretion of the lacrymal gland. It contains the fibres from the sympathetic governing the radiating fibres of the iris (see EYE), and also the vaso-motor fibres for the iris, choroid, and retina. It is associated with the otic ganglion. (B) The superior maxillary division of the fifth furnishes sensory branches to (a) the skin of the lower eyelid, ala of the nose, upper lip, and skin covering the malar bone; (b) the lary sinuses, the gums, the upper lip, and the Eustachian tube; the maxillate of the bones corresponding to its distribution; and (c) the teeth of the upper jaw. It furnishes filaments to the nasal and palatine glands, and prob-

ably to the glands of the velum palati. It contains vaso-motor fibres from the sympathetic for the vessels, and is associated with the sphenopalatine ganglion. (C) The inferior maxillary division of the fifth contains sensory branches to (a) the skin of the cheeks, temples, lower lip, chin, front part of the ear, and external auditory canal; (b) the mucous membrane of the cheeks, lips, gums, front part of the tongue, the mucous membrane of the tympanum, and the mastoid cells; (c) the peristomium of the lower jaw and temporal bones; (d) the teeth of the lower jaw; (e) the temporo-maxillary articulation; and (f) the muscles in the neighbourhood (muscular sensibility). It thus exercises an influence on taste, hearing, and secretion (see NUTRITION). It contains vaso-motor fibres for the blood-vessels. Its motor branch is distributed to the muscles of mastication; and it is related to two ganglia, the otic and the sub-maxillary.

6. The *zith nerve* is motor, and supplies the external rectus muscle of the eyeball only.

7. The *facial or seventh nerve* is purely motor, and supplies all the muscles of expression. It also contains secretory fibres influencing the action of the salivary glands (see NUTRITION). Some assert that the chorda tympani contains gustatory fibres, but the question has not been settled. Claude Bernard found that the facial contains vaso-motor fibres.

8. The *auditory or eighth nerve* is the nerve of hearing (see EAR). In addition to purely auditory filaments it contains fibres from the semicircular canals having to do with impressions of movement in space (see pp. 35, 39).

9. The *glossopharyngeal nerve* is sensory to (a) the mucous membrane of the posterior part of the tongue, the pillars of the fauces, the anterior face of the tympanum, the fenestra rotunda (see EAR), the mastoid cells, and the Eustachian tube along with the fifth. It probably supplies motor fibres to the muscles of the pharynx, but this is doubtful. Vulpian states that it contains vaso-dilator fibres for the vessels of the posterior third of the tongue.

10. The *pneumogastric or tenth nerve* has many complicated actions. (A) It is sensitive to (a) the mucous membrane of all the respiratory passages, including specially the larynx; (b) the heart; (c) a portion of the digestive tube, namely, the base of the tongue, the velum palati, the pharynx, œsophagus, stomach, and probably the duodenum; (d) it confers muscular sensibility on the muscles, to which it is distributed; (e) the mucous membrane of the biliary passages; (f) a part of the dura mater corresponding to the transverse and occipital sinuses; (g) the posterior part of the auditory canal. By the laryngeal branches it specially stimulates expiratory movements. (B) It is motor to (a) many of the muscles of the palate; (b) the constrictors of the pharynx; (c) the œsophagus; (d) the larynx by (a) the superior laryngeal to the cricothyroid muscle and a portion of the arytenoid, and by (b) the inferior or recurrent laryngeal to the rest of the muscles of the larynx; and (c) to the muscular fibres of the bronchial tubes. (C) It contains vaso-inhibitory fibres for the heart. In connexion with this organ the vagus also contains sensory fibres and fibres belonging to the depressor system. (D) It influences secretion in the stomach (see NUTRITION); but it is doubtful whether it has any action on the renal secretion. (E) It influences the production of glycogen in the liver (see NUTRITION).

11. The *spinal accessory* is a motor nerve supplying the sterno-cleido-mastoid muscle and the trapezius. It gives an important branch to the vagus (internal branch), which supplies all the motor fibres in that nerve distributed to the larynx, except those in the superior laryngeal supplying the crico-thyroid muscle, and also the motor fibres of the vagus sent to the pharynx. According to Heidenhain, it also supplies the vagus with the inhibitory cardiac fibres.

12. The *hypoglossal* is exclusively a motor nerve supplying the muscles of the tongue and also the sub-hyo muscles (see ANATOMY). It also contains vaso-motor filaments.

#### SPINAL NERVES.

The spinal cord gives origin in its course to thirty-one pairs of spinal nerves, each nerve having two roots, anterior and posterior, the latter being distinguished by its greater thickness and by the presence of an enlargement called a ganglion, in which are found numerous bi-polar cells. The anterior root is motor, the posterior sensory. The mixed nerve after junction of the roots contains (a) sensory fibres passing to the posterior roots; (b) motor fibres coming from the anterior roots; (c) sympathetic fibres, either vaso-motor or vaso-dilator.

#### SYMPATHETIC SYSTEM.

The fibres of the sympathetic system consist of two kinds—(1) of grey or gelatinous fibres, destitute of the white substance of Schwann; and (2) of medullated fibres similar to those met with in the cerebro-spinal centres. The grey fibres originate in the ganglia so prevalent in the sympathetic system, whilst the medullated fibres are believed to come from the cerebro-spinal system. The trunk of the great sympathetic nerve consists of a chain of swellings or ganglia, connected by intermediate cords of grey nerve-fibres, and extending nearly symmetrically on each side of the vertebral column, from the base of the cranium to the

coccyx. On this part of the nerve twenty-four ganglia are placed on each side. This great trunk, as it passes along the spine, is connected with the spinal nerves, the connecting fibres being of the two kinds already described. The grey fibres dominate in the sympathetic nerves, and the medullated in the cerebro-spinal; and these two elements are mixed in various proportions in both of the great divisions of the nervous system. At their lower extremities the main trunks of opposite sides generally unite in the middle line; and at the upper ends each trunk, after being connected with the eighth and ninth cranial nerves, extends to the cranium, passes into that cavity along with the internal carotid artery, and there, as well as in other situations, comes into connexion with all the remaining cranial nerves, except the olfactory, auditory, and optic. This conjunction may be effected directly, as with the fourth, sixth, and ninth nerves; or through a ganglion, as the ophthalmic, with the third and fifth; the sphenopalatine, otic, and sub-maxillary, with the fifth and seventh, or facial; the geniculate, with the seventh or facial; the jugular, with the glossopharyngeal; and with the vagus, through one of its own ganglia. On the fibres of the sympathetic distributed to the viscera numerous ganglia, or plexuses in which ganglia exist, are met with, and frequently there is a plexus following the course of each vessel.

As to the functions of the sympathetic, experiment has led to the following conclusions.

(a.) The *vaso-motor fibres of the head* are supplied by the cervical sympathetic, and originate in the cervical region of the cord, proceeding from it by the anterior roots of the lower cervical and upper dorsal nerves. The fibres supplying the radiating fibres of the iris also come from that region (see EYE).

(b.) The *vaso-motors of the upper limbs* and of the thorax come (a) from the inferior cervical and superior thoracic ganglia, and (b) from the cord, by communicating branches between the third and seventh dorsal vertebrae.

(c.) The *vaso-motor fibres of the lower limbs* come from the cord through the sciatic and crural nerves, whilst those of the pelvic organs are derived from the abdominal ganglia of the sympathetic.

(d.) The *vaso-motors of the abdominal viscera* exist chiefly in the splanchnic nerves; some fibres supplying the stomach appear to be derived from the pneumogastric.

(e.) The *splanchnic nerves* all arise in man from the thoracic ganglia of the sympathetic—the greater splanchnic from the fifth to the tenth ganglia, the lesser splanchnic from the tenth and eleventh, and the smallest splanchnic from the twelfth ganglion. The splanchnics supply the stomach, liver, spleen, pancreas, intestines, and kidneys. Division causes dilatation of vessels; irritation causes contraction of vessels, and appears also to arrest or inhibit peristaltic motions of the stomach and intestines. Probably they also contain secretory filaments. The functions of vaso-motor nerves have been already described.

A very complete bibliography of works relating to the nervous system will be found in the *Dictionnaire Encyclopédique des Sciences Médicales*, 2d ser., vol. p. 619. ### PART III.—PHYSIOLOGY OF PLANTS.

THE body of a plant, like that of an animal, consists of one or more structural units which are termed "cells," and in plants, as in animals, the cell consists essentially of an individualized mass of protoplasm.

The probable structure and chemical composition of protoplasm have been already considered. It need only be stated here that the protoplasmic cell-contents do not consist of pure protoplasm, but that the protoplasm contains imbedded in it particles of various substances which may be of the nature of food, or which may have been formed from food, or which are products of the metabolism of protoplasm; it is to the presence of these particles that

the granular appearance of protoplasm is largely due. Moreover, there is present in the protoplasm of the cell, in the vast majority of cases at least, a well-defined, highly-refractive, usually somewhat spherical body, also protoplasmic in nature, the nucleus.

The cell or cells constituting the body of a plant present, in most cases, the important peculiarity that the protoplasm is enclosed in a membrane termed the "cell-wall." This membrane does not consist of protoplasm, but of a substance, cellulose, belonging to the group of the carbohydrates, and having the formula  $\alpha\text{C}_6\text{H}_{10}\text{O}_5$ . All cell-walls do not, however, consist exclusively of this sub-

stance, though this is probably always the case at their first formation; but the cell-wall may undergo considerable modification during the life of the cell. It may, for example, undergo lignification; it then comes to consist largely of a substance termed "lignin," which is much richer in carbon than is cellulose; this takes place typically in those cells which form woody or sclerenchymatous tissue. Or it may undergo cuticularization, when it comes to consist largely of a substance termed "suberin" or "cutin," which, like lignin, is richer in carbon than cellulose. Or, again, it may become gummy or mucilaginous. These chemical differences are accompanied by differences in the physical properties of the cell-wall. A cellulose cell-wall is extensible, capable of swelling from taking up water into itself by imbibition, and is readily traversed by water. A lignified or cuticularized cell-wall is more rigid and less capable of swelling by imbibition; moreover, a cuticularized cell-wall is almost impermeable to water. A gummy or mucilaginous cell-wall is more extensible and more capable of swelling by imbibition.

Structure of cell.

The structure of the plant-cell is not the same at all periods of its life. When a cell is young the protoplasm occupies the whole of the cavity enclosed by the cell-wall. But in the course of growth the increase in bulk of the protoplasm is not nearly so great as the increase in surface of the cell-wall, so that in the mature cell the protoplasmic contents form merely a rather thin layer known as the *primordial utricle*, which lies in close contact with the internal surface of the cell-wall at all points. There thus comes to be a relatively large cavity in the cell, the *vacuole*, which is filled with a liquid, the *cell-sap*, consisting of water holding various substances, organic and inorganic, in solution. The structure of a mature living cell is then this: it consists of a cell-wall, lined with a layer of protoplasm, which encloses the vacuole, filled with cell-sap.

Function of cell.

The protoplasm of plants is endowed with all those fundamental properties which are possessed by that of animals. When a plant is unicellular these properties are all exhibited, so far as they are necessary to the maintenance of the organism, by its protoplasm; in other words, all the necessary vital functions are performed by the protoplasm of the single cell of which the plant consists. The performance of all the necessary vital functions by the protoplasm of one cell obtains also in the case of not a few multicellular plants,—in those, namely, in which all the cells are similar to each other in structure and contents. In the great majority of multicellular plants, however, the functions are distributed to a greater or a less extent; there is more or less complete physiological division of labour. In these plants the cells are not all similar in appearance, and their diversity is to be ascribed to their adaptation in different ways to the performance of particular functions. Further, the cells which have undergone modification in some particular direction for the performance of some particular function are grouped together in certain parts of the plant, and these parts are spoken of as "organs." Thus the roots of one of the higher plants are the organs for the absorption from the soil of water and substances in solution; the leaves are the organs for the absorption of gases from the air, and, in virtue of the green colouring-matter chlorophyll, which their cells contain, they are also the organs in which certain important constructive processes are carried on. But the extent to which physiological division of labour is carried out in plants is not nearly so considerable as it is in animals, and accordingly the protoplasm of the different cells of plants exhibits only in a very slight degree that specialization of structure which is so conspicuous in animals.

### Absorption.

1. *Absorption of Water and Substances in Solution.*—The bodies of plants, unlike those of the great majority of animals, do not contain any internal cavity into which the food may be taken as a preliminary to its being absorbed by the tissues. The materials of the food of plants are therefore taken up directly from without into the cells of the absorbent organs. The cells which are especially concerned in absorption are, in the higher and subaerial plants, the *root-hairs*,—thin-walled, unicellular, unbranched filaments which are developed from the epidermal cells some way behind the growing-point of the root; in the lower plants, and even in those of the higher plants which lie submerged, all the cells of the plant may take part in absorption. Since the food is directly absorbed by the cells, and since the cells all possess a cell-wall, the materials of the food must be taken up in solution. Salts and other substances are, as a matter of fact, taken up by the absorbent cells in the form of watery solutions. Substances which are soluble in water are dissolved in the water which is present in a greater or smaller proportion in all soils, and of those which are not soluble in water many are brought into solution by the acid sap which saturates the walls of the root-hairs. The actual process of absorption is an instance of diffusion through a membrane,—that is, of osmosis. Only such substances can be absorbed by a root-hair, for instance, as are capable of diffusing not only through the cell-wall but also through the protoplasmic primordial utricle. Further, only such substances can be absorbed by the root-hair as are present in larger proportion in the water to be absorbed than they are in the cell-sap of the root-hair; this inequality between the proportion of any substance in solution in the liquid on the one side and in that of a membrane on the other is a necessary condition of osmosis. Hence, in order that the absorption of any particular substance by the root-hairs may be continuous, it is necessary that the substance in question should not accumulate in the cell-sap; this accumulation is prevented either by the actual consumption (*i.e.*, chemical decomposition) of the substance in the cell or by the withdrawal of it to supply the needs of adjacent cells. In fact, so far as the process of absorption is concerned, the cell-sap of the internal cells of the root stands in the same relation to the cell-sap of the root-hairs as the cell-sap of the root-hairs does to the external liquid; and, as this relation exists between the successive internal layers of cells, there is set up a current of absorbed substances which travels from the surface towards the centre.

Absorption by root-hairs.

Osmosis.

It appears from the foregoing considerations that the amount of any particular salt absorbed in a given time depends upon (1) its diffusibility and (2) its consumption in the plant. Of these two conditions the second is the one which is of real physiological importance, and, if only the given time is sufficiently long, the first condition may be neglected. For instance, let us suppose that a plant is absorbing by its roots two salts—the one (*A*) being very diffusible, the other (*B*) much less diffusible—and that, whilst the former undergoes no change in the plant after absorption, the latter is at once decomposed. Now, if the time of observation is short, it may happen that the amount absorbed of the salt *A* will be found to be greater than that of the salt *B*; but, if the time be extended, the amount absorbed of the salt *B* will certainly be found to be greater than that of the salt *A*. The explanation is that the salt *A* would at first be absorbed very rapidly, on account of its high diffusibility; but the absorption of it would gradually diminish, in consequence of the accumulation of it in the cell-sap of the plant, until it ceased altogether. The absorption of the salt *B*, on the other hand,

Conditions of amount absorbed.

if less active at first than that of *A*, would be continuous, and thus, over a relatively long period of time, the amount of it absorbed would come to be much greater than that of *A*.

**specific absorbent capacity.** As a matter of fact, it has been ascertained that when different salts or other substances are presented to the root of a plant they are absorbed in different quantities. And further, it has been ascertained that the different salts are absorbed in different proportions by the roots of different plants; it is, in fact, upon this that the necessity for the "rotation of crops" depends. A striking illustration of this is afforded by a comparison of the amount of silica present in the ash of equal dry weights of gramineous and leguminous plants. According to Wolff—

100 parts meadow-hay contain	27.01	per cent. of silica.
" wheat-straw "	67.50	" "
" red clover "	2.57	" "
" pea-straw "	6.83	" "

The absorption of salts in certain proportions by a plant is the expression of what may be conveniently termed its "specific absorbent capacity." It must not be supposed that this term suggests that the roots possess any selective power by which they absorb this salt and reject that one, or by which this one is absorbed in larger proportion than that one. The question as to whether or not a particular substance will be absorbed is a purely physical one, dependent upon the relation between the molecules of the substance and the cell-wall and primordial utricle which they have to traverse, and in no degree dependent upon the usefulness or hurtfulness of the substance to the plant. The amount absorbed of any particular substance depends ultimately upon the activity with which the plant chemically alters the substance after absorption. To return to the illustration just given. The great difference between the amounts of silica present in the ash of gramineous and of leguminous plants respectively is the expression of the fact that the former are capable of withdrawing relatively large quantities of absorbed silica from the sphere of osmotic activity, and depositing it in the insoluble form in the tissues, whereas the latter can only do so to a comparatively small extent. The specific absorbent capacity of a plant is simply a manifestation of its specific metabolic properties.

**Law of absorption.** The amount of the various salts absorbed is not, however, exclusively dependent upon the specific absorbent capacity of the plant, for it is materially affected by the composition of the soil. The larger the quantity of any substance presented to the roots, the greater, other things being equal, will be the amount of it absorbed. This does not mean that substances can be absorbed by the roots in solutions of any degree of concentration. It appears that the root-hairs can only absorb very dilute solutions; but for the watery solution of any salt capable of being absorbed there is a certain degree of concentration at which the proportion of the amount of the salt absorbed to that of the water absorbed is the same as that of the solution. If the solution be more concentrated the proportion of water absorbed will be greater, if the solution be more dilute the proportion of salt absorbed will be greater. This is the general "law of absorption" determined by the experiments of De Saussure and of Wolff. It must, however, be borne in mind that, though the *proportion* of salt absorbed is larger in the case of a dilute than of a more concentrated solution, yet the *absolute quantity* of it absorbed from a more concentrated solution in a given time is greater than that absorbed from a dilute solution.

**Absorption of gases.** 2. *Absorption of Gases.*—An interchange of gases is constantly taking place between the plant and the medium in which it lives—in the case of terrestrial plants, between the plant and the air; in the case of aquatic plants, between

the plant and the water. When the plant is a simple one each of its cells is in direct relation with the external medium; when it is of complex structure there is usually some means provided by which the more internal cells are brought into relation with it, namely, a continuous system of intercellular spaces which communicate with the exterior in terrestrial plants by certain apertures termed "stomata," in the epidermis of the leaves and young stems, and by others termed "lenticels," in the cortical tissue of older stems and of roots.

The gases principally absorbed by plants are oxygen and carbon dioxide. The former is absorbed by every living cell, and at all times; the latter is absorbed exclusively by cells which contain chlorophyll, and by them only when exposed to light. In the more highly-organized plants the cells which contain chlorophyll are confined almost entirely to the leaves, so that the leaves may be regarded as the organs by which these plants absorb carbon-dioxide. It has been held that the stomata are of great importance in promoting the absorption of this gas by the leaves, but the experiments of Boussingault prove that this view is not well founded. He discovered, namely, that the upper surface of the leaves of various plants with which he experimented absorbed carbon dioxide more actively than the lower surface, although the upper surface had scarcely any stomata, whereas they were very numerous on the lower. The absorption of carbon dioxide by the leaves is directly effected by the superficial cells.

Gases, like solid substances, are only absorbed in solution by the cells of plants. They may be brought to the surface of the cell-wall already dissolved in water, as in the case of submerged plants, or they may be dissolved from the atmosphere by the sap which saturates the cell-wall, as in the case of land-plants; in either case they reach the interior of the cell in solution. When a gas has been taken up at the surface it diffuses throughout the cell-sap; and in the case of a gas like nitrogen, for instance, which is not chemically altered in the cell, the absorption of it will cease when the cell-sap has become saturated with it. If, however, the metabolism of the cell changes the chemical condition of a gas its absorption will be continuous. This accords with what has been said with regard to substances absorbed by the roots.

Another analogy exists between the absorption of gases and the absorption of substances in solution, namely, that, just as the root can only absorb a solution below a certain degree of concentration, so the leaf can only absorb a gas below a certain degree of pressure. Let us take in illustration the case of carbon dioxide. The pressure of the carbon dioxide in the air is very slight (0.04 per cent. by volume). It was first observed by Percival that an increase in the quantity of carbon dioxide in the air is favourable to the nutrition of green plants; De Saussure found that a considerable increase is prejudicial; and subsequently Godlewski showed that the optimum proportion is from 8 to 10 per cent.,—that is, that carbon dioxide is most readily absorbed by the plant when its pressure is about 200 times greater than in ordinary air. Boussingault found that when leaves are exposed to sunlight in an atmosphere of pure carbon dioxide at the ordinary pressure they cannot decompose it, but if the gas is at a low pressure (in his experiment 0.17 mm. of mercury) they can do so.

Besides oxygen and carbon dioxide other gases are also absorbed by plants, but to a small extent only. Nitrogen is absorbed in small quantities merely in virtue of its solubility and diffusibility; as mentioned above, it is not in any way acted upon by the cells after its absorption. It appears that ammonia may be absorbed from the air in the form of gas by the leaves, and that, when thus absorbed, it contributes to the nutrition of the plant. Other gases,

such as sulphur dioxide, sulphuretted hydrogen, and hydrochloric acid, which are occasionally present in the air as impurities, are absorbed by the leaves, as is shown by the pernicious effects which they produce.

#### Circulation.

Osmotic  
circula-  
tion.

It is obviously necessary, in multicellular plants in which certain cells only are in a position to absorb food-materials from without, that these food-materials should be conveyed from the absorbent cells to the remainder of the plant. In no plant is there any organ comparable to the heart of animals by means of which a distribution throughout the tissues of absorbed food-materials is effected. The distribution is accomplished by purely physical means, principally by osmosis. When the cell-sap of a cell becomes charged, by absorption from without or from neighbouring cells, with any substance, diffusion-currents are at once set up between this cell and any adjacent cells the cell-sap of which may contain the substance in question in smaller proportion, and these currents will persist until osmotic equilibrium, as far as this substance is concerned, is established. The diffusion-currents do not flow in any definite direction, but their course is determined simply by inequalities in the chemical composition of the cell-sap of the cells in different parts of the plant. Since in subaerial plants the roots are as a rule the only organs which absorb substances from the soil, and since the cell-sap of their cells is therefore relatively rich in absorbed food-materials, the general direction of the diffusion-currents is from the roots upwards into the stem and leaves.

In cellular plants—that is, in plants which possess no vascular tissue—the distribution of absorbed food-materials is effected solely by osmosis. Many of these plants are small, so that the distribution is effected from cell to cell with sufficient rapidity by this means. Those of them that are large have a very considerable absorbent surface, many of them being aquatic in habit, so that the absorbed substances have no great distance to travel. In vascular plants, more particularly in those which are subaerial in habit, the distribution of the water, holding substances in solution, which is absorbed by the roots is effected to a considerable extent by means of the vascular system. The forces by which the flow of liquid through the vascular tissue is maintained are the following. The first is the

Root-  
pressure.

*root-pressure.* It is a matter of common observation that, when the stems of vascular plants are cut across, particularly in the spring, an escape of water takes place from the surface of that portion of the stem which still remains connected with the root, an escape which may persist for some considerable time. It has been ascertained that this outflow of water takes place under considerable pressure; for instance, Hales observed, in the case of a Vine, that the pressure was sufficiently great to support a column of mercury  $32\frac{1}{2}$  inches in height. But the root-pressure not only manifests itself by causing a flow of water from the cut surfaces of stems, it also causes in many plants the exudation of drops of water at the free surface. Drops may commonly be seen on the surface of certain Fungi (*Pilobolus crystallinus*, *Penicillium glaucum*, *Merulius lacrimans*), which are exuded in consequence of the hydrostatic pressure set up in the plant by the active absorption effected by the organs (rhizoids) which here perform the functions of roots. Again, drops are frequently to be found on the margins and at the apices of the leaves, especially the younger ones, of many plants, such as Grasses, Aroids, Alchemillas, Saxifrages, &c. That the formation of these drops depends upon the forcing of water upwards through the vessels by the root-pressure is proved by the fact that, if the stem be cut off from the root and then placed with its cut end in water, no more drops will appear

on the leaves. The water thus forced into the vascular system is not pure water, but a watery solution of various substances, principally salts absorbed by the roots. It is therefore obvious that the root-pressure assists in the distribution of these substances throughout the plant.

In order to understand how the root-pressure is set up it will be necessary to give a brief description of the general structure of the root. It consists of a central fibro-vascular cylinder which is surrounded by several layers of parenchymatous cells, the most external of these layers being in contact with the epidermal layer, certain cells of which are developed into root-hairs. Water is absorbed by the root-hairs and passes from them by osmosis into the subjacent parenchymatous cells. It is obvious, however, that osmosis cannot take place between the cells of the innermost layer and the vessels, for the conditions of osmosis are not fulfilled, inasmuch as the vessels at first contain no liquid. The passage of water from the cells into the vessels can only take place by filtration. For this a certain pressure is necessary, and this pressure is set up by the absorbent activity of the root-hairs and of the parenchymatous cells. The system of cells absorbs large quantities of water, more indeed than the cells can contain, so that at length the resistance of the cell-walls is overcome at what is presumably the weakest point, and water filters into the cavities of the vessels of the wood. There it collects, and it may, under certain circumstances, fill the whole vascular system; then, since absorption is still going on at the surface of the roots, sufficient pressure is set up to cause that exudation of drops on the leaves to which allusion has been made, and, if the stem be cut across, to cause "bleeding" at the cut surface. From the foregoing account it is apparent that the root-pressure is the expression of the absorbent activity of the root-hairs.

But the vessels of the wood do not always contain water. Transpiration. Hales observed that, whereas a Vine will bleed freely if its stem be cut across in the month of April, no bleeding is observed if it be cut in July. And yet it cannot be doubted that the plant is absorbing water by its roots more actively in July than in April. The explanation of these facts is that, although in July the plant is absorbing water actively by its roots, yet it is losing so much in the form of vapour from its leaves that water does not accumulate in the cavities of the vessels. This loss of water in the form of vapour from the general surface of the plant exposed to the air is termed "transpiration." The parts of the plant which are more especially concerned in transpiration are the leaves. By their structure they are peculiarly adapted for this purpose. The tissue of a leaf is penetrated in all directions by intercellular spaces, which communicate directly with the external air by means of the stomata in the epidermis. In this way a very large surface of moist and thin cell-wall is brought into contact with the air, a condition most favourable to evaporation. Some idea of the activity of transpiration in a plant is afforded by the following determinations made by Hales. In the case of a Sunflower with a leaf-surface of 5616 square inches the amount of water transpired during twelve hours of daylight was 30 fluid oz. (a pint and a half); in the case of a Cabbage with 2736 square inches of leaf-surface the amount of water transpired in the same time was 25 fluid oz. The activity of transpiration is very much affected by external conditions,—the moister the air, the smaller will be the transpiration; and conversely, the drier the air and the higher the temperature, the greater will be the amount of water transpired. Light, too, has a remarkable influence: it has been ascertained by a great number of observers that transpiration is more active in light than in darkness. It seems probable that this is to be attributed largely to the influence of light upon the stomata. Each stoma is

usually bounded by two cells, termed "guard-cells," which are capable of so altering their form as to close or to open the aperture between them. The form of the guard-cells is dependent upon the amount of water which they contain. When they hold comparatively little water, and are flaccid, their adjacent free surfaces are straight and in contact with each other; the stoma is then closed. When, however, they contain so much water that their cell-walls are under considerable pressure from within—in a word, when the guard-cells are turgid—they curve so that their adjacent free surfaces are no longer in contact, but a space is left between them; the stoma is then open. It appears that the guard-cells become turgid under the influence of light; and it is probably to this open condition of the stomata that the greater transpiration of leaves when exposed to light is to be ascribed.

It is obvious that the effect of transpiration upon the distribution of water through the plant is very great. It sets up a rapid current, known as the "transpiration-current," which travels from the roots upwards towards the leaves. Sachs has made some observations as to its rate by means of the lithium-method, which consists in supplying the root of a plant with a solution of a salt of lithium, and determining by means of the spectroscope the length of stem in which lithium could be detected after the lapse of a given time. He estimates the rate per hour to be in *Nicotiana Tabacum* 118 centimètres (46·458 inches), in *Helianthus annuus* 63 (24·793 inches), and in *Vitis vinifera* 98 (38·583 inches). But the water of the transpiration-current holds salts and other substances in solution. It is clear, therefore, that transpiration promotes the distribution not only of water but also of the substances which the water holds in solution. Sachs's experiments go to prove that salts travel in solution in the current; hence it affords a ready means of transport of substances from the roots, where they are absorbed, to the leaves where (as will be shown below) the food undergoes certain changes which fit it for the nutrition of the plant. There is yet another important point to be noted with regard to the physiological significance of transpiration. It has been mentioned that the roots absorb from the soil only very dilute solutions of salts and other substances, so that for any given quantity of a salt absorbed an excessive quantity of water has to be absorbed likewise. It is obvious that the absorption of salts from the soil by the roots can only go on provided that the plant is able to get rid of the excess of absorbed water, and this is effected chiefly by transpiration, though, as mentioned above, an actual excretion of water in the form of drops not unfrequently takes place.

It has been conclusively proved that the channel along which the transpiration-current travels is the fibro-vascular tissue, and that it is the xylem or woody portion of a fibro-vascular bundle which is the conducting tissue. In the case of plants like Conifers and Dicotyledons, in which there is a formation of secondary xylem or wood from a cambium-layer, it is the younger wood, the alburnum, along which the transpiration-current passes. The older wood, the duramen, it is true, usually contains water, but it does not serve as a conducting channel, only as a reservoir. The question now arises as to the mode in which the transpiration-current travels through the wood. Since the vessels contain no water in their cavities at the time when transpiration is most active, it is clear that it is not in the cavities of the vessels that the water of the current travels. Sachs is of opinion that it moves in the substance of the lignified cell-walls. Others, amongst whom Hartig may be especially named, consider that it travels from the cavity of one wood-cell to that of the next by filtration under pressure. The mechanism of conduction would, in

the latter case, be this: the conducting cells contain air and water; when water is withdrawn from one of them the contained air becomes rarefied, and the water in that cell is then subject to a lower pressure than that in neighbouring cells; as a consequence water is forced into the former cell through the thin membranes of the pits in its walls until equilibrium is re-established. Inasmuch, then, as the air in the conducting wood-cells in the leaves is constantly undergoing rarefaction in consequence of transpiration, a current is set up towards the leaves from the stem and the root.

There can be no doubt, however, that, as Hales first pointed out, transpiration has the effect of diminishing the pressure of the gases contained in the cells and vessels. Von Höhnelt has found that, if the stem of a transpiring plant be cut through under mercury, the mercury will at once rise to a height of several centimètres in the vessels, the greatest height being reached in the younger vessels. This rise can only be accounted for by ascribing it to the difference between the atmospheric pressure and the pressure of the gases in the vessels, the lower pressure of the latter being due to the removal of water by transpiration, which necessarily involves an expansion, and therefore also a diminished pressure of the gases. The effect of this so-called "negative pressure" is to set up diffusion-currents of gases from the surrounding tissues into the cells and vessels of the fibro-vascular bundles. It must not be assumed, however, that the vessels are the principal channels in which gases circulate throughout the plant. They circulate principally in the intercellular spaces which communicate with the external air by means of the stomata.

Stating the foregoing facts in the most general terms, it appears that in a plant the food-materials travel by osmosis from the absorbent organs to the organs in which the processes of constructive metabolism are carried on—in one of the higher plants, for instance, from the roots to the leaves—and that the distribution of the food-materials is assisted and accelerated by root-pressure and by transpiration, the fullest expression of this being the transpiration-current in terrestrial vascular plants. And just as there is a current of food-materials tending towards the organs in which the processes of constructive metabolism are carried on, so also there is a current of the organic nutrient substances formed in these organs travelling from them to the other parts of the plant. The final cause of the current is the same in both cases. A given salt, for instance, which has been absorbed by the root travels towards the leaves because it is in some way undergoing chemical alteration in those organs; similarly, a given organic substance formed in the leaves travels from them towards any part of the plant in which that substance is being chemically altered, or, to use a somewhat different expression, is being consumed. The cause of the diffusion in either case is the disturbance of osmotic equilibrium by the chemical alteration of the substance, and the result is a current of the substance from those parts which are relatively rich in it to those which are relatively poor.

*Distribution of Organic Nutrient Substances.*—In vascular plants the distribution of the organic nutrient substances is, like the conduction of substances absorbed by the roots, assisted by the vascular tissue; but, whereas it is the wood which is the conducting tissue in the latter case, in the former it is the bast or phloem, and more especially the bast-vessels or sieve-tubes. These vessels consist of elongated cells placed end to end, the septa between the adjacent cells being perforated so as to admit of a direct continuity between their protoplasmic contents.

The importance of the wood and of the bast respectively as conducting tissues is well illustrated by the "ringing" experiments which have been repeatedly made on plants,

such as Dicotyledons and Conifers, which have the fibro-vascular bundles arranged in a ring in the stem. When a ring of tissue, extending inwards as far as the cambium-layer, is removed from the stem of a dicotyledonous plant the following facts are to be observed: (1) that the leaves which are borne on branches arising from the stem above the level at which the ring of tissue has been removed will not exhibit any signs of withering; (2) that the part of the stem below the incision will not increase in thickness to nearly the same extent as the part above the incision. From these facts it is clear (1) that the operation in question has not materially affected the conduction of water and food-materials in solution upwards to the leaves, and, since the wood is the only unimpaired tissue, it is obviously in the wood that the upward current travels; and (2) that the operation has materially affected the conduction of organic nutrient substances to the parts below the incision, the diminished growth of these parts being the result of inadequate nutrition; this effect of the operation is to be ascribed, principally at least, to the destruction of the continuity of the bast-tissue.

Laticiferous tissue and vessels.

In various families of vascular plants, and in some cellular plants also (certain Fungi), there are to be found cells, forming what is known as "laticiferous tissue," which probably assist in distributing both food-materials and organic nutrient substances throughout the plant. In some plants (*Euphorbiaceæ*, *Asclepiadaceæ*, *Morææ*, &c.) the cells are quite distinct from each other, and extend from one end of the plant to the other, growing with its growth, so that they attain a very considerable size, and are much branched; these are spoken of as "laticiferous cells." In other plants (*Cichoriaceæ*, *Papaveraceæ*, &c.) the cells are comparatively small, and fuse together to form an intricate network; these are spoken of as "laticiferous vessels." The cells of the laticiferous tissue contain a milky liquid, termed "latex," which consists of water holding inorganic salts, sugar, gum, extractives and proteids, in solution, and holding in suspension resinous and fatty bodies. The cells contain protoplasm in addition, and not uncommonly starch-granules.

#### Food of Plants.

Food of plants.

A rough idea of the nature of its food can be obtained by analysing a plant. It is found that, in the process of incineration, a considerable weight of its dry solid is burned up and given off in the form of gas; this represents the combustible or organic portion of the plant. The incombustible residue, the ash, is found to be of a mineral or inorganic nature. The gases given off are carbon dioxide, watery vapour, and nitrogen, showing that the combustible portion of the plant contained the elements carbon, hydrogen, and nitrogen. In the ash occurs a number of elements, of which the principal are sulphur, phosphorus, potassium, calcium, magnesium, iron, sodium, chlorine, and silicon. But it does not necessarily follow that, because any given chemical element can be detected in a plant, that element is to be regarded as part of the food of the plant, for, as has been already pointed out, plants may absorb substances which in no way contribute to their nutrition, or are even injurious. When an element enters into the chemical composition of the substances of which the organized structure of the plant consists (as C, H, O in starch and cellulose, C, H, O, N, S, P in proteids), then it is clear that this element must form part of the food; but, when, as in the case of the rest of the elements mentioned above, an element does not thus contribute to the building up of the organized substance of the plant, its admission to the rank of a food-material must be the subject of direct experiment. It has been ascertained that many of the elements enumerated above,

though, so far as is known, they are not essential constituents of the organized structure of the plant, are nevertheless essential to the maintenance of its life; they may not, indeed, go to build up the plant-substance, but in some way or other they promote the metabolic processes.

The method which has afforded the most valuable results Water-bearing upon the relative physiological importance of culture. various food-materials is that which is known as "water-culture." It consists in growing plants with their roots immersed in water holding certain salts in known quantities in solution. The mixture of salts can, of course, be varied at pleasure, and the effect upon the plant of the absence of certain elements, as of their presence in smaller or larger quantities, can be observed. Further, by an analysis of that portion of the solution which remains unabsorbed at the close of the experiment, the proportion in which the various salts have been absorbed can be ascertained.

The elements of the food of plants may be conveniently classified into two groups, the first consisting of those which enter into the composition of organized plant-substance, the second consisting of those which, without actually entering into the structure of the plant, are essential to the proper performance of the metabolic processes. To the first group belong the elements C, H, O, N, S, P; to the second, K, Ca, Mg, Fe, Cl (?).

We will now briefly discuss the form in which the various chemical elements are absorbed, and their use in the economy of the plant, beginning with those which enter into the composition of organized plant-substance. A few words will also be said about those elements, such as sodium and silicon, which, though always present in the ash of plants, appear to have no real physiological significance as far as nutrition is concerned.

**Carbon.**—This element constitutes a large percentage of the total Food dry weight of plants. It enters into the composition of all the elements, organic substances, such as starch, cellulose, and other carbohydrates, fats and other hydrocarbons, proteids, organic acids, alkaloids, &c., which may be present in plants. The form in which carbon is absorbed depends upon the nature of the plant. It may be broadly stated that all those which contain chlorophyll absorb their carbon in the form of carbon dioxide, whereas those which do not contain chlorophyll absorb their carbon in the form of more complex carbon compounds which contain C, H, and O, and in which the C is directly combined with H. Moreover, in green plants it is only those cells which contain chlorophyll that can absorb carbon dioxide, and this only under the influence of light. It must not be assumed, however, that plants containing chlorophyll are incapable of absorbing complex carbon compounds. It is known from the researches of Darwin and others that the "insectivorous" plants absorb such compounds by their modified leaves, and it is known also that a number of green plants, such as the Mistletoe, the Rattle, and others, live parasitically on other plants. It has indeed been proved by direct experiment that green plants can absorb substances such as urea, glycocoll, asparagin, leucin, tyrosin, which are all highly complex carbon compounds. The physiological distinction to be drawn between plants which do and those which do not contain chlorophyll is really that the former are capable of assimilating carbon in a simple compound, such as CO<sub>2</sub>, whilst the latter are incapable of doing this, and require, therefore, compounds of more complex constitution. Plants which do not contain chlorophyll are either parasites (that is, they live upon other living organisms) or saprophytes (that is, they live upon the products of the waste and decay of other living organisms). The Phanerogams.—*Epipogon Gmelini*, *Cuscuta*, *Monotropa*, *Lathræa*, *Corallorhiza*. Of these the Fungi include both parasites and saprophytes; *Epipogon Gmelini* is a saprophyte, *Cuscuta* a parasite, *Orobanchæ*, which are parasitic, and *Acetia*, which is saprophytic, have not a green colour, but small quantities of chlorophyll have nevertheless been detected in them.

**Hydrogen.**—This element is absorbed by all plants in the form of water and of ammonia and its compounds; it may also be absorbed in the form of organic compounds.

**Oxygen.**—Oxygen is taken up either in the free state, or in combination in the form of water or of salts; it may also be absorbed in the form of organic compounds. The free oxygen absorbed is especially concerned in the processes of destructive metabolism, the combined oxygen in those of constructive metabolism.

**Nitrogen.**—Nitrogen is absorbed in the form of ammonia and its compounds and of nitrates; it may also be absorbed in the form of organic nitrogenous compounds. The researches of Lawes, Gilbert, and Pugh, as also those of Boussingault, have proved that plants are incapable of assimilating free nitrogen. It appears that, on the whole, nitrogen absorbed in the form of ammonia compounds is more readily assimilated by plants than nitrogen absorbed in the form of nitrates. Pasteur has shown, for instance, that the Yeast plant cannot assimilate nitrates.

**Sulphur.**—Sulphur is absorbed from the soil as sulphates, those of ammonium, potassium, magnesium, and calcium being the most advantageous. It may also be absorbed to some extent in the form of organic compounds.

**Phosphorus.**—Phosphorus is absorbed from the soil in the form of phosphates. Besides being a constituent of certain substances allied to the proteids, such as nuclein and plastin, phosphorus seems to bear an important relation to certain of the metabolic processes. Phosphates are to be found especially in those parts of plants which are rich in protoplasmic cell-contents. It appears that a supply of phosphates promotes considerably the assimilation of nitrogen by the plant.

**Potassium.**—Potassium is absorbed in the form of a variety of salts, of which the chloride is the most advantageous form, according to Nobbe. Like phosphorus, it is to be found in largest quantity in those parts of plants which are rich in protoplasmic cell-contents. It appears to have an important influence on the constructive metabolic processes of plants which contain chlorophyll. Nobbe found, in the case of a Buckwheat plant, that in the absence of a supply of potassium its growth was diminutive, and that the amount of starch in the plant was very small. On the addition of potassium chloride to the water-culture the starch-grains became more numerous in the chlorophyll-corpuscles, and made their appearance also in the tissues of the stem. The precise significance of potassium in relation to these processes is not known. Liebig was of opinion that it played an important part in the distribution of carbohydrates throughout the plant, but this view has not been confirmed. It appears rather that the facts upon which this view was based point to an effect due not to the potassium itself but to the particular salt of it which was absorbed (see "chlorine" below). There can be no doubt, however, that potassium bears some important relation to the formation and storing up of carbohydrates, for it is always present in large quantity in organs, such as leaves, tubers, seeds, &c., in which these processes especially take place.

**Calcium.**—The compounds in which calcium is usually absorbed are the sulphate, phosphate, nitrate, and carbonate, the last-named salt undergoing decomposition in the process. It appears that the chloride is injurious to plants. The precise use of calcium is unknown. It very commonly occurs in the cells of plants in the form of crystals of the carbonate or the oxalate, and possibly one of its important functions is to form insoluble salts with acids which are of no further use in the plant, and are even injurious to it.

**Magnesium.**—Like calcium, this may be advantageously absorbed in the form of all its salts, except the chloride. Nothing definite is known as to its use.

**Iron.**—It appears that iron may be absorbed in the form of any of its salts. It is known to be essential only to those plants which contain chlorophyll. If a seedling be cultivated by the method of water-culture, with its roots in a solution which contains no iron, the leaves formed will be successively paler in colour until at length they are nearly white; in this state the plant is said to be "chlorotic." If a small quantity of a salt of iron be then added to the solution in which the roots are, or if the pale leaves be painted over with a dilute solution of iron, they will soon become green. Iron, therefore, plays an important part in connexion with the formation of the green colouring-matter chlorophyll. It is still a debated question whether or not iron enters into the composition of the chlorophyll-molecule.

**Chlorine.**—Chlorine is absorbed from the soil in the form of chlorides. The evidence as to its significance in the nutrition of plants is conflicting. Nobbe, Leydhecker, Beyer, and more recently Farsky have observed that water-cultures of Buckwheat, Barley, and Oats do not flourish when grown in solutions containing no chlorides, and since the chlorophyll-corpuscles of the plants become crowded with starch-grains it was thought that chlorine had some importance in connexion with the translocation of carbohydrates. Knop and Dworzak have observed, on the other hand, that Maize plants will grow well in solutions containing no chlorine, and further, that the accumulation of starch in the chlorophyll-corpuscles may be induced by various abnormal external conditions.

**Sodium.**—This element is never absent from the ash of plants, and in some cases, especially in maritime plants, it is present in considerable quantity. It might be inferred from its constant occurrence in the ash that sodium is of some importance as a food-material; it was thought, in fact, that it might serve as a substitute for potassium, but this has not been found to be the case. Its constant presence in the ash is due merely to its universal distribution in the soil.

**Silicon.**—Silicon is absorbed in the form of soluble silicates, and possibly as soluble silicic acid. The silicates are brought into solution to some extent by the carbon dioxide present in the soil, and also by the acid sap of the root-hairs. It is always present in the ash of plants, sometimes in large quantity; in wheat-straw, for instance, it constitutes 67.50 per cent. of the ash (Wolff). It was thought that silicon must be essential to nutrition. Sachs found, however, that a Maize plant will grow well in a water-culture from which it can obtain no silicon. On the other hand, Wolff has ascertained that in the case of Oats the number of perfect seeds formed is greater when the plant is abundantly supplied with silicon.

### Constructive Metabolism (Anabolism).

When a plant is adequately supplied with appropriate Meta-food-materials, the external conditions to which it is exposed being favourable, it increases in weight, owing to an accumulation of the substances which constitute its organized structure. But this gain in weight is only relative; for side by side with the constructive processes by which the food is converted into the substance of the plant—processes, that is, which have as their result the formation of relatively complex from relatively simple chemical compounds—there are going on destructive processes—processes, that is, which have as their result the formation of relatively simple from relatively complex chemical compounds—which are attended by a loss of weight. The gain in weight by the plant represents the difference between the activity of the constructive and of the destructive metabolic processes respectively. The end of constructive metabolism is the formation of protoplasm. Protoplasm is certainly a very complex substance, though its precise constitution is unknown, and the food-materials of plants are much simpler substances; there must, therefore, be a considerable number of processes to be gone through before protoplasm can be produced from the food-materials. We will now study these processes, and, in the first instance, confine our attention to those which have been ascertained to take place in plants which possess chlorophyll.

It has been already mentioned that a green plant absorbs carbon dioxide when it is exposed to light. Under these circumstances it also increases in weight; it does not increase in weight when kept in the dark, nor when it is kept in an atmosphere from which all carbon dioxide has been removed. The absorption of carbon dioxide is then an indication that the plant is performing certain constructive processes,—that it is assimilating carbon. The absorption of carbon dioxide is accompanied by an evolution of oxygen gas, the volume of the latter exhaled being approximately equivalent to that of the carbon dioxide absorbed. This is an indication that the absorbed carbon dioxide is undergoing chemical change. It seems probable that the change is of the nature expressed by the following equation—

—that is, that from carbon dioxide and water a substance allied to formic aldehyde, or a polymer of it, is formed, free oxygen being evolved. It may be stated generally, with some considerable probability, that the first step in the constructive metabolism of a plant containing chlorophyll is the formation of a non-nitrogenous organic compound. It is just this formation of non-nitrogenous organic substance from carbon dioxide and water that the plant which is destitute of chlorophyll is unable to perform; and it is on account of this inability that the carbon of its food must be supplied to it in the form of organic compounds, as pointed out above. The further processes of constructive metabolism appear to be much the same in all plants, whether they contain chlorophyll or not. The next step is probably the formation of some relatively simple nitrogenous organic substances from the nitrogen of the food and the non-nitrogenous organic substance

which has been either formed in the plant or absorbed as food from without. The nitrogenous substances thus formed are probably crystallizable bodies, such as asparagin and leucin, which all contain nitrogen in the form of the group  $\text{NH}_2$ . The derivation of these substances from the nitrogenous food when it contains nitrogen in the form of ammonia ( $\text{NH}_3$ ) is sufficiently obvious. When, however, it consists of nitrates it appears probable that the nitrogen of the nitric acid has to be transformed into the nitrogen of ammonia,—that is, to be combined directly with hydrogen; it is probably owing to their inability to effect this transformation that some plants, as mentioned above, cannot be supplied with nitrogen in the form of nitrates. The first step in this transformation is probably, as Emmerling has pointed out, the decomposition of the absorbed nitrates by the organic acids, especially the oxalic, of the plant; the liberated nitric acid then undergoes chemical change, resulting in the formation of ammonia. It is impossible to say with precision how this is effected, but there can be little doubt that it does take place; some direct evidence is afforded by Hosaens's observation that ammonia salts were to be found on analysis in a number of plants which had been supplied with manure containing no ammonia. The next process is an increase in the size and complexity of the molecule, attended in certain cases by the introduction of new elements (S and P), the product being one of those substances which are known as "proteids." The last stage is the formation of living protoplasm from the proteid and other organic substances.

Formation of nitrogenous organic substance.

The formation of nitrogenous organic substance may take place in any living cell, and, unlike the formation of non-nitrogenous organic substance, it goes on quite independently of the presence of chlorophyll and of the action of light. But there is evidence to show that in green plants it is especially in the cells which contain the chlorophyll that the process goes on. The experiments by which this evidence has been obtained were made on plants with distinctly differentiated leaves. Emmerling observed in the Bean that, whereas in the root a relatively large quantity of nitric acid could be detected, there was much less in the stem, and in the leaves none at all, and he inferred that as the nitrates are supplied to the leaves they are used up in the formation of organic nitrogenous substance. Further, from the researches of Kellner, Emmerling, Borodin, and others it appears that the leaves contain the above-mentioned crystallizable organic substances, asparagin, leucin, &c., in considerable quantity; and it is quite possible that these substances may be formed synthetically in the leaves, though it is true that they may be formed in other ways as well. Finally, Pott has found that the proportion of proteid in the plant increases from the roots upwards towards the leaves, the proportion in the latter being about twice as great as that in the former of many of the plants which he analysed.

The formation of living protoplasm from the organic substances elaborated from the food necessarily goes on in every living cell. It has been already mentioned that destructive metabolism—that is, processes of decomposition—is active in living cells, and it is especially the protoplasm which is the seat of these processes. The maintenance of the life of the cell is therefore an indication of the fact that the activity of the destructive metabolism is at least equalled by the activity of the constructive metabolism. In a young cell the latter exceeds the former, so that the protoplasm is increased in quantity; then for a time the two are approximately equivalent, until at length the destructive gradually gains the upper hand, and eventually the death of the cell is the result.

### Destructive Metabolism (Katabolism).

Just as all the processes by which increasingly complex organic substances are formed in the plant, and which intervene between the food-materials on the one hand and the protoplasm on the other, are designated collectively "constructive metabolism," so all the processes of decomposition by which relatively simple substances are produced from relative complex ones, and which intervene between the protoplasm on the one hand and the excreta and other waste-products on the other, are designated collectively "destructive metabolism." Of all the various processes of destructive metabolism the most fundamental is the decomposition of the protoplasm. It appears that this decomposition is spontaneous—that it is, as Pflüger terms it, a "self-decomposition"; and it is, in fact, only so long as this self-decomposition is proceeding that protoplasm can be said to be living. The destructive metabolism of an organism is not, however, confined to the self-decomposition of its protoplasm; the various complex organic substances which the cells contain may undergo chemical change quite independently of their entering into the metabolism of the protoplasm. The most active agents in producing chemical changes of this kind are certain bodies which are termed "ferments," and are distinguished as "unorganized" ferments from the so-called "organized" ferments, such as Yeast and Bacteria. But little is known as to their chemical composition, and nothing as to the peculiarity of chemical constitution upon which their characteristic properties depend.

The unorganized ferments which have hitherto been detected in plants may be classified, according to the nature of the chemical changes which they induce, in the following four groups.

1. Ferments which convert starch into sugar (diastatic ferments). These have been found to be very widely distributed in plants, and in fact it seems probable that a ferment of this kind is present in all living plant-cells. Their mode of action is generally indicated by the following equation—

2. Ferments which convert cane-sugar into glucose (inverting ferments). A ferment of this kind, termed "invertin," has been obtained from Yeast; it is probable that a similar ferment is present in succulent fruits, for they commonly contain a mixture of cane-sugar and glucose. The following equation will indicate the nature of the process—

3. Ferments which decompose glucosides. The most familiar members of this group are emulsin or *synaptase*, found in the Bitter Almond; myrosin, in the seed of the Black Mustard; erythrozym, in the root of the Madder. The following equation represents the decomposition of the glucoside amygdalin by emulsin—

4. Ferments which convert proteids that are indiffusible and may be insoluble in water into others (peptones) which are both soluble and diffusible. These, which are only active in the presence of free acid, are termed "peptic" ferments. They have been found in quantity in the latex of certain plants (*Carica Papaya* and *Ficus Carica*) and in the liquid excretion of carnivorous plants. It is, of course, impossible to represent by an equation the nature of the chemical change which these ferments induce.

It is probable that other ferments than these may be present in plants, but they have not yet been actually obtained. There is probably one which decomposes fats (glycerides) into glycerin and the corresponding fatty acid, thus—

Müntz and Von Reichenberg have pointed out that the quantity of free fatty acids in oily seeds increases very much during germination, and the only satisfactory explanation of this fact which can at present be offered is that it is the result of the decomposition of the fats, in the manner indicated above, by an unorganized ferment. Again, it was mentioned above that crystallizable nitrogenous organic substances, such as leucin, asparagin, and tyrosin, occur in plants, and it was pointed out that they may be formed synthetically. But there can be no doubt that they may be, and frequently are, formed analytically,—that is, by the decomposition of more

complex substances. For instance, when the seeds of leguminous plants, such as the Pea or the Bean, germinate, the quantity of proteid substance diminishes, and the quantity of amides, notably asparagin, increases; there can be no doubt that the latter are derived from the former. It is well known that similar changes take place in the pancreatic digestion of animals, that leucin and tyrosin are formed from proteids, and that this is effected by an unorganized ferment termed "trypsin"; it is quite possible that a ferment of this kind may be present in plants. Finally, there is probably, in certain plants at least, a ferment which converts cellulose into sugar. For instance, the Date seed contains a quantity of non-nitrogenous reserve material stored up as cellulose in its very thick cell-walls; on germination this undergoes absorption and is conveyed to the embryo; it is extremely probable that the conversion of the insoluble cellulose into some soluble substance (doubtless sugar) is effected by the action of a ferment. The penetration of the absorbent organs of parasites into the tissues of their hosts is probably effected by the action of a ferment of this kind which is excreted by the parasite.

But there are still other chemical changes to be accounted for as the result of which substances relatively rich in oxygen are produced from others which are relatively poor in that element. Some of these are, so far as is known, processes of simple oxidation, which go on as readily outside the organism as within it; for instance, chlorophyll is oxidized quite as readily in alcoholic solution as when it exists in the chlorophyll-corpuscles of a plant; these processes of simple oxidation may then be regarded as going on independently of the vital activity of the organism. But there are other and more complex oxidations which may be termed "oxidative decompositions"; these involve something more than mere oxidation, and appear to depend upon the vital activity of the organism.

The following instances may be given to illustrate the nature of these changes. Ethyl-alcohol becomes oxidized, under the influence of a Fungus known as the *Mycoderma Aceti*, as follows—

Another similar Fungus, the *Mycoderma Fini*, induces a more complete oxidative decomposition of alcohol,—carbon dioxide and water being the products of its action. Again, a substance termed "pyrocatechin" and various organic acids occur in plants, and there seems reason, from the researches of Hoppe-Seyler and of Carl Kraus, to believe that they are derived from carbohydrates in some such way as the following—

it being understood that this suggests only one of the ways in which the vegetable acids are formed.

There are yet other processes of decomposition which, like the oxidative decompositions, are effected under the influence of living protoplasm, but which, unlike them, do not depend upon the presence of oxygen; on the contrary, these decompositions, which may be generally termed "fermentations," depend upon the absence of free oxygen, for their activity is the greater the more limited the supply of this element. A characteristic example of this kind is afforded by the decomposition of sugar into alcohol and carbon dioxide, which is effected by Yeast, and is known as the "alcoholic fermentation." Its nature is indicated by the following equation—

Again, various forms of Bacteria effect decompositions of this kind. Of these the putrefaction of organic matter, the lactic and butyric fermentations, are examples. It must not be supposed, however, that the property of exciting fermentation is confined to the protoplasm of lowly plants such as Yeast and Bacteria. It has been found that various fermentations are set up when living plant-organs of any kind—leaves, flowers, fruits, seeds—are kept in an atmosphere which contains no free oxygen.

The characteristic accompaniment of the destructive metabolism of plants, as of all living organisms, is, under normal conditions, that interchange of gases between the plant and the atmosphere which is known as "respiration," and which consists in the absorption of oxygen and the

evolution of carbon dioxide. It may be stated generally that the continual absorption of free oxygen is essential to the existence of at least the more highly-organized plants, and that in the absence of a supply of free oxygen they die. Death under these circumstances is to be attributed to the arrest of those metabolic processes which are accompanied by an evolution of kinetic energy in the organism—that is, of the destructively metabolic processes; and of these by far the most important is the self-decomposition of the protoplasm. It would appear that the absorption of oxygen is essential to the self-decomposition of the protoplasm-molecule. It is impossible to say anything definite as to the mode in which oxygen affects this process. Pflüger has, however, suggested that the absorbed oxygen enters into the protoplasm-molecule as "intramolecular" oxygen, that the molecule is thereby rendered unstable, and that it then readily undergoes decomposition.

In contrast to the plants which continue to live only when supplied with free oxygen (the *aerobia*, as Pasteur has termed them) stand the *anaerobia*—those, namely, which thrive best in the absence of free oxygen, and to which, in certain cases, the access of free oxygen is fatal; of the latter, certain *Schizomycetes* and *Saccharomycetes* may be taken as examples. It is remarkable that it is just the anaerobiotic plants which are most highly endowed with the property of exciting fermentation; and this, taken in conjunction with the fact that the activity of fermentation stands in an inverse relation to the supply of free oxygen, indicates the existence of some sort of correlation between the normal respiratory and the fermentative processes. It appears that in aerobiotic plants the normal processes of destructive metabolism, of which the absorption of oxygen and the evolution of carbon dioxide are the outward expression, may be replaced for a longer or shorter time by those abnormal processes of which fermentation is the outward expression; in completely anaerobiotic plants the fermentative are the normal processes. It is difficult to explain the physiological significance of fermentation, and to determine the manner in which it contributes to the maintenance of the life of the organism. Pasteur has suggested that it is the expression of an effort of the organism to obtain oxygen from substances which contain it in combination. Another possible view is that the organism obtains, by the fermentative decomposition of the substances upon which it acts, the supply of energy which, in the case of an aerobiotic plant, is afforded by the normal decomposition of its own protoplasm-molecules.

The products of destructive metabolism are extremely numerous and of very different chemical nature. They may be roughly classified into two groups: (1) the *waste-products*, substances which cannot be used in the constructive metabolism of the plant, and which may be excreted; and (2) the *plastic products*, substances which can enter into the constructive metabolism.

1. *Waste-Products*.—Among the waste-products the most constant are carbon dioxide and water, which are exhaled in respiration; it may, in fact, be stated generally that all living plants and parts of plants exhale carbon dioxide and watery vapour at all times. There is, however, no constant relation between the volumes of carbon dioxide exhaled and of oxygen absorbed in respiration, and the processes of destructive metabolism, of which the respiratory interchange of gases is the external expression, are so complex that the relation, whatever it may be, between the volumes of these gases in any particular case cannot be accounted for. The degree of independence between these processes is well illustrated by the fact that the absorption of oxygen is relatively greater at low temperatures, and that the exhalation of carbon dioxide is relatively greater at high temperatures. This seems to indicate that at a

low temperature the storing-up of intramolecular oxygen is relatively more active than the decomposition of the protoplasm-molecules, whereas at a high temperature the converse is the case. At medium temperatures these processes are about equally active, for it has been ascertained in various cases that the volumes of oxygen absorbed and of carbon dioxide exhaled are under these circumstances approximately equal. It must not, however, be concluded that the exhalation of carbon dioxide is entirely independent of the absorption of oxygen, for the observations of Broughton, Wilson, and Wortmann all show that when plants are deprived of a supply of free oxygen the activity of the exhalation of carbon dioxide rapidly diminishes.

Among the other waste-products the following are those which are of most common occurrence,—organic acids, aromatic substances, colouring matters, bitter principles, certain fatty bodies, alkaloids.

organic  
acids.

(1.) *Organic Acids*.—The organic acids are very generally present in plants, either free or in combination with organic or inorganic bases, and it is to the presence of these acids or of their acid-salts that the acid reaction of plant-tissues is due. Those most commonly occurring are the malic, tartaric, citric, oxalic, and fatty acids, the last-named being generally in combination with glycerin, forming fats (glycerides). There can be little doubt that they are to be regarded as products of destructive metabolic processes, though Liebig regarded some of the more highly-oxidized acids as the first products of constructive metabolism, and as being formed from carbon dioxide and water in the cells which contain chlorophyll. It is not so clear that they are all to be regarded as waste-products; it appears possible that some of the less highly-oxidized may undergo reduction with the formation in carbohydrates, for it has been observed, especially by Beyer, that in ripening fruits the acids diminish and the sugar increases in quantity. Again, there can be no doubt that fats enter into constructive metabolism, and hence the fatty acids must be regarded as plastic products. The more highly-oxidized acids are almost certainly waste-products. Oxalic acid, for instance, is commonly found as crystals of calcium oxalate which, in most cases at any rate, undergo no alteration. It appears that the oxalic acid is withdrawn in this way from the sphere of metabolism, and, inasmuch as these crystals are deposited especially in the deciduous parts of the plant, it is also ultimately got rid of. It is probable that the organic acids are largely produced as the result of oxidative decompositions (see *supra*). There can be no doubt that the self-decomposition of protoplasm is attended by a formation of acids, especially of nitrogenous acids, such as the aspartic and glutamic, and of fatty acids.

In addition to their significance in the constructive metabolism of plants the organic acids are of use in other ways. Their presence in the living cells contributes to the maintenance of the turgid condition; the presence of acid-sap in the root-hairs renders possible the solution and absorption of mineral substances which are insoluble in water; oxalic acid, at least, decomposes the salts absorbed by the roots; and finally it appears that the organic acids are capable of inducing the conversion of one carbohydrate into another—cane-sugar into glucose, for instance—and they may in this way play an important, though hitherto undetermined, part in the general metabolism of plants.

aroma-  
tic sub-  
stances.

(2.) *Aromatic Substances*.—These occur generally in the form of glucosides, the most common of which is tannin. The glucosides are bodies, for the most part non-nitrogenous, which yield sugar on decomposition amongst other substances. In so far as they yield sugar they may be regarded as plastic products; but the aromatic substances to which they give rise on decomposition are waste-products, for it appears from the observations which have been made on this point that the higher plants, at least, cannot avail themselves of carbon when combined in an aromatic molecule for the purposes of their constructive metabolism. Probably the resins which are so commonly present in plants are derived from tannin. The first step is the formation of a terpene ( $C_{10}H_{16}$ ) in the secreting cells; this is then excreted into the ducts and undergoes partial oxidation with the formation of resin. In connexion with the terpenes two hydrocarbons, caoutchouc and gutta-percha ( $C_{20}H_{32}$ ), may be mentioned, which occur in the latex of certain plants.

It is not possible to make any definitive statement as to the mode of origin of the aromatic substances in the plant, but the fact that tannin is constantly present in the cells of parts in which destructive metabolism is active—growing points, mobile organs of leaves, galls, for example—tends to prove that this glucoside at least may be derived from protoplasm. It must not be overlooked, too, that substances like tyrosin, which contain an aromatic radical, occur in plants, and that they are derived more or less directly from

(3.) *Colouring Matters*.—The principal colouring matters of Colour-plants are—(a) those which occur in the walls of the bark-cells of trees and shrubs (phlobaphenes); (b) those of woods, such as matters in logwood; (c) those which occur in solution in the cell-sap, as in most flowers; (d) those which occur in connexion with protoplasmic corpuscles, as in the *Algae* and in the leaves and other green parts of the higher plants. With regard to the three first-named groups it appears probable that they are derived in various ways from tannin.

Of the colouring matters which occur in connexion with protoplasmic corpuscles by far the most important is chlorophyll, the substance to which plants owe their green colour. The corpuscle has a spongy structure, the interstices of which are occupied by the chlorophyll in solution in some fatty substance. The other colouring matters which may be present in corpuscles are—*etioline*, yellow, which is apparently present in all chlorophyll-corpuscles, conspicuously so in those in parts of normally green plants which have been growing in darkness, and is apparently an antecedent of chlorophyll; *xanthophyll*, also yellow, and commonly present in chlorophyll-corpuscles, especially in those of fading leaves, probably a derivative of chlorophyll; *anthoxanthin*, also yellow, the colouring matter of yellow flowers, and a derivative of chlorophyll; *phycozanthin*, brownish, present in the chlorophyll-corpuscles of the brown *Algae* (*Phaeophyceae* or *Melanophyceae*); *phycoerythrin*, red, present in the chlorophyll-corpuscles of the red *Algae* (*Rhodophyceae*, *Florideae*).

Chlorophyll is a substance of such great physiological importance that the conditions of its formation and its properties must be treated of in some detail. The general conditions upon which its formation depends are (a) exposure to light, (b) a sufficiently high temperature, (c) a supply of iron. Plants which are normally green are not green if they have been grown in the dark, or if the temperature has been too low, or if they have not been supplied with iron; they are usually yellow, and in the last case especially they may be quite colourless. Normally green plants which have been kept in the dark or at too low a temperature are said to be "etiolated," since they form etioline; plants which have grown in absence of a supply of iron are said to be "chlorotic." There are good grounds for regarding etioline as an antecedent to chlorophyll. It is formed in the corpuscle in darkness and at a temperature lower than that which is necessary for the formation of chlorophyll. It appears from the researches of Gris, Mikosch, and others that when the corpuscle is about to form etioline it contains a starch-granule, and that as it assumes a yellow colour the included starch-granule diminishes in size and may disappear. It must not be inferred from this observation that the etioline is directly formed from the starch. It is more probable that it is derived from the protoplasm, and that, as the protoplasm is consumed in the formation of the etioline, the starch is used in the construction of fresh protoplasm. Under the influence of light and of a sufficiently high temperature the yellow etioline is converted into the green chlorophyll, but nothing is known as to the nature of the process by which the conversion is effected.

With regard to the physical properties of chlorophyll it has long been known that it is soluble in alcohol, ether, benzol, chloroform, carbon disulphide, and various oils. Hansen has obtained, by a process of saponification, from the alcoholic extract of leaves a green crystalline substance, probably the purest form of chlorophyll yet obtained, which is readily soluble in water. All solutions of chlorophyll in the above-mentioned media are fluorescent,—that is, when they are viewed by reflected light they appear opaque and of a deep lake-red colour, but when thin layers are viewed by transmitted light they appear green. If the light which has passed through a layer of a moderately strong solution be examined with the spectroscope a characteristic absorption-spectrum will be observed. Beginning at the red end of the spectrum, a well-marked dark band will be seen between Fraunhofer's lines B and C, extending rather beyond C, a second dark band in the orange between C and D, a third very faint band at the

junction of the yellow and the green, and a fourth more distinct band in the green near F. When an alcoholic extract of leaves is used, as is ordinarily the case, the whole of the blue end of the spectrum beyond F is absorbed, in consequence of the coalescence of three broad bands, which can be seen separately when a very dilute solution is used, two of the bands being in the blue between F and G, and one at the end of the violet. The spectrum of the alcoholic extract presents then seven bands in all. According to Hansen, the spectrum of solutions of his crystallized chlorophyll possesses only the first four of the above-mentioned bands, and it is only when very thick layers are used that the blue end of the spectrum is absorbed; this is true also of the spectrum of the green colouring matter obtained by Tschirch.

Little is as yet known as to the chemical composition of chlorophyll. Gautier and Hoppe-Seyler have both obtained a crystalline green substance from the alcoholic extracts of leaves, termed by the latter "chlorophyllan," which is not to be regarded as pure chlorophyll. The following are their analyses of this substance, to which is added for comparison Hansen's analysis of the green crystalline substance which he obtained—

	Gautier.	Hoppe-Seyler.	Hansen.
C.....	73.97	73.31	60.33
H.....	9.80	9.72	9.37
N.....	4.15	5.68	4.77
O.....	10.33	9.54	14.77
Ash .....	1.75	{ P. 1.38 } { Mg. 0.34 }	10.76

Hansen states that the ash found by him is due to the previous processes of preparation, and that the only normal ash-constituent is iron, which neither Gautier nor Hoppe-Seyler had discovered. Tschirch on reducing chlorophyllan by means of zinc-dust has obtained a green substance which does not crystallize, and is soluble in alcohol, ether, and oils, but not in water. This he believes to be pure chlorophyll. From the percentage composition of the crystals of chlorophyllan Gautier deduces the formula  $C_{19}H_{22}N_2O_3$ , and draws attention to the similarity between this and the formula of bilirubin ( $C_{16}H_{11}N_2O_3$ ). Hoppe-Seyler concludes that chlorophyllan contains phosphorus in its molecule, and is either a lecithin or a lecithin compound. Sehunck has found that the residue of an ethereal solution of chlorophyll when treated with sulphuric or hydrochloric acid yields glucose amongst other products; he therefore regards chlorophyll as a glucoside.

Bitter  
prin-  
ciples.

(4.) *Bitter Principles*.—It has been ascertained that some of these are glucosides, and some alkaloids, but the chemical nature of many of them is still undetermined. Such are santonin ( $C_{12}H_{14}O_3$ ), aloin ( $C_{12}H_{16}O_2$ ), quassin ( $C_{10}H_{12}O_3$ ). It is impossible at present to say anything as to the possible mode of their origin or as to their physiological significance in the plant.

Fatty  
bodies.

(5.) *Certain Fatty Bodies*.—The ordinary fats (glycerides) are to be regarded as plastic products, and they will be subsequently treated of under that head. But there are certain fatty bodies of which this statement cannot be made; these are cholesterol, lecithin, and wax. It is not known how these substances are formed, but probably they, like the ordinary fats, are derived from protoplasm. This view is especially probable with regard to lecithin, which is a nitrogenous and phosphorized fat. Wax occurs especially in the external cell-walls or on the surface of those parts of plants which have a cuticularized epidermis; the "bloom" on fruits, for example, is a layer of wax.

Alka-  
loids.

(6.) *Alkaloids*.—The alkaloids are regarded as waste-products, because, as the observations of Knop and Wolff show, the demand for combined nitrogen cannot be met by supplying the plant with it in the form of alkaloids, though the plant can avail itself of such organic nitrogenous substances as urea, uric acid, leucin, tyrosin, or glycocoll. The alkaloids are compound ammonias which are not volatile at ordinary temperatures. With regard to their mode of origin in the plant, there can be little doubt that they are derived more or less directly from protoplasm, or at least from proteid, as are urea and uric acid in the animal body. But, although these nitrogenous waste-products are formed in the destructive metabolism of plants, their formation is not accom-

panied by a loss of nitrogen, for they are not excreted, as is the case in animals, but are deposited in the cells.

2. *Excretion*.—Of the waste-products, some, such as oxygen, water, and carbon dioxide, are excreted in the gaseous form—the oxygen and the carbon dioxide through the superficial cell-walls of the plant, the watery vapour through the stomata. Some of the carbon dioxide may combine with earthy bases to form carbonates, which are either retained in the plant or excreted in solution. The resins and ethereal oils, as well as wax, are frequently excreted. The mechanism of excretion is widely different in different cases. The resins and ethereal oils are usually excreted by means of special glandular organs. The gland may be a hair on the surface, and it is then commonly the terminal cell at the free end which is secretory; or it may be a group of epidermal cells between which large intercellular spaces are formed, which serve as receptacles for the excreted substance; or it may be formed by the absorption of the adjoining walls of a group of cells belonging partly to the epidermis and partly to the underlying ground-tissue, a cavity being thus constructed, which contains the excreted substance; or again, longitudinal strands of cells may become separated so as to enclose an elongated intercellular space into which they excrete (resin-ducts). In many cases the substance to be excreted may be detected in the glandular cells; not unfrequently, however, and always in the case of wax, no trace of it can be discovered in the cells themselves; it is first to be found in the cell-walls between the cuticular and the deeper layers. The actual excretion is usually effected, in the case of superficial glands, by the rupture of the cuticle which is continuous over the gland, and by the consequent escape of the contents; in some cases the gland remains closed, and any volatile substances (etheral oil) which may be present escape by evaporation.

The excretion of the earthy carbonates in solution is most commonly effected by means of a well-developed gland. Such a gland consists of a group of modified parenchymatous cells in connexion with the termination of a fibro-vascular bundle; and one or two openings, termed "water-pores," and somewhat resembling stomata, are present in the epidermis immediately over it. Under the action of the root-pressure the gland excretes water which holds the carbonates in solution. Glands of this kind are present in the leaves of various Saxifragaceae and Crassulaceae plants. In other cases these salts appear to be excreted by ordinary epidermal cells. In certain Ferns (various species of *Polypodium* and *Aspidium*), for instance, scales of calcium carbonate are found on depressions in the surface of the leaves which are situated immediately over the terminations of the fibro-vascular bundles.

It not unfrequently happens that plants excrete substances other than waste-products, but this has the effect of securing indirect advantages. In the great majority of flowers there are glandular organs which excrete a watery fluid holding principally sugar in solution; these organs are termed "nectaries," and the excretion "nectar." The nectary has essentially the same structure as the water-gland described above, the only important difference being that, whereas the gland is sunk in the tissue and is covered by the epidermis, the nectary has a large free surface, so that the nectar is at once poured out on to the exterior. But there is an important functional difference between them, namely, that, whereas excretion by the gland can only take place under the influence of the root-pressure, excretion by the nectary is independent of the root-pressure, for it will continue when the flower has been removed from the plant. Another instance of an excretion of this kind is afforded by the carnivorous plants. The glands of their leaves excrete a watery liquid which holds in solution a peptic

Nectary  
excre-  
tion.

In philosophy the Poles (as the Slavs generally) have produced but few remarkable names. Goluchowski, the brothers Andrew and John Suiadecki, the latter of whom has gained a reputation almost European, Bronisław Trentowski, Karol Liebelt, and Joseph Kremer deserve mention. August Cieszkowski has written on philosophical and economic subjects. Moritz Straszewski, the present professor of philosophy at the university of Cracow, has also published some remarkable works.

Mention has already been made of the poetess Elizabeth Druzbacka. Female writers are not very common among Slavonic nations. Perhaps the most celebrated Polish authoress was Klementina Hoffmann, whose maiden name was Tanska, born at Warsaw in 1798. She married Karl Boromäus Hoffmann, and accompanied her husband, in 1831, to Passy near Paris, where she died in 1845. Her novels still enjoy great popularity in Poland. Of the poetesses of later times Gabriele Narzyssa Zmichowska (1825-1878), Maria Ilnicka, translator of Scott's *Lord of the Isles*, and Jadwiga Łuszczewska may be mentioned.

A poet of considerable merit is Adam Asnyk, born in 1838. In his poetry we seem to trace the steps between romanticism and the modern realistic school, such as we see in the Russian poet Nekrasoff. In some of the flights of his Muse he reminds us of Słowacki, in the melody of his verse of Zaleski. Besides showing talent as a poet, he has also written some good plays, as "The Jew" (*Jid*), *Cola di Rienzi*, and *Kiejstut*. Other living poets worthy of mention are Zagorski, Czerwinski, and Maria Konopnicka, who has published two volumes of poems that have been very favourably noticed. Mention must also be made of Bałucki,

born at Cracow in 1837, and Narzymiski (1839-1872), who was educated in France, but spent part of his short life in Cracow, author of some very popular tales.

The four centres of Polish literature, which, in spite of the attempts which have been made to denationalize the country, is fairly active, are Cracow, Posen, Lemberg, and Warsaw. A few years ago a cheap edition of the leading Polish classics, well adapted for dissemination among the people, was published, under the title of *Biblioteka Polska*, at Cracow, which shows a great deal of vitality and is an interesting city. Not only are the professors of its university some of the most eminent living Poles, but it has been chosen as a place of residence by many Polish literary men. The academy of sciences, founded in 1872, celebrated the bicentenary of the raising of the siege of Vienna by Sobieski by publishing the valuable *Acta Joannis III. Regis Poloniarum*. Some good Polish works have been issued at Posen, but it is becoming extremely Germanized, and no part of the original kingdom of Poland has undergone so much change as this. At Lemberg, the capital of Austrian Galicia, there is an active Polish press. Here appeared the *Monumenta Poloniarum Historica* of Bielowski, previously mentioned; but Polish in this province has to struggle with the Red-Russian or Ruthenian, a language or dialect which for all practical purposes is the same as the Southern or Little Russian. At Warsaw, since the last insurrection, the university has become entirely Russianized, and its *Transactions* are published in Russian; but Polish works of merit still issue from the press, —among others the leading Polish literary journal, *Biblioteka Warszawska*. (W. R. M.)

**POLAND, RUSSIAN.** After the three dismemberments of the old kingdom, the name of Poland was chiefly retained by the part of the divided territory annexed to Russia. Since the insurrection of 1863, however, the name "kingdom of Poland" has disappeared. Thenceforward this portion of the Russian empire is referred to in official documents only as the "territory of the Vistula," and later on as the "Vistula governments." Nevertheless the geographical position of Russian Poland, its ethnographical features, its religion, and its traditions differentiate it so widely from the remainder of the Russian empire that the name of Poland still survives in current use. The area of this territory is 49,157 square miles, and the population exceeds 7,300,000. See *RUSSIA*, and map accompanying that article.

Projecting to the west of Russia in a wide semicircle between Prussia and Austria, it is bounded on the N. by the provinces of western and eastern Prussia, on the W. by Posen and Prussian Silesia, on the S. by Galicia, and on the E. by the Russian governments of Volhynia, Vilna, Grodno, and Kovno. It consists for the most part of an undulating plain, 300 to 450 feet above the sea, which joins the lowlands of Brandenburg in the west, and the great plain of central Russia in the east. A low swelling separates it from the Baltic Sea; while in the south it gradually rises to a range of plateaus which imperceptibly blend with the spurs of the Carpathians. These plateaus, with an average height of from 800 to 1000 feet, occupy all the southern part of Poland. They are mostly covered with beautiful forests of oak, beech, and lime, and are deeply cut by the valleys of rivers and numerous streams, some being narrow and craggy, and others broad, with gentle slopes and marshy bottoms. Narrow ravines intersect them in all directions, and their surface often takes, especially in the east, the *puszcza* character,—in other words, that of wild, unpassable, woody, and marshy tracts. In these tracts, which occupy the south-eastern corner of Poland, and are called Podlasie, the neighbourhood of the Polyesie of the Pripet is felt. The Vistula, which borders these plateaus on the south-west, at a height of 700 to 750 feet, has to penetrate them before finding its way to the great plain of Poland, and thence to the Baltic. Its valley divides the hilly tracts of Poland into two parts,—the Lublin heights in the east, and the Sędomierz

(Sandomir), or central, heights in the west. These last are diversified by several ridges which run east-south-east, parallel to the Beskides, the highest of them being those of the "Bald" or "Holy Cross Mountains" (*Łysogórski*, or *Świętokrzyski*), two summits of which respectively reach 1813 and 1961 feet above the sea. Another short ridge, the Chęcinski hills, follows the same direction along the Nida river, reaching 1135 feet at Zamkowa Góra. South of the Nida, the Olkusz Hills, already blended with spurs of the Beskides, fill up the south-west corner of Poland, reaching 1473 feet at Podzamecze, and containing the chief mineral wealth of the country; while a fourth range, from 1000 to 1300 feet high, runs north-west past Częstochowo, separating the Oder from the Warta. In the north, the plain of Poland is bordered by a flat and broad swelling, 600 to 700 feet above the sea, dotted with lakes, and recalling the lake regions of north-western Russia. Its gentle southern slopes occupy the northern parts of Poland, while the province of Suwałki, projecting as a spur towards the north-east, extends over the flat surface of this swelling. Wide tracts covered with sands, marshes, peat-bogs, ponds, and small lakes, among which the streams lazily flow from one marsh to another, the whole being covered with poor pine-forests and a scanty vegetation, with occasional patches of fertile soil—such are the general characters of the northern border-region of the great plains of central Poland.

These plains extend in a broad belt, 150 miles wide, from the Oder to the upper Niemen and the marshes of Pinsk, gently sloping towards the west, and slowly rising towards "the woods" of Volhynia and Grodno. Few hills raise their flat tops above the surface, the irregularities of which for the most part escape the eye, and can be detected only by levellings. As far as the eye can see, it perceives a plain; and each hill, though but a few hundred feet above its surface, is called a "góra" (mountain). The rivers flow in broad, level valleys, only a few hundred or even only a few dozen feet lower than the watersheds; they separate into many branches, enclosing islands, forming creeks, and covering wide tracts of land during inundations. Their basins, especially in the west, are mixed up with one another in the most intricate way, the whole bearing unmistakable traces of having been in recent geological and partly in historical times the bottom of exten-

sive lakes, whose alluvial deposits now yield rich crops. The fertility of the soil and the facility of communication by land and by water have made this plain the very cradle of the Polish nationality, and every furlong of it to the Pole is rich in historical memories. The very name of Poland is derived from it,—Wielkopolska and Wielkopole being the Slavonian for the great plain and its inhabitants.

**Rivers.** Russian Poland belongs mostly, though not entirely, to the basin of the Vistula,—its western parts extending into the upper basin of the Warta, a tributary of the Oder, and its north-east spur (Suwaiki) penetrating into the basin of the Niemen, of which it occupies the left bank. For many centuries, however, the Poles have been driven back from the mouths of their rivers by the German race, maintaining only the middle parts of their basins.

The chief river of Poland, and the very cradle of the Polish nationality, is the Vistula (Pol., *Wisła*), the *Pandalus*, *Vistula*, and *Istula* of antiquity. It has a length of 620 miles, and a drainage area of 72,000 square miles. It rises in Galicia, in the Beskides, 3675 feet above the sea, where the Black and White Vistulas unite. Flowing first north-east, in an elevated valley between the Beskides and the Sandomir heights, it separates Russian Poland from Galicia, and already at Cracow has a breadth of 90 yards. It enters Russian Poland at Zawichost, 473 feet above the sea. After having received the San, it turns north, traversing for some 35 miles a broad valley deeply cut through the plateaus of southern Poland. This valley reaches at several places a width of 10 miles between the limestone crags which border it on both sides, the space between being occupied by two alluvial terraces, where the river winds freely, divides into several branches, and frequently changes its bed. Here it has a speed of 8 feet per second, with a gradient of 1·3 to 1·5 feet per mile, and a depth ranging from 4 to 20 feet. About Jusców (51° N. lat.) it enters the great central plain, where it flows north and west-north-west between low banks, with a breadth of 1000 yards. Its inundations, dangerous even at Cracow, become still more so in the plain, where the accumulations of ice in its lower course obstruct the outflow, or the heavy rains in the Carpathians raise its level. Dams, 20 to 24 feet high, are maintained at great expense by the inhabitants for 60 miles, but they do not always prevent the river from inundating the plains of Opole and Koźienic, the waters sometimes spreading as far as 150 miles to the east. Below Warsaw (267 feet) it frequently changes its bed, so that, for example, Płock (180 feet), which formerly was on its left bank, is now on the right. About Thorn it enters Prussia, and a few miles below this town it finds its way through the Baltic ridge, flowing in a north-east direction and entering the Baltic Sea in the Frische-Haff at Dantzig. On the whole, it is what the physical geographer would call a "young" river, which is still excavating its bed, and probably on this account few towns of importance are situated on the Vistula in Russian Poland, the principal being Sandomierz, Warsaw, and Płock, and the fortresses of Iwangorod and Nowogeorgiënsk (Modlin), while very many small towns have sprung up within short distances from its course. It is navigable almost from Cracow for small boats and rafts, which descend it at high water. Real navigation begins, however, only below its confluence with the Wieprz, the middle and lower Vistula being the chief artery for the traffic of Poland. Thousands of rafts and boats of all descriptions descend every year, with cargoes of corn, wool, timber, and wooden wares, giving occupation to a large number of men. Steamers ply as far as Sandomierz.

The Vistula receives many tributaries, the most important being the San, the Wieprz, and the Bng on the right, and the Nida and the Pilica on the left. The San (220 miles) rises in Galicia, in the same part of the Carpathians as the Dniester, and flows north-west, close to the southern frontier of Poland; it is navigable downwards from Dynów, and is ascended by boats as far as Yarostaw in Galicia. The Wieprz (180 miles) is the chief artery of the Lublin government; it flows north-west past Lublin and Lubartow, joining the Vistula at Iwangorod. It is navigable for small boats and rafts for 105 miles from Krasnostaw. The Bug, which describes a wide curve concentric with those of the middle Vistula and Narew, rises to the east of Lwów (Lemberg) and flows north and west, past Hrubieszów, Chełm, and Brest-Litowski, separating the Polish provinces of Lublin and Siedlce from Volhynia and Grodno. It joins the Vistula a few miles below its confluence with the Narew, some 20 miles below Warsaw, after a course of more than 675 miles. Only light boats (*galary*) are floated down this broad but shallow stream, whose flat and open valley is often inundated. Its great tributary, the Narew (150 miles), brings the forest-lands of Byelovezha into communication with Poland, timber being floated down from Surazh and light boats from Tykocin. The mountain-stream Nida waters the hilly tracts of Kielce, and, rapidly descending south-east, joins the Vistula close by the Opatowiec custom-house. The Pilica rises in the south-western corner of Poland, and flows for 135 miles north and east in a broad, flat, sandy, or marshy valley, of evil repute for its unhealthiness; it joins the Vistula at Mniszew, 30 miles above Warsaw.

The Warta (450 miles) rises in the Czeszow hills, 900 feet above the sea, and flows north and west past Sieradz (448 feet) and Koło. Below Czeszow it waters a flat lowland, whose surface rises only from 2 to 5 feet above the level of the river, and the inhabitants have a constant struggle to keep it to its bed: the country is, however, so low that every spring an immense lake is formed by the river at the mouth of the Ner; as regards its right hand tributaries, it is almost impossible to define them from those of the Bzura, tributary of the Vistula, amidst the marshy grounds where both take their origin. The Warta turns west at Koło and leaves Poland at Pyzdry in the government of Kalisz; it serves to convey timber to Prussia.

The Niemen, which has a total length of 500 miles and a basin of 40,000 square miles, flows along the north-east frontier of Poland, from Grodno to Yurburg, separating it from Lithuania. Already 70 yards wide at Grodno, it advances northwards in great windings, between limestone hills covered with sand, or amidst forests, past numerous ruins of castles, or *koorgans*, which witness the battles that have been fought for its possession. The yellowish sandy plains on its left allow only the cultivation of oats, buckwheat, and some rye. The river flows so slowly below Kovno as to seem almost stationary; it often changes its bed, and, notwithstanding repeated attempts to regulate it, offers great difficulties to navigation. Still, large amounts of corn, wool, and timber are floated down, especially after its junction with the Black Hancza, giving occupation to about 90,000 men. A little above Kovno the Niemen turns west, and after having received the Wilja from the right, it attains a width of nearly 500 yards. At Yurburg it enters eastern Prussia, and reaches the Baltic Sea at the Knische-Haff. Of its tributaries in Poland, only the Hancza Czarna and the Szesupa, which winds through the province of Suwaiki, are worthy of mention.

Lakes are numerous in the province of Suwaiki, amounting there to over five hundred; but the largest of them, Wigry, traversed by the Hancza, covers only 11,000 acres. They are mostly concealed amid thick coniferous or birch forests, and their waters stretch with undefined banks amidst marshes, sands, or layers of boulders thickly covered with moss. Another group of some one hundred and twenty small lakes is situated in the basin of the Warta (north part of Kalisz), the largest being Gopło, 18 miles long and 100 feet deep, surrounded by many smaller lakes, and receiving the Noteć river. It was much larger even within historical times, and was well known from being situated on the highway from the Adriatic, via Koło on the Oder, to the basin of the Vistula.

Though navigable for a few months only, the rivers of Poland have always been of considerable importance for the traffic of the country, and this importance is further increased by several canals connecting them with Russian and German rivers. The Niemen is connected with the Dnieper by the Oginski Canal, situated in the Russian government of Minsk. The Dnieper-and-Bng (Horodecki, Brzeski, also Królewski) Canal in Grodno connects the Mukhavets, tributary of the Bug, with the Pina of the basin of the Pripiet, that is, the Dnieper with the Vistula. The Vistula is connected also with the Oder by the Bydgoski or Bromberg Canal in Prussia, which connects the Brda, of the basin of the Vistula, with the Noteć, or Netze, tributary of the Warta. All these canals are, however, beyond Russian Poland. In Poland proper, the Angustowski Canal connects the Vistula with the Niemen, by means of the Hancza, Netta, Biebrz, and Narew. Another canal, to the west of Łęczyca, connects the Bzura, a tributary of the Vistula, with the Ner and Warta; and the led of the former has recently been altered so as to obtain regular irrigation of the rich meadows extending along its banks.

With the exception of its southern parts, Poland is built up almost exclusively of Secondary and Tertiary formations, covered with a thick sheet of Quaternary deposits. The non-schistous rocks are represented only by a small patch of porphyries near Chęcin, and another of basalts at the castle of Łęczyński. Small deposits of quartzites in the Dyminski Hills, characterized by the *Orthis kielceensis*, Röm., which formerly were considered as Devonian, belong to the Silurian as also a few dolomites appearing from beneath the Devonian Old Red Sandstone and limestones. The last two cover wide tracts in the province of Kielce, and in the district of Będzin, on the Silesian frontier. The Devonian limestones of Kielce, which contain the *Orthis striatula*, *Spirifer inflatus*, *Atrypa reticularis*, *A. desquamata*, *Lepidæna interstitialis*, *Bronteis flabellifer*, *Spirifer verneuili*, and *Rhynchonella cuboides*, thus exhibit a fauna closely akin to that of the Devonian of Germany and Belgium, or the lowest part of the Upper Devonian—the so-called "Cuboides-Schichten." The hard sandstone of Dombrowa, Brzezina, &c., with *Chondes sarcinulata*, *Spirifer paradoxus*, *S. cultrijugatus*, and *Pterinea pailletii*, is certainly Lower Devonian. This formation contains the chief mineral resources of Poland.

The Carboniferous formation appears in the Olkusz and Będzin districts. It consists of sandstones and clays, with layers of coal 30 feet thick. The Permian is represented by porphyritic tuffs in the Olkusz district, "Zechstein" characterized by *Productus hor-*

*ridus*, Sow., at Kielce, and a breccia consisting of Devonian boulders. The Trias is widely spread. It consists of variegated sandstones, characterized by *Myophoria costata*, occurring extensively in the governments of Kielce and Radom, yielding a fine building stone. The red sandstones north and west of Kielce, considered as Permian on Pusch's map, probably belong to the same formation, like the red sandstones in the most northern parts of the Kielce mountains. The "Muschelkalk" appears in the districts of Olkusz and Bedzin, as also in the Kielce mountains, and has great importance, containing as it does zinc, tin, and iron ores. The "Keuper" in the governments of Kielce, Piotrków, and Radom consists of sandstones, dolomites, and limestones, and contains brown coal and iron ores.

The Jurassic formation is widely spread; in south-west Poland it occupies the space from Olkusz to Wielun, and consists of brown and white "Jura," the whitish crags of which give pleasing landscapes at Ojcowo and on the Pilica. The Oolite crags of Ojcowo contain numerous caverns, renowned for their bone deposits, worked out for manure, and for their numerous and remarkable Quaternary fossils. That of Jerzmanowice, close by Ojcowo, the largest of the series, has a length of 750 feet. The Cretaceous formation, which covers very large tracts throughout Poland, consists of lower series of sandstones, and of an upper series containing chalk and limestone, and yielding very fertile marls. They are covered with Tertiary limestones and gypsums, which, together with Cretaceous deposits, cover nearly the whole of the central plain and the northern provinces. The layers of sulphur at Kielce, 7 to 70 feet thick, belong to the Tertiary.

The whole is covered with Quaternary deposits, reaching at several places a very great thickness. They are chiefly made up of boulder clay containing Scandinavian erratics of all sizes up to 5 and 7 feet in diameter. The Baltic ridge is quite covered with them, their southern limit extending to 51° N. lat., or perhaps even to 50°, as the longitudinal valleys of the Kielce hills also contain layers of Scandinavian boulders. Diluvial and alluvial sands and clays cover the glacial deposits; and everywhere in Poland one meets with remains of extensive lakes that filled up all depressions of the country during the post-Glacial period. Thick peat-bogs are being formed in the moister depressions, and cover an aggregate surface of no less than 2,500,000 acres.

In these lacustrine deposits numerous traces of prehistoric man have been found, but the old lake beds still await a more thorough exploration. The bone caves at Ojcowo have yielded rich finds of extinct mammals, thirty-two species of which are familiar to explorers of British caverns; the cave-bear alone has yielded fully four thousand canine teeth, while the mammoth, the woolly rhinoceros, the cave hyæna, and especially the reindeer, are represented by numerous remains. The bones of extinct mammals have been found in association with very numerous relics of man, some of which are most probably Palæolithic, while the great number belong to the Neolithic period,—those cave-inhabitants being in some instances dolichocephalic, like those of the shores of post-Glacial lakes, and in others mesocephalic.

**Minerals.** Southern Poland is rich in minerals, especially in the Kielce mountains and the region adjacent to Prussian Silesia. The Devonian sandstones contain malachite ores at Medziana Góra, near Kielce, and copper has been worked there since the 15th century. In the years 1816–1825 65,009 cwts. of copper ore were extracted, but the mines are now neglected. The brown iron ores, also Devonian, of Kielce, and especially those of Daleszyce, contain no less than 40 per cent. of iron. The Triassic zinc ores of the Olkusz district, more than 50 feet thick at Bolesław, contain 8 to 14 per cent., sometimes 25 per cent., of zinc; and in 1879 2,566,000 cwts. of ore were extracted from nine pits, yielding about 100,000 cwts. of zinc. The tin ores of Olkusz, also Triassic, are still more important, and were extensively wrought as early as the 16th century, notwithstanding the difficulties arising from the presence of water; they are reported to have then yielded more than 35,000 cwts. per annum. In 1878 the very fluctuating yield reached only 5960 cwts. Brown iron ores appearing in the neighbourhood of Bedzin as lenses 55 feet thick, and containing 25 to 33 per cent. of iron, accompany the Triassic zinc ores. Spherosiderites and brown iron ores are also widely spread in the "Keuper." Sulphur is wrought at Czarkowa, in the district of Pińczów; the deposits, which contain 25 per cent. of sulphur, reach a thickness of 7 to 70 feet, and the amount of sulphur is estimated at 1,300,000 cwts.

Carboniferous coal is spread in south-west Poland over a surface of about 200 square miles in the districts of Bedzin and Olkusz, which are estimated to contain 732,000,000 cubic yards of coal. The Triassic brown coal, which appears in the Olkusz district in layers 3 to 7 feet thick, has lately been worked out, the single pit of St John yielding in 1879 204,200 cwts. of coal. Of other mineral produce, chalk exported from Lublin, a few quarries of marble, and many of building stones are worthy of notice. Mineral waters are used medicinally at Ciechoćcin and Natychow.

**Climate.** With the exception of the Łysa Góra hilly tracts (Kielce and South Radom), which lie within the isotherms of 41° and 42°, Poland is

situated between the isotherms of 42° and 46°. The isotherms and isochoims (i.e., lines of equal mean summer and winter temperature) crossing one another at right angles, and the former running east-north-east, Poland is included between the isotherms of 64° and 61° and the isochoims of 35°·7 and 30°·2. The prevailing winds are westerly, with north-north-east and south winds in autumn and winter, and east winds in spring. The number of rainy and snowy days varies from 152 to 158, increasing towards the Baltic, with an average of 21·7 to 23·6 inches of rainfall in central Poland, which figures slowly increase also towards the south on account of the proximity of the Carpathians, where they reach 30·3 inches. Of the above amounts, about 17 per cent. fell in spring, 29 per cent. in summer, 21 per cent. in autumn, and 33 per cent. in winter. Owing to this distribution the snow-covering in Poland is not very thick, and the spring sets in early. Still, frosts lowering the thermometer to -4° and -22° Fahr. are not uncommon, and the rivers are covered with ice for two and a half to three months,—the Warta being under ice for 70 to 80 days, the Vistula at Warsaw for 80 days and (exceptionally) even for 118, and the Niemen for 100 (exceptionally for 140).

The following averages may help to give a more adequate idea of the climate of Poland:—

	Warsaw.	Vilna.
Earliest frost.....	Oct. 18	Oct. 17
Latest frost.....	Mar. 15	Mar. 25
Average maximum temperature.....	85°·7	85°·1
Average minimum do. ....	1°·7	-9°·6
Absolute maximum do. ....	95°·5	89°·3
Absolute minimum do. ....	37°·6	-39°·0
Bright days.....	40	23
Cloudy days.....	154	175
Annual rainfall (total).....	22·8 in.	7·6 in.
Rainfall—November to March.....	6·7 in.	4·7 in.
Prevailing winds in January.....	S.E.	S.
" " in July.....	W.	W.
" " during the year...	S.E.	W.

The flora of Poland is more akin to that of Germany than to that of Russia, several middle European species finding their north-east limits in the basin of the Niemen or in the marshes of Lithuania. Coniferous forests, consisting mostly of pine (*Pinus sylvestris*) and birch, cover large tracts in Mazovia, extending over the Baltic lake-ridge, reaching southwards as far as the junction of the Bug with the Narew, and joining in the south-east the "Polysie" of the Pripiet. The pine covers also the Łysa Góra hills and those on the San. The larch (*Larix europæa*), which three centuries ago covered large tracts, has almost entirely disappeared; it is now met with only in the Samsonowski forests of Sandomeria. The *Pinus Cembra* is only remembered, as also the *Taxus baccata*, which has but a few representatives in Sandomerian forests, on the Pilica, on the *puszczy* of Ostrołęka, and in the Prepy forests on the Niemen. The *Picea obovata* is cultivated.

Of leaf-bearing trees, the common beech (*Fagus sylvatica*) is the most typical of the Polish flora; it extends from the Carpathians to 52° N. lat., and three degrees farther north in small groups or isolated specimens; the confluence of the Bug and Narew may still be regarded as its eastern limit. The white beech (*Carpinus Betulus*), the aspen (*Populus tremula*), and two elms (*Ulmus campestris*, *U. effusa*) are found nearly everywhere, mingled with other trees in forests. The same is true with regard to the lime-tree (*Tilia parvifolia*), which appears in groves only in the east (Niemen, Pripiet, Lublin). It is the most popular tree with the Poles, as the birch with the Russians; judgment of old was pronounced under its shade, and all the folk-lore songs repeat its name. The oak—a highly venerated tree in Poland, though not so much as in Lithuania—grows in forests only on the most fertile patches of land, but it is of common occurrence in conjunction with the beech, elm, &c. The maples (*Acer platanoides* and *A. pseudoplatanus*) are somewhat rare; the black alder (*Alnus glutinosa*) covers the banks of the rivers and canals, and the *Alnus incana* is common. The willow, and the orchard trees—apple, pear, plum, and cherry—are cultivated everywhere.

The flora of Poland contains 12 per cent. of *Compositæ*, 6 per cent. of *Leguminosæ*, 2 per cent. of *Labiata*, 4 per cent. of *Umbellifera*, 5 per cent. of *Crucifera*, and 2 per cent. of *Conifera*.

The wheat frontier coincides very nearly with that of the leaf-bearing forests. It yields good crops on the fertile tracts of Sandomeria and Lublin, and on the plains of the Vistula and Warta, but does not thrive very well beyond 52° N. lat. Rye, oats, barley, buckwheat, and hemp are cultivated everywhere, and flax in the east; hops are very common, and tobacco-culture has been begun in the south. Some attempts in sericulture have been made with success.

The fauna of Poland belongs to the middle European zoological Fauna group; within the historical period it has lost such species as formerly gave it a subarctic character. The reindeer now occurs

*ridus*, Sow., at Kielce, and a breccia consisting of Devonian boulders. The Trias is widely spread. It consists of variegated sandstones, characterized by *Myophoria costata*, occurring extensively in the governments of Kielce and Radom, yielding a fine building stone. The red sandstones north and west of Kielce, considered as Permian on Pusch's map, probably belong to the same formation, like the red sandstones in the most northern parts of the Kielce mountains. The "Muschelkalk" appears in the districts of Olkusz and Będzin, as also in the Kielce mountains, and has great importance, containing as it does zinc, tin, and iron ores. The "Keuper" in the governments of Kielce, Piotrków, and Radom consists of sandstones, dolomites, and limestones, and contains brown coal and iron ores.

The Jurassic formation is widely spread; in south-west Poland it occupies the space from Olkusz to Wielun, and consists of brown and white "Jura," the whitish crags of which give pleasing landscapes at Ojcowo and on the Pilica. The Oolite crags of Ojcowo contain numerous caverns, renowned for their bone deposits, worked out for manure, and for their numerous and remarkable Quaternary fossils. That of Jerzmanowice, close by Ojcowo, the largest of the series, has a length of 750 feet. The Cretaceous formation, which covers very large tracts throughout Poland, consists of lower series of sandstones, and of an upper series containing chalk and limestone, and yielding very fertile marls. They are covered with Tertiary limestones and gypsums, which, together with Cretaceous deposits, cover nearly the whole of the central plain and the northern provinces. The layers of sulphur at Kielce, 7 to 70 feet thick, belong to the Tertiary.

The whole is covered with Quaternary deposits, reaching at several places a very great thickness. They are chiefly made up of boulder clay containing Scandinavian erratics of all sizes up to 5 and 7 feet in diameter. The Baltic ridge is quite covered with them, their southern limit extending to 51° N. lat., or perhaps even to 50°, as the longitudinal valleys of the Kielce hills also contain layers of Scandinavian boulders. Diluvial and alluvial sands and clays cover the glacial deposits; and everywhere in Poland one meets with remains of extensive lakes that filled up all depressions of the country during the post-glacial period. Thick peat-bogs are being formed in the moister depressions, and cover an aggregate surface of no less than 2,800,000 acres.

In these lacustrine deposits numerous traces of prehistoric man have been found, but the old lake beds still await a more thorough exploration. The bone caves at Ojcowo have yielded rich finds of extinct mammals, thirty-two species of which are familiar to explorers of British caverns; the cave-bear alone has yielded fully four thousand canine teeth, while the mammoth, the woolly rhinoceros, the cave hyæna, and especially the reindeer, are represented by numerous remains. The bones of extinct mammals have been found in association with very numerous relics of man, some of which are most probably Paleolithic, while the great number belong to the Neolithic period,—those cave-inhabitants being in some instances dolichocephalic, like those of the shores of post-glacial lakes, and in others mesocephalic.

The flora of Poland is more akin to that of Germany than to that of Russia, several middle European species finding their north-east limits in the basin of the Niemen or in the marshes of Lithuania. Coniferous forests, consisting mostly of pine (*Pinus sylvestris*) and birch, cover large tracts in Mazovia, extending over the Baltic lake-ridge, reaching southwards as far as the junction of the Bug with the Narew, and joining in the south-east the "Polysie" of the Pripiet. The pine covers also the Lysa Góra hills and those on the San. The larch (*Larix europæa*), which three centuries ago covered large tracts, has almost entirely disappeared; it is now met with only in the Samsonowski forests of Sandomeria. The *Pinus Cembra* is only remembered, as also the *Taxus baccata*, which has but a few representatives in Sandomerian forests, on the Pilica, on the *puszczas* of Ostrołęka, and in the Preny forests on the Niemen. The *Picea obovata* is cultivated.

Of leaf-bearing trees, the common beech (*Fagus sylvatica*) is the most typical of the Polish flora; it extends from the Carpathians to 52° N. lat., and three degrees farther north in small groups or isolated specimens; the confluence of the Bug and Narew may still be regarded as its eastern limit. The white beech (*Carpinus Betulus*), the aspen (*Populus tremula*), and two elms (*Ulmus campestris*, *U. effusa*) are found nearly everywhere, mingled with other trees in forests. The same is true with regard to the lime-tree (*Tilia parvifolia*), which appears in groves only in the east (Niemen, Pripiet, Lublin). It is the most popular tree with the Poles, as the birch with the Russians; judgment of old was pronounced under its shade, and all the folk-lore songs repeat its name. The oak—a highly venerated tree in Poland, though not so much as in Lithuania—grows in forests only on the most fertile patches of land, but it is of common occurrence in conjunction with the beech, elm, &c. The maples (*Acer platanoides* and *A. pseudoplatanus*) are somewhat rare; the black alder (*Alnus glutinosa*) covers the banks of the rivers and canals, and the *Alnus incana* is common. The willow, and the orchard trees—apple, pear, plum, and cherry—are cultivated everywhere.

The flora of Poland contains 12 per cent. of *Compositæ*, 6 per cent. of *Leguminosæ*, 2 per cent. of *Labiata*, 4 per cent. of *Umbellifera*, 5 per cent. of *Crucifera*, and 2 per cent. of *Conifera*.

The wheat frontier coincides very nearly with that of the leaf-bearing forests. It yields good crops on the fertile tracts of Sandomeria and Lublin, and on the plains of the Vistula and Wartha, but does not thrive very well beyond 52° N. lat. Rye, oats, barley, buckwheat, and hemp are cultivated everywhere, and flax in the east; hops are very common, and tobacco-culture has been begun in the south. Some attempts in sericulture have been made with success.

The fauna of Poland belongs to the middle European zoological Fauna-group; within the historical period it has lost such species as formerly gave it a subarctic character. The reindeer now occurs

only as a fossil; the sable, mentioned in the annals, has migrated eastwards; the wild horse, also, described by the annals as intermediate between the horse and the ass—probably like the recently discovered *Equus przewalskii*—is said to have been met with in the 13th century in the basin of the Warta, and two centuries later in the forests of Lithuania. The wild goat, bison, and elk have migrated to the Lithuanian forests. The lynx and beaver have also disappeared. The brown bear continues to haunt the forests of the south, but is becoming rarer in Poland; the wolf, the wild boar, and the fox are most common throughout the great plain, as also the hare and several species of *Arvicola*. The mammals in Poland, however, do not exceed fifty species. The avi-fauna, which does not differ from that of central Europe, is represented by some one hundred and twenty species, among which the singing birds (*Dentirostræ* and *Conirostræ*) are the most numerous. On the whole, Poland lies to the westward of the great line of passage of the migratory birds, and is less frequented by them than the steppes of south-west Russia. Still, numerous aquatic birds breed on the waters of the Baltic lake-region.

The population of Poland, 6,193,710 in 1871, reached 7,319,980 in 1881, showing an increase of 1·8 per cent. per annum during the ten years, and an average of 15 persons per square mile. Of these 17 per cent. lived in towns. They were distributed as follows:—

Governments.	Area. Square Miles.	Total Popula- tion, 1881.	Urban Population.	Per Square Mile.
Kalisz.....	4,391	765,403	96,648	17·4
Kielce.....	3,897	622,842	38,493	16·0
Łomża.....	4,667	538,588	51,554	11·5
Lublin.....	6,499	860,382	78,867	13·2
Piotrków.....	4,730	837,928	144,246	17·7
Płock.....	4,200	538,141	78,797	12·8
Radom.....	4,769	633,715	69,058	13·3
Siedlce.....	5,535	616,649	117,011	11·1
Śniatki.....	4,846	603,174	61,827	12·4
Warsaw.....	5,623	1,303,158	465,852	23·2
Total.....	49,157	7,319,980	1,222,553	14·9

The bulk of the population are Poles. During prehistoric times the basin of the Vistula seems to have been inhabited by a dolichocephalic race, different from the brachycephalic Poles of the present day; but from the dawn of history the Slavonians (Poles), mixed to some extent with Lithuanians, are found on the plains of the Vistula and Warta. The purest Polish type is found in the basin of the middle Vistula and in Posen; in the north-east there is a Lithuanian admixture, and in the south-east a Little Russian. The geographical domain of the Poles corresponds approximately with the limits of Russian Poland. Some 250,000 Lithuanians (277,000 or 284,000, according to other enumerations) occupy the north part of Śniatki, their southern limit being the Hancza river and the towns Seino and Śniatki; while the Ruthenians (about 506,000 in 1873) appear in compact masses in the east and south-east, occupying the whole space between the Bug and the Wieprz as far as Siedlce, as also the region between the upper Wieprz and the San. The White Russians numbered 27,000 in the north-east and east, and the Great Russians 12,000. The Poles extend but little beyond the limits of Russian Poland. In east Prussia they occupy the southern slope of the Baltic ridge (the Mazurs); and on the left bank of the lower Vistula they spread to its mouth (the Kaszubes). Westward they occupy a strip of land of an average breadth of 50 miles in Brandenburg, Posen, and Silesia, stretching down the Warta as far as to Birnbaum (100 miles east of Berlin); and in the south they extend along the right bank of the Vistula in western Galicia to the San. In Russia they constitute, with Jews, Lithuanians, Ruthenians, and White Russians, the town population, as also the landed nobility and *szlachta*, in several provinces west of the Dwina and the Dnieper. Their numbers in these provinces may be seen from the following figures:—

Governments.	Population (1867).	Number of Poles.	Percentage of Poles.	Probable Number of Poles in 1881.
Vilna.....	973,570	143,290	14·7	175,000
Podolia.....	1,946,760	233,650	12·0	269,000
Volhynia.....	1,643,270	172,405	10·5	215,000
Minsk.....	1,185,590	117,750	10·4	160,500
Grodno.....	958,850	89,850	9·3	112,700
Vitebsk.....	838,050	40,725	4·9	54,950

According to the localities which they inhabit, the Poles take different names. They are called Wielkopolsanie on the plains of middle Poland, while the name of Małopolsanie is reserved for those on the Warta. The name of Łęczykanie is given to the inhabitants of the marshes of the Ner, that of Kurpie to those of the Podlasie; Knjawiacy, Szlęcy in Silesia, and Górale in the Carpathians.

The Kaszubes, and especially the Mazurs, may be considered as separate stocks of the Polish family. The Mazurs (whose northern limits may be thus described—Przerosl in Śniatki, Goldap, Rastenburg, and Bischofsburg in Prussia, and Miawa in Płock) are distinguished from the Poles by their lower stature, broad shoulders, and massive structure, and still more by their national dress, which has nothing of the smartness of that of the southern Poles, and by their ancient customs; they have also a dialect of their own, containing many words now obsolete in Poland, and several grammatical forms bearing witness to the Lithuanian influence. They submit without difficulty to German influence, and already are Lutherans in Prussia. The language of the Kaszubes can also be considered as a separate dialect. The Poles proper are on the whole of medium stature (5 feet 4·6 inches), finely built, dark in the south and fair in the north, richly endowed by nature, inclined to deeds of heroism, but perhaps deficient in that energy which characterizes the northern races of Europe, and in that sense of unity which has been the strength of their present rulers.

The German element is annually increasing both in number and in influence, especially during the last twenty years. The Łódź manufacturing district, the Polish Birmingham, is becoming more German than Polish; and throughout the provinces west of the Vistula German immigration is going on at a steadily increasing rate, especially in the governments of Płock, Kalisz, Piotrków, and Warsaw. It is estimated that a strip of land 35 miles wide along the Prussian frontier is already in the hands of Germans, whose advance is further favoured by the rapid transference of landed property into German hands in Posen. In Russian Poland associations of four to six men, supported by German banks, purchase large numbers of properties belonging to members of the Polish nobility who have been ruined since the last insurrection. No fewer than 30,736 German landholders, owning 5433 estates, were enumerated last year in the provinces west of the Vistula; while 13,714 foreign proprietors, farmers, and labourers (11,497 Prussians and 1914 Austrians) were at the same time owners of 1,857,900 acres, valued at 135,000,000 roubles. According to other statistics, the foreigners in Poland, mostly Germans, who remained foreign subjects, numbered 170,000 in 1881 (5·15 per cent. of the population). Of these, 91,440 (families included) hold landed property to the amount of 2,605,500 acres, or 8·3 per cent. of the area of the kingdom. The aggregate number of Germans in Russian Poland, estimated at 370,000 in 1873, must now exceed 450,000, thus constituting about one-fifteenth of the population.

The Jews, who are found everywhere throughout Poland, are still more numerous, and must now exceed a million. They are nowhere agricultural; in the larger towns many of them are artisans, but in the villages they are almost exclusively engaged as shopkeepers, second-hand traders, dealers on commission, innkeepers, and usurers. In the country, both commerce and agriculture are in the hands of their intimately connected trading associations. Their relations with Poles and Ruthenians are anything but cordial, and "Jew-baiting" is of frequent occurrence. They are increasing much more rapidly than the Slavs.

The relative numbers of the various inhabitants of Poland may be seen from the following figures:—

	According to Galkin (1868).	According to Rittich (1873).	Per cent.
Poles.....	3,900,580	4,375,640	68·4
Jews.....	764,950	860,330	13·4
Little Russians.....	428,380	505,960	8·5
White Russians.....	33,520	26,665	
Great Russians.....	11,065	12,155	
Germans.....	234,150	370,360	5·8
Lithuanians.....	277,050	241,150	3·8

The prevalent religion is the Roman Catholic, to which, in 1870, Religion. 4,596,956 out of a population of 6,034,430 belonged; at the same date 246,485 were adherents of the United Church, 327,845 were Lutherans, 34,135 were of the Greek Church, and 4926 Nonconformists. The Jews at the same date were reckoned (certainly an under-estimate) at 815,443, and the Mohammedans at 426. The number of followers of the United Church has much diminished since 1873, when they were compelled to join the Greek Church.

Since the last insurrection a series of measures have been taken to reduce the numbers of the Roman Catholic clergy in Poland; in 1883 there remained 1313 churches out of 1401, 1544 priests out of 2322, 10 monasteries out of 29, and 8 convents out of 30. One diocese (Podlasie) having been abolished, and a new one established

at Kielce, while several bishops had been sent out of the country, the whole situation remained unsettled until 1883, when the pope recognized the new diocesan subdivisions introduced by the Russian Government. Poland is now divided into four dioceses (Warsaw, Sandomierz, Lublin, and Plock).

**Agri- culture.** From remote antiquity Poland has been celebrated for the production and export of grain. Both, however, greatly declined in the 18th century; and towards the beginning of this century the peasants, ruined by their proprietors, or abandoned to the Jews, were in a more wretched state than even their Russian neighbours. Serfdom was abolished in 1807; but the liberated peasants received no allotments of land, and a subsequent law (1808) rendered even their transference from one landlord to another almost impossible; the old patrimonial jurisdictions were also retained. Compelled to accept the conditions imposed by the landlords, they had to pay rack-rents and to give compulsory labour in various forms for the use of land. Only a limited number were considered as permanent farmers, while nearly one-half of the peasants became mere *proletaires*; in 1864 1,328,830 former peasants had ceased to have land rights at all. Pursuing a policy intended to reconcile the peasantry to Russian rule and to break the power of the Polish nobility, the Russian Government promulgated, during the outbreak in 1864, a law by which those peasants who were holders of land on estates belonging to private persons, institutions (such as monasteries and the like), or the crown were recognized as proprietors of the soil,—the state paying compensation to the landlords in bonds, and the peasants having to pay a yearly annuity to the state until the debt thus contracted had been cleared. The valuation of these allotments was made at a rate much more advantageous than in Russia, and the average size of holding reached 15 acres per family. Of those who held no land a number received it out of the confiscated estates of the nobility and monasteries. At the same time the self-government of the peasant was organized on democratic principles. The so-called "servitudes," however, that is, the right to pasture on and take wood from the landlord's estates, were maintained for political reasons, becoming a source of great inconvenience both to landlords and peasants.

Whatever be the opinion held as to the intention of these reforms, there can be no doubt that they resulted in a temporary increase of prosperity, or at any rate an alleviation of the previous misery of the peasants. In 1864 there were 342,500 peasant families, holding an aggregate of 8,300,000 acres of land; but only 22,000 peasants, that is, less than one-half per cent. of the agricultural population, were proprietors, the remainder (218,500) being nobles, while 2,000,000 peasants were *czaszewiki*, that is, tenants at will, and 1,338,000 had no land at all. In 1872 there were already 572,100 free peasant estates, occupying 13,000,000 acres. In ten years (1864-73) the area of cultivated soil had increased by 1,350,000 acres, while during the fourteen years 1845-59 its increase was only 540,000 acres. The crops, which stood in 1846-60 at an average of 9,360,000 quarters of corn and 6,500,000 quarters of potatoes, reached respectively 15,120,000 and 14,400,000 quarters. The yearly increase, which was only 2.2 per cent. for corn and 1.3 per cent. for potatoes during the years 1846-60, became respectively 4.7 and 8.3 per cent. during the years 1864-75, and the average crop per head rose from 1.93 quarters in 1850 to 2.52 in 1872. The annual increase of horses, which formerly was 1 per cent., reached 2.7 per cent. in 1864-70, while the yearly increase of cattle remained almost stationary (1.2 per cent., against 1.1 per cent.). In fact, Poland had in 1870 only 37 head of cattle for each 100 persons, against 41 head in 1860. Another consequence of these measures was a notable decrease of crime, and a rapid increase of village primary schools, maintained by the peasants themselves.

It must be acknowledged, however, that the maintenance of the "servitudes" has become a serious evil. Moreover, the want of pasture-land, the want of money for improvements, quite insufficiently supplied by the joint-stock banks in the villages, and the very rapid increase in the price of land, from 50 roubles per morgen (1.3335 acre) to 120 and 250 roubles, have all helped to lessen the benefits of the agrarian measures of 1864. The peasants are unable to purchase land proportionately with the increase of population; and, while a few of them buy, many others are compelled to sell to the Jews (notwithstanding the law which prohibits the purchase of land by Jews) or to German immigrants. The estates of the nobility do not pass into the hands of the Polish peasants as they are sold, and still less to Russians, but largely into those of German immigrants.

Agriculture in Poland is carried on with more perfect methods on the whole than in Russia. The extensive cultivation of beet-root, of potatoes for distilleries, and of grasses has led to the introduction of a rotation of several years instead of the former "three-fields" system; and agricultural machinery is in more general use, especially on the larger estates of the west. Winter wheat is extensively cultivated, especially in the south, the Sandomir wheat having a wide repute. In 1873 50 per cent. (15,728,000

acres) of the surface of Poland was under crops, 9 per cent. (2,929,000 acres) under meadows, and 26 per cent. (8,242,000 acres) under forests. The first of these figures exceeds now 54 per cent. In 1881 the crops reached 19,050,000 quarters of corn, 21,151,000 quarters of potatoes, and 14,368,000 cwts. of beetroot (14,365,950 cwts. in 1882). The corn crops were distributed as follows:—wheat, 11 per cent.; rye, 38; oats, 29; barley, 12; buckwheat, 4; various, 6 per cent.,—3 per cent. being used for manufactures, 22 per cent. for seed, 60 per cent. for home consumption, and 15 per cent. for export. The potatoes were used almost entirely for distilleries. The culture of tobacco is successfully carried on (about 3500 acres), especially in Warsaw, Plock, and Lublin.

Cattle rearing is an important source of income. In 1881 there were approximately 3,300,000 cattle, 4,500,000 sheep (including 2,500,000 of the finer breeds), and 1,000,000 horses. Fine breeds of horses and cattle occur on the larger estates of the nobility, and cattle are exported to Austria. Bee-keeping is widely spread, especially in the south-east. Fishing is carried on remuneratively, especially on the Vistula and its tributaries.

Manufactures have shown a rapid increase during the last twenty years. While in 1864 the annual production was only 50,000,000 roubles, it now exceeds 150,000,000,—the manufactures of Poland yielding one-eighth of the total production of the Russian empire.

Mining has shown a still more rapid development within the same period. While in 1862 only 154,100 cwts. of pig-iron and 100,900 cwts. of iron and steel were made, these figures respectively reached 947,800 and 1,742,500 cwts. in 1881; and, whereas the highest figure in the annual returns of the coal-mining industry from 1867 to 1873 was only 2,494,000 cwts., the average for 1876-80 was 17,157,000, and the amount reached 27,659,000 cwts. in 1881. The zinc mines yielded in 1881 89,640 cwts., and the extraction of tin reached 7580 cwts. in 1878. Sulphur was obtained to the amount of 6450 cwts. in 1879.

The development of the leading manufactures may be seen from the following figures:—

	1866.		1874.	
	Produce in Roubles.	Hands.	Produce in Roubles.	Hands.
Woolen stuffs.....	7,134,463	7,579	26,833,000	12,716
Linen and hemp stuffs.....	1,151,382	6,669	2,294,000	6,900
Cottons.....	6,099,474	9,578	22,492,000	16,949
Silks.....	61,785	100	533,000	350
Preparation, dyeing, hats.....	606,656	165	4,318,000	906
Paper wares.....	587,552	1,083	1,843,000	1,289
Produce from wood.....	311,126	379	2,665,000	2,497
Animal produce.....	4,150,756	5,579	8,572,000	3,182
Mineral produce.....	1,591,833	5,583	4,169,000	7,096
Metallic wares.....	5,654,496	7,149	9,426,000	7,899
Chemical produce.....	443,980	368	900,000	443
Total.....	27,793,523	44,232	88,845,000	60,227
Average production per hand.....	628	...	1,375	...

Thus, while the number of hands occupied in these industries has increased by 40 per cent., the production has nearly trebled, showing a corresponding improvement in the machinery employed. The chief manufacturing centres are the Łódź region in the government of Piotrków (woollen stuffs, cottons, sugar, corn-flour, wine-spirit, coal-mines) and Warsaw (linen stuffs, leather, machinery, sugar, wine-spirit, tobacco, and all kinds of grocery and mercery wares). Mining is chiefly concentrated in the south-west. The annual production for separate governments (exclusive of mining, flour-mills, and breweries, and the number of hands employed by distilleries remaining unknown) was given in 1879 as follows:—

	Roubles.	Hands.
Piotrków.....	60,900,000	36,550
Warsaw.....	42,110,000	37,605
Kalisz.....	14,670,000	9,159
Lublin.....	10,495,000	5,577
Łomża.....	4,543,000	581
Kielce.....	2,919,000	2,337
Radom.....	2,121,000	1,708
Plock.....	2,109,000	1,747
Siedlce.....	1,862,000	1,815
Suwałki.....	684,000	403
Total.....	142,413,000	97,482
Russia in Europe.....	1,102,949,000	711,097

These figures, however, have already increased considerably, especially with regard to distilleries, which yielded, in 1852-53, 6,252,500 gallons of pure alcohol; while the sugar-works, which occupied in 1852-53 5774 men, 2536 women, and 2403 children, produced 315,460 cwts. of rough sugar and 425,800 cwts. of refined sugar. In 1852 the production reached 69,221,769 roubles in Piotrkow, 3,945,200 in Silesia, and 1,240,230 in Suwalki.

The railways of Poland have an aggregate length of 555 miles. A line of great importance, connecting Vienna with St. Petersburg, crosses the country from south-west to north-east, passing through the mining district and Warsaw, and sending a short branch to Elbl. Another important line, connecting Danzig with Odessa, crosses Poland from north-west to south-east. A branch line, parallel to this last, connects Skiernewice with Thorn and Bromberg; while a military railway connects the fortresses of Warsaw and Ivangorod with Brest-Litowsky, via Si-dlice and Lukow, and a side line will soon connect Siedlitz with Mafidin on the lower Bug. The great line from Berlin to St. Petersburg crosses North Suwalki for 54 miles, between Eydikunen and Korno. The aggregate length of the interlaminated roads, increased by 2110 miles since 1854, is now about 6700 miles.

The traffic on the Polish railways is very brisk. In 1859 the aggregate amount of merchandise brought to and sent from Warsaw reached respectively 25,053,699 and 15,245,699 cwts.; and the whole amount of merchandise conveyed on Polish railways within Poland (exclusive of the Eydikunen and Korno line), amounted to 81,462,699 cwts.

The chief custom-houses of the Russian empire—Wierzbikowo, Sosnowice, Granica, Warsaw—and many minor ones are situated on the frontiers of Poland. Their aggregate imports and exports reached respectively 127,414,654 and 140,320,221 roubles in 1852.

The "primary cell" of the administrative organization of Poland is the *gmina*,—formerly a village community for the common possession and partly also for the common cultivation of land, which lost its character with the introduction of serfdom, but has been taken by the law of 1864 as the basis of the organization of the peasantry in Poland. Each district is subdivided into twelve to twenty *gminas*, including several villages and all farms on its territory, and having a population of from 2000 to 10,000 inhabitants. All landholders of the *gmina* who are in possession of at least 4 acres constitute the communal assembly of the *gmina*. Only the clergymen and the police officials are excluded from it. Each member has but one vote, however extensive his property. The *gmina* differs thus from the Russian *mir* in its including, not only peasants, but also all landed proprietors of the territory. The assembly elects the *voiv*, or elder (the executive of the *gmina*), a clerk, a *voiv* in each village, and a tribunal consisting of *voiv*s, who judge all matters of minor importance, according to local customs. It also allocates the taxation among the members of the *gmina*, administers the common property (pasture, grazing lands, forests, &c.), has charge of the poor, and generally deals with all questions educational, hygienic, and economic which concern the *gmina*. The cost of administration of each *gmina* varies from 1000 to 3000 roubles. In reality, the powers of the *gmina* are, however, very much limited in all but purely economical questions by a numerous bureaucracy, and especially by the "chief of the district" nominated by the crown; there is also a general tendency towards transforming it into a mere auxiliary to the Russian administration, the clerk or secretary becoming its chief organ.

The provincial administration is regulated by the law of December 31, 1855. Each government being subdivided into ten to twelve districts, the district administration consists of an *owczodziej* *natchalnik*, or "chief of the district," with a number of secretaries and a "chancellerie" (military, for recruiting; philanthropic; for mutual assurance against fire; for finance; and for gendarmerie). The provincial administration, under a military governor, consists in each of the ten governments of the following institutions:—(1) "chancellerie" of the governor; (2) a provincial "college," with councillors corresponding to the following departments—administration, military and police, finance, state domains, law, medicine, and insurance; (3) a philanthropic committee; (4) a postal department; (5) a "college" for finance; (6-10) departments of excise, customs, forests, control, and education. There is also in each government a special institution for the affairs of peasants.

The entire administration of Poland is under the governor-general, residing at Warsaw, whose power is limited only by "collegiate" institutions corresponding to the different branches of administration. He is at the same time the commander of the entire military force of the "Warsaw military district." Justice is represented by the *gmina* tribunals; the justices of the peace (nominated by government); the *voiv*, or "court" of the justices of the peace; the district tribunals (*assizes*) in each government; and the Warsaw courts of appeal and cassation. The prisons of Poland, with exception of a reformatory for boys at Srodzieniec, are in a very bad state. With an aggregate capacity for only 4650 prisoners, they had in 1853 7210 inmates. Poland constitutes also a separate educational district, a district of roads and communications, an administration of justice district, and two mining districts.

Poland has had no separate budget since 1857; its income and expenses expenditure are included in those of the empire, and since 1851 they have ceased to appear under separate heads. The peasants' arrears, which reached 653,655 in 1858, have notably increased since then, ranging from 269,600 to 600,000 roubles in each government.

Perhaps no other country in Europe had so many towns (453), Municipal for the most part enjoying municipal rights according to the Magdeburg and Lithuanian law, as Poland. A large number of them (225) remained, however, private property, or property of the crown. In some of them the proprietors only levied rents on the holders of land that had been built upon; while in others the *dominium supremum* was maintained, and the proprietor exacted, not only rents, but also taxes from the inhabitants and visitors, claiming also the monopoly of selling spirits, &c.

After the last insurrection, all towns with less than 2000 inhabitants were deprived of their municipal rights, and were included, under the designation of *posadz*, in the *gminas*. The seigniorial rights were abolished or redeemed, and those inhabitants who lived on agriculture received allotments of land redeemed by the state. But the spirit-selling monopoly was maintained, as also the "servitudes." Viewed with suspicion by the Russian Government, the Polish towns received no self-government like the villages. Instead of the former elective municipal councils (which enjoyed *de jure* very large rights, including that of keeping their own police, while in reality they were under the rule of the nobility), Russian officials were nominated and entrusted with all the rights of the former municipal councils. These last were, however, maintained to carry out the orders of the military chiefs. The new municipal law of 1870, first introduced at Warsaw and then applied to other towns, reduced the functions of the municipal council almost to nothing, depriving it even of the right of discussing the general budget, which is established by a special administrative committee aided by three to four citizens nominated by the governor. The burgomaster, chosen by Government out of three candidates, and the members of the municipality (*tsurniki*) elected by one section of the citizens, mostly from the poorest classes, have no authority. The burgomaster, who often is a retired private soldier, very badly paid (£18 to £45 per year), is entirely dependent upon the police and the chief of the district, and has to discharge all sorts of functions (bailliff, policeman, &c.) which have nothing to do with municipal affairs.

Poland naturally contains the first line of the fortifications of the Russian empire on its western frontier. These fortifications, *trassees*, however, are intended only to protect the country to the east of the Vistula, the region to the west of it, which contains the chief mining and manufacturing districts of Poland, remaining quite open to invasion. The marshy lowlands, covered with forests on the western bank of the Vistula, are a natural defence against an army advancing from the west, and they are supported by the fortresses on the Vistula connected by the Vistula railway. Their centre is at Warsaw, with Novogeorgievsk, formerly Modlin, in the north, at the mouth of the Bug, and Ivangorod, formerly Demblin, in the south, at the mouth of the Wieprz. Novogeorgievsk is a strongly fortified camp, which requires a garrison of 12,000 men, and may shelter an army of 50,000 men. The town Sierock, at the junction of the Bug and Narew, is now fortified to protect the rear of Novogeorgievsk.

The citadel of Warsaw protects the railway bridge over the Vistula, and six forts—rather out of date, however—protect the capital. The fortress of Ivangorod, on the right bank of the Vistula, is now supported by six forts, four of which are situated on the right bank and two on the left. The Vistula line of fortresses has, however, the great disadvantage of being easily taken from the rear by armies advancing from East Prussia or Galicia. Brest-Litowsky, at the western issue from the marshes of the Pripiet, the towns of Dubno and Lutsk, now about to be fortified, and Bobruisk constitute the second line of defence.

The educational institutions of Poland are represented by a University with 1600 students in 1851; 18 gymnasiums and 8 provincial gymnasiums for boys, with 8262 scholars in 1878; 3 "real-schulen," with 914 scholars; and 3279 primary schools, with 113,054 boys and 57,220 girls. There are also excellent technical schools, an institute of agriculture and forestry at Nova-Alexandrya, and several seminaries for teachers. In 1851 the number of scholars was 1 to 35 of the aggregate population, only 19 per cent. of the children of school age receiving instruction in school. The Jewish children mostly are taught in the *heder*, where they receive almost no instruction at all.

The school is the great means used by the Russian Government "Russification" of Poland. The teaching in the *sektion*—former *Szkola Główna*, now the university of Warsaw (even that of Polish literature), has been carried on in Russian since 1873, both by a few Polish professors and by the new Russian ones. Polish is taught in primary and secondary schools only twice a week, in the lower classes; and the scholars are prohibited from speaking Polish within the walls of the lycées. In all official communications Russian is obligatory, and a gradual elimination of Poles from the

administration is steadily going on, Polish employes being either limited in number (to a fourth, for instance, for the examining magistrates), or else totally excluded from certain administrations (such as that of certain railways). The vexatious measures of Russian rule keep up a continuous feeling of discontent; and, though it was allowed in 1864 that the agrarian measures would conciliate the mass of the peasantry with the Russian Government, it now appears that the peasants, while gaining in those feelings of self-respect and independence which were formerly impossible to them, are not accommodating themselves to Russian rule; the national feeling is rising into activity with them as formerly with the *szlachta*, and it grows every day.

Towns.

There are 27 towns the population of which exceeded 10,000 inhabitants in 1880-82, and 66 towns having a population of more than 5000. The list of the former is as follows:—Warsaw (1882), 406,250; Augustow, 11,100; Biala, 19,450; Czestochowa, 15,520; Garwolin, 14,620; Kalisz, 16,400; Kalwarya, 10,610; Kielce, 10,050; Konska Wola, 14,300; Kutno, 13,210; Lask, 10,810; Lodz, 49,590; Lomza, 15,000; Lublin, 34,930; Lukow, 11,030; Mlawa, 10,010; Piotrkow, 23,050; Plock (1883), 19,640; Radom (1883), 12,870; Sedomierz, 14,080; Siedlce, 12,320; Sieradz, 15,040; Suwalki, 18,640; Turek, 11,500; Wloctawek, 20,660; Wlodawa, 17,980; Zgorz, 13,360.

(P. A. K.)

**POLARITY AND ENANTIOMORPHISM.** Any figure, such as a solid of revolution, which has one line in it in reference to which the figure is symmetrical may be said to have an axis, and the points at which the axis cuts the surface of the figure are poles. But the term polarity when applied to material figures or substances is usually confined to cases where there are not only a definite axis and poles, but where the two poles have distinct characters which enable us to recognize them and say which is which. It is in this sense that the word is used here.

Two figures or two portions of matter are said to be *enantiomorph* to each other when these forms are not superposable, i.e., the one will not fit into a mould which fits the other, but the one is identical in form with the mirror image of the other.

**Polarity.**—As examples of polarity we may take an awn of barley or a cat's tail, in which we recognize the distinction between the two poles or ends, which we may call A and B by finding that it is easy to stroke from say A to B but not in the opposite direction. As an example of enantiomorphism we may take our two hands, which will not fit the same mould or glove, but the one of which resembles in figure the mirror image of the other.

It will be seen by and by that there is a close relation between polarity and enantiomorphism.

In the examples of polarity just given the condition occurs because the parts of the body are arranged in the direction of the axis in a particular order which is different when read backwards. The simplest expression for such a state of matters will be found in the case of a substance composed of equal numbers of three different kinds of particles, these particles being arranged along the axis in the order

A | *abcabc* . . . . . *abc* | B,

where A and B are poles and *a*, *b*, *c* particles of three different kinds. Of course the same may occur with a more complicated constitution, the condition being that the cyclical order read from A to B is different from that read from B to A. Even with particles all of the same kind we can imagine this sort of polarity produced by such an arrangement as

A | *aaaaa* *aaaaa* *aaaaa* *aaaaa* | B,

where the density varies periodically as we pass along the axis, but so that the order of variation is different in passing from A to B and from B to A. There is another sort of polarity produced also by an arrangement such as that described above, but here not along the axis but about it. As we took a cat's tail as an example of the one, so we may take a sable muff as an example of the other. As we stroke the tail in one direction along the axis, so

we stroke the muff in one sense about the axis. This arrangement also produces polarity, for there is a real difference between the two ends of the muff. The one is that into which we put our right hand, the other that into which we put our left hand if the fur is to lie downwards in front. If we reverse the ends we find the fur sticking up in front, and we have thus as little difficulty in distinguishing the two poles from one another in this as in the former sort of polarity.

We can easily imagine the particles of a compound substance to be arranged so as to produce this polarity. To take a simple case,—the molecules of the substance may be formed of three atoms *a*, *b*, and *c*, arranged  $a \begin{smallmatrix} b \\ c \end{smallmatrix}$  with the planes of the molecules all at right angles to the axis, so that on turning the substance about the axis in one sense the atoms in every molecule follow each other in the order *abc*, and of course in the opposite order when the rotation is reversed.

In these examples the polarity is due to an arrangement of the matter at rest, but both kinds of polarity may be produced by motion. Thus a rotating body has polarity of the second kind; the axis is the axis of rotation, and the two poles differ from each other as the two ends of a muff do. A wire along which a current of electricity is passing has polarity of the first kind; and a magnet, in which currents of electricity may be supposed to circulate about the axis, has polarity of the second kind.

There is an important difference between these two kinds of polarity. We have seen that they depend on two different conditions—the one on an arrangement of matter or motion along the axis, the other on a similar arrangement about the axis. This gives rise to a difference in their relation to their mirror image.

If we hang up a cat's tail by one end, say the A end, in front of a mirror, we see in the mirror the image of a cat's tail hanging by its A end. But if we hang up a muff by one end, say the right-hand end, before a mirror, we see in the mirror the image of a muff hanging by its left-hand end. If we put our hands into the muff in the usual way and stand before the mirror we see a person with his hands in a muff in the usual way. But his right and left hands correspond to our left and right hands respectively, and the right and left ends of the muff in the mirror are the images of the left and right ends respectively of the real muff. Thus the mirror image of a body having polarity of the second kind has its polarity reversed.

But the muff and its image are not truly enantiomorph. They differ in position but in nothing else. Turn the one round and it will fit the other.

Magnetic and electric polarity having been already discussed under ELECTRICITY and MAGNETISM, we shall here consider some cases of crystalline polarity.

Both kinds of polarity occur in crystals.

We have no direct means of ascertaining how the ultimate particles of a crystal are arranged, but it seems reasonable to suppose that there is a relation between the form of the crystal and the structure of its smallest parts; and, when we find the crystals of particular substances always showing polarity of the one or the other kind, we naturally suspect that this is the external indication of such an arrangement of the particles as has been shown above to be capable of producing structural polarity. Of crystalline polarity of the first kind the most striking instances are tourmaline and electric calamine (hydrated silicate of zinc), forms of which are shown in figs. 1 and 2, in which it will be seen that the crystals are not similarly terminated at the two ends. It is this kind of crystalline polarity (often called "hemimorphism") which (as was first observed by Haüy and more fully investigated by

Gustav Rose and by Hankel) is associated with pyroelectricity (see MINERALOGY, vol. xvi. p. 376). It is worthy of

FIG. 1.—Tourmaline.

FIG. 2.—Electric Calamine.

note that the crystalline polarity and the physical (electric) polarity occurring in the same substances are both of the kind not inverted by reflexion in a mirror.

As an instance of the same kind of crystalline polarity of a somewhat more complicated character, also associated with pyroelectricity, we may take boracite. The crystals of this mineral exhibit combinations of the cube, the rhombic dodecahedron, and the tetrahedron, as shown in fig. 3. If four lines are drawn corresponding to the four diagonals of the cube, it will be observed that at the two ends of each of these axes the crystal is differently developed. (In the figure one of these axes is indicated by the dotted line.) These axes, therefore, resemble the single axis in tourmaline and electric calamine, and are also axes of pyroelectricity, the end at which the tetrahedral face is situated being the antipolar pole.<sup>1</sup>

FIG. 3.—Boracite.

Scheelite, apatite, ilmenite, and fergusonite are examples

FIG. 4.—Ilmenite.

FIG. 5.—Apatite.

of crystalline polarity of the second kind. Figs. 4, 5, and 6 are representations of forms of ilmenite, apatite, and fergusonite.

Crystalline polarity of both kinds no doubt depends on the arrangement of the molecules and on their structure; it manifests itself by the occurrence of hemihedral or hemimorphic forms. A crystal may have a polar structure although these external marks of polarity are absent, just as the faces parallel to planes of cleavage do not appear on every crystal.

Another kind of contrast between the two complementary hemihedral forms of the same substance may be mentioned here.

FIG. 6.—Fergusonite.

<sup>1</sup> Upon some crystals of boracite the faces of both tetrahedra occur. They can, however, be easily distinguished from one another. The faces of the tetrahedron represented in the figure are smooth and shining, while those of the opposite tetrahedron are rough and usually much smaller. It has been suggested that boracite is only apparently regular, and that each crystal is really a group of eight pyramids with their apices in the centre of the group. For a full discussion of the relation between pyroelectricity and crystalline form the reader is referred to a series of papers by Professor Hankel in *Trans. R. Soc. Sci. of Sciences*, 1857-72.

Marbach observed that different specimens of iron pyrites (and also of cobalt glance) have very different thermoelectric characters, differing indeed from one another more than bismuth and antimony. Gustav Rose showed that these thermoelectrically opposite kinds are also crystallographically opposite. There is indeed no geometrical difference between two opposite hemihedral forms in the regular system, but Rose detected a difference in the lustre and striation of the faces of the two kinds, and by examining the rare cases in which the two opposite pentagonal dodecahedra or tetragonal icositetrahedra occur on the same crystal proved that the one surface character belongs to the one, the other surface character to the other of the two complementary hemihedra.

**Enantiomorphism.**—A figure having polarity of the first kind gives a mirror image resembling itself in form and in position; a figure having polarity of the second kind gives a mirror image resembling itself in form but not in position—the poles being inverted. A figure the axis of which has both kinds of polarity will therefore give a mirror image not superposable to the figure itself, because the polarity of the second kind is reversed while that of the first kind remains unchanged. The figure and its mirror image are enantiomorph, as well as polar. We can construct a figure which is enantiomorph to its mirror image but not polar.

Imagine a muff so made that in one half the fur lies the one way, and the opposite way in the other half (fig. 7, where the arrow-heads indicate the lie of the fur). In whichever way we put our hands into this muff one end will be wrong; the muff in the figure has, in fact, two right-hand ends. It has therefore no polarity; the two ends are exactly alike. But there are two ways in which such a non-polar muff could be made—with two right-hand ends as in the figure, or with two left-hand ends, and these two forms are enantiomorph. A helix or screw has similar properties (compare fig. 8 with fig. 7); if uniform it is non-polar, but is either right- or left-handed. Hence the property which each of two enantiomorph bodies possesses has been called by Sir William Thomson "helical asymmetry."

FIG. 7.

FIG. 8.

As we have crystals exhibiting polarity of both kinds, so we have also enantiomorph crystals, indeed the word enantiomorph was first used by Naumann to express the relation between such crystals. The crystallographic theory of enantiomorph crystals has been very fully worked out. We may divide them into two groups—(1) those in which the helical asymmetry depends on the presence of tetartohedral forms of the regular or of the hexagonal system, and (2) those in which it depends on the presence of hemihedral forms of the rhombic system or hemimorphic forms of the monoclinic system.

In the first group the asymmetry seems to be produced by the manner in which the molecules, themselves symmetrical, are arranged in the crystal. In the second group the molecules themselves appear to have helical asymmetry. This is shown by the action of these substances on polarized light. We shall take examples from each group. If we allow a solution of sodium chlorate to crystallize we find that the crystals, which belong to the regular system, are of two kinds enantiomorph to each other. These are represented in fig. 9. The enantiomorphism depends on the combination of the tetrahedron

and the pentagonal dodecahedron.<sup>1</sup> Now when a ray of plane polarized light is passed through one of these crystals the plane of polarization is rotated, the amount of rotation being proportional to the length of the path in

Fig. 9.—Sodium Chlorate. *a*, right-handed; *b*, left-handed.

the crystal. The crystals having the form *a* rotate to the right, those having the form *b* to the left. They are therefore optically as well as crystallographically enantiomorph. But a solution of sodium chlorate is without action on the plane of polarization, even if the solution be made by dissolving only right-handed or only left-handed crystals, and if a crystal be fused the fused mass is optically inactive, so that it would seem that the optical activity depends on the arrangement of the molecules in the crystal and not on any enantiomorphism in the molecules. The enantiomorphism of quartz crystals is indicated by the presence of faces of a tetartohedral form (vol. xvi. p. 389). The two kinds of crystals rotate the plane of polarization equally, but in opposite senses, when a plane polarized ray is passed through a section cut at right angles to the axis of the crystal. Here also the optical activity ceases when crystalline structure is destroyed by fusion or solution.

Right-handed and left-handed tartaric acids crystallize in enantiomorph forms (fig. 10). Their solutions are optically

Fig. 10.—Tartaric Acid. *a*, right-handed; *b*, left-handed.

ally active, the amount of the rotation for the same strength of solution and the same length of path in it being the same in both acids, but the sense of the rotation is right-handed in the one and left-handed in the other. It is clear that here we have to do with enantiomorph molecules. In ordinary physical properties such as density, solubility, refracting power—in short, in everything *not involving right- or left-handedness*—the acids are identical. When mixed in equal proportions they unite and form racemic acid which is optically inactive, and from racemic acid we can by various means recover unchanged the right and left-handed tartaric acids. We now know a considerable number of cases where, as in that of the two tartaric acids, both enantiomorphs have been discovered, and many where only one has as yet been found.

It is natural that we should ask what peculiarity of constitution can give a molecule this helicoidal asymmetry? A very ingenious answer to this question was given simultaneously and independently by the French chemist Le Bel and the Dutch chemist Van't Hoff. We shall

<sup>1</sup> This combination is regarded as tetartohedral because the tetrahedron and the pentagonal dodecahedron belong to two different classes of hemihedral forms.

give a short statement of the essential points of this interesting theory.

All the known substances which are optically active in solution are compounds of carbon, and may be regarded as derived from marsh gas, a compound of one atom of carbon and four of hydrogen, by the replacement of hydrogen by other elements or compound radicals. Now we do not know how the atoms of hydrogen are actually arranged relatively to each other and to the atom of carbon in the molecule of marsh gas, but, if we may make a supposition on the subject, the most simple is to imagine the four hydrogen atoms at the apices of a regular tetrahedron in the centre of which is the carbon atom as in the diagrams (fig. 11), where *C* represents the position of the carbon atom and *a*, *β*, *γ*, *δ* that of the four atoms of hydrogen.

If these hydrogen atoms are replaced

Fig. 11.

by atoms of other elements or by compound radicals we should expect a change of form of the tetrahedron. If two or more of the atoms or radicals united to the carbon atom are similar there is only one way of arranging them, but if they are all different there are two ways in which they may be arranged, as indicated in the figures. It will be seen that these two arrangements are enantiomorph. In the figures the tetrahedron is represented as regular, but if the distance from *C* depends on the nature of the atom, the tetrahedron, when *a*, *β*, *γ*, and *δ* are all different, will not be symmetrical, but its two forms will be enantiomorph. A carbon atom combined with four different atoms or compound radicals may therefore be called an asymmetric carbon atom.

Now all substances of ascertained constitution, the solutions of which are optically active, contain an asymmetric carbon atom, and their molecules should therefore, on the above hypothesis, have helicoidal asymmetry.

The converse is not generally true. Many substances contain an asymmetric carbon atom but are optically inactive. It is easy to reconcile this with the theory; indeed, a little consideration will show that it is a necessary consequence of it.

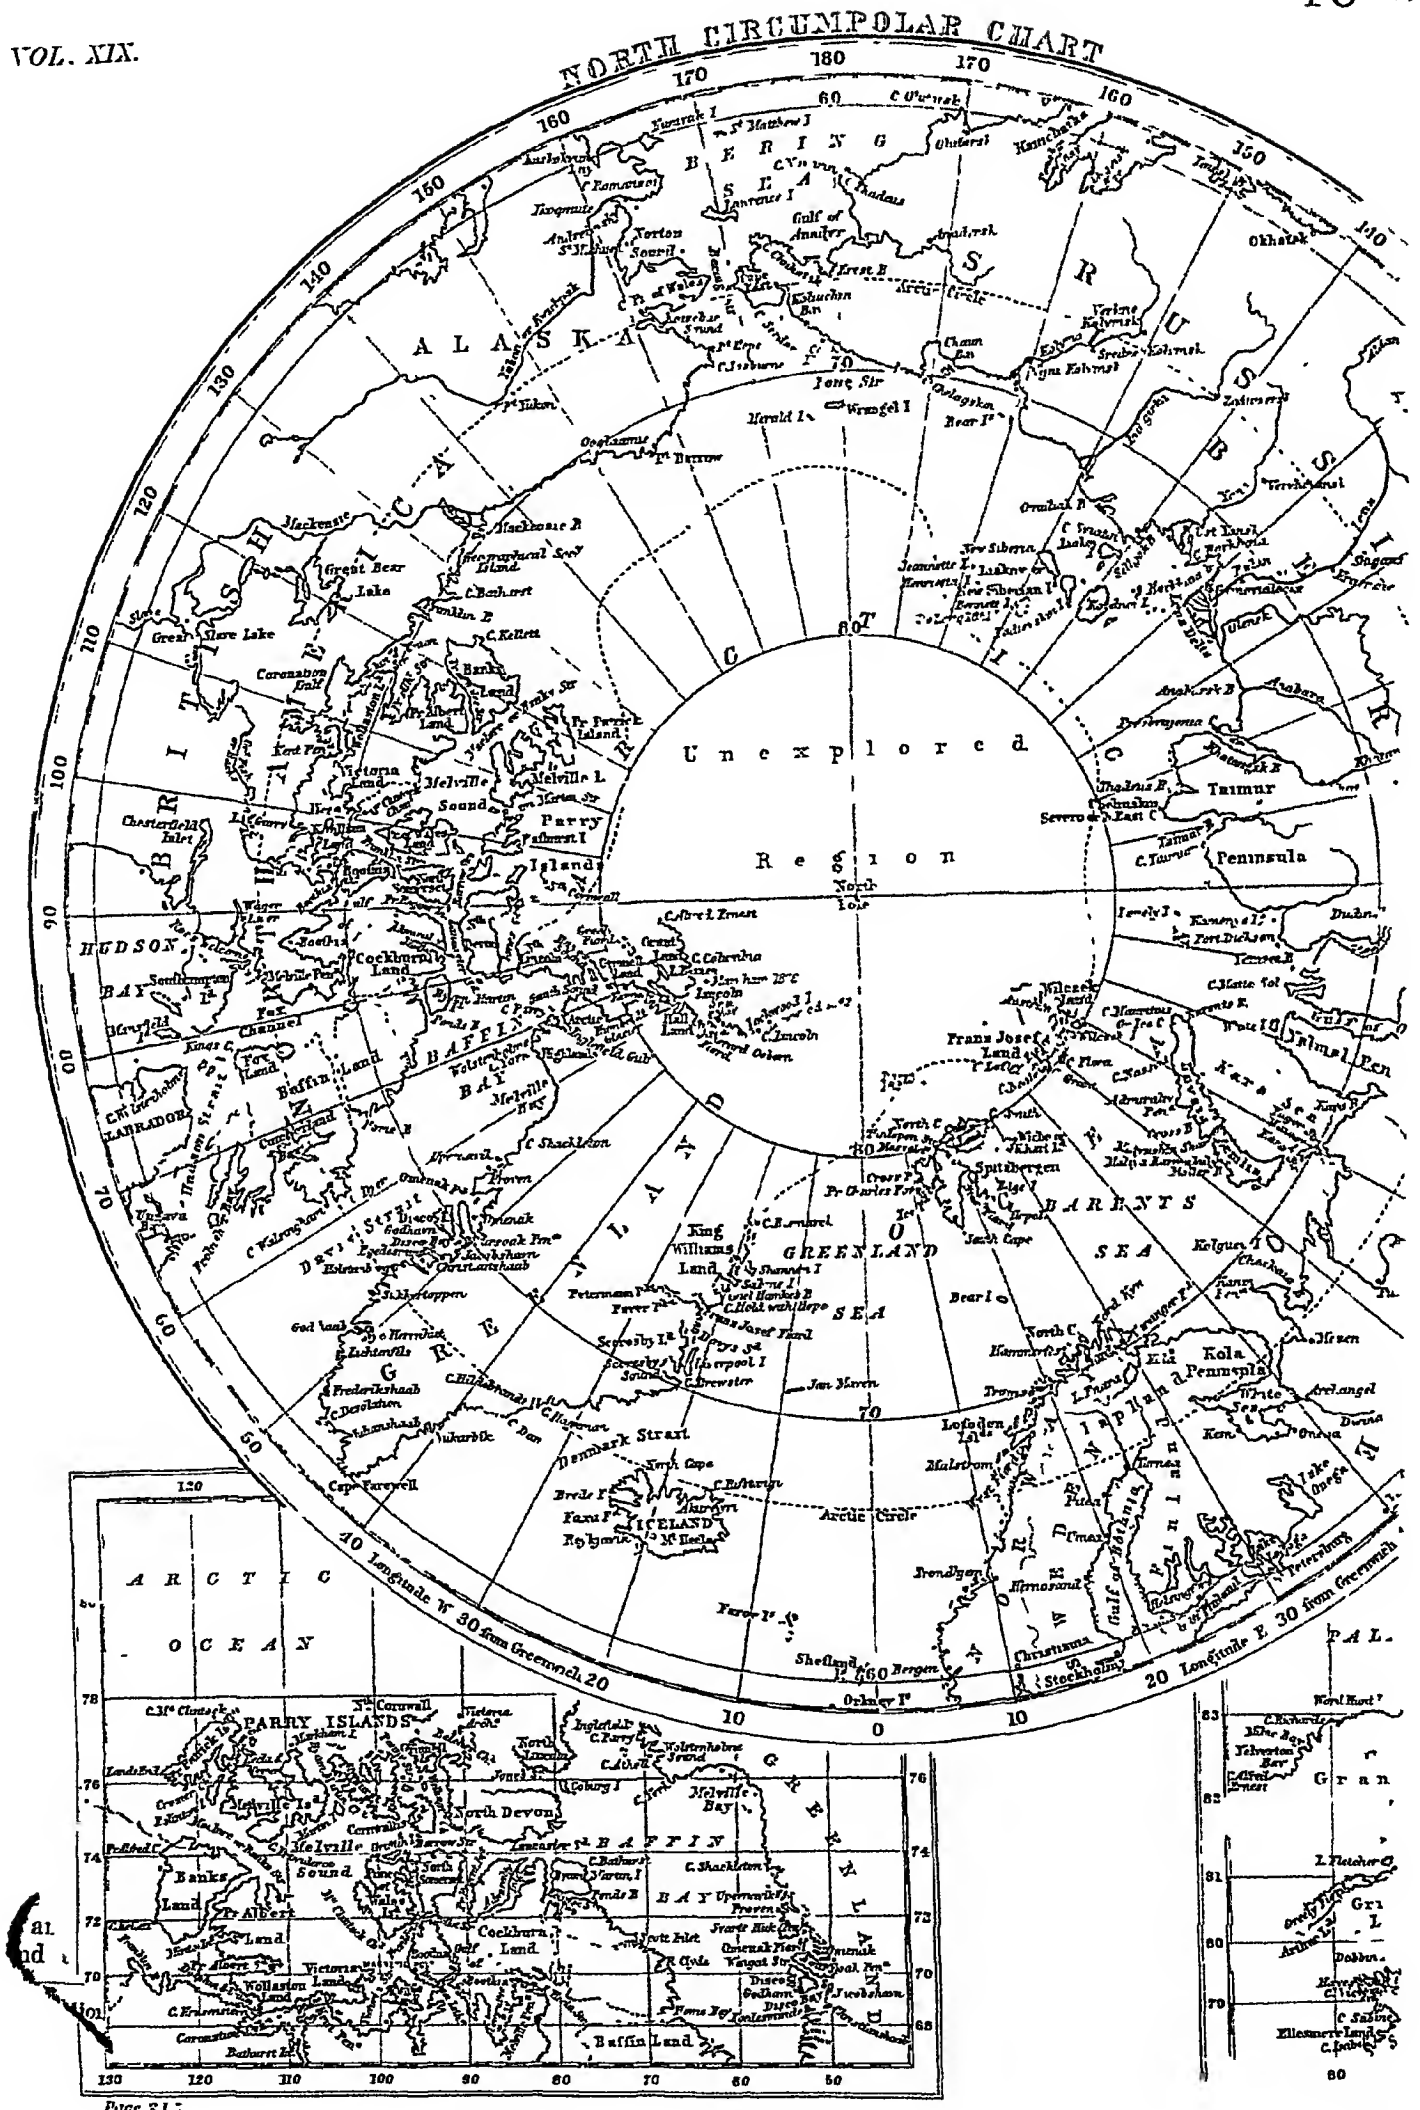

Let us suppose that we have the symmetrical combination of *C* with *a*, *a*, *β*, *γ* and that we treat the substance in such a way that one *a* is replaced by *δ*. The new arrangement is asymmetrical, and will be right or left as the one or the other *a* is replaced. But the chances for the two are equal, and therefore, as the number of molecules in any quantity we can deal with is very great, the ratio of the number of right-handed molecules in the new substance to the number of left-handed ones will be sensibly that of unity. It is therefore evident that by ordinary chemical processes we cannot expect to produce optically active from optically inactive substances; all that we can get is an inactive mixture of equal quantities of the two oppositely active substances.

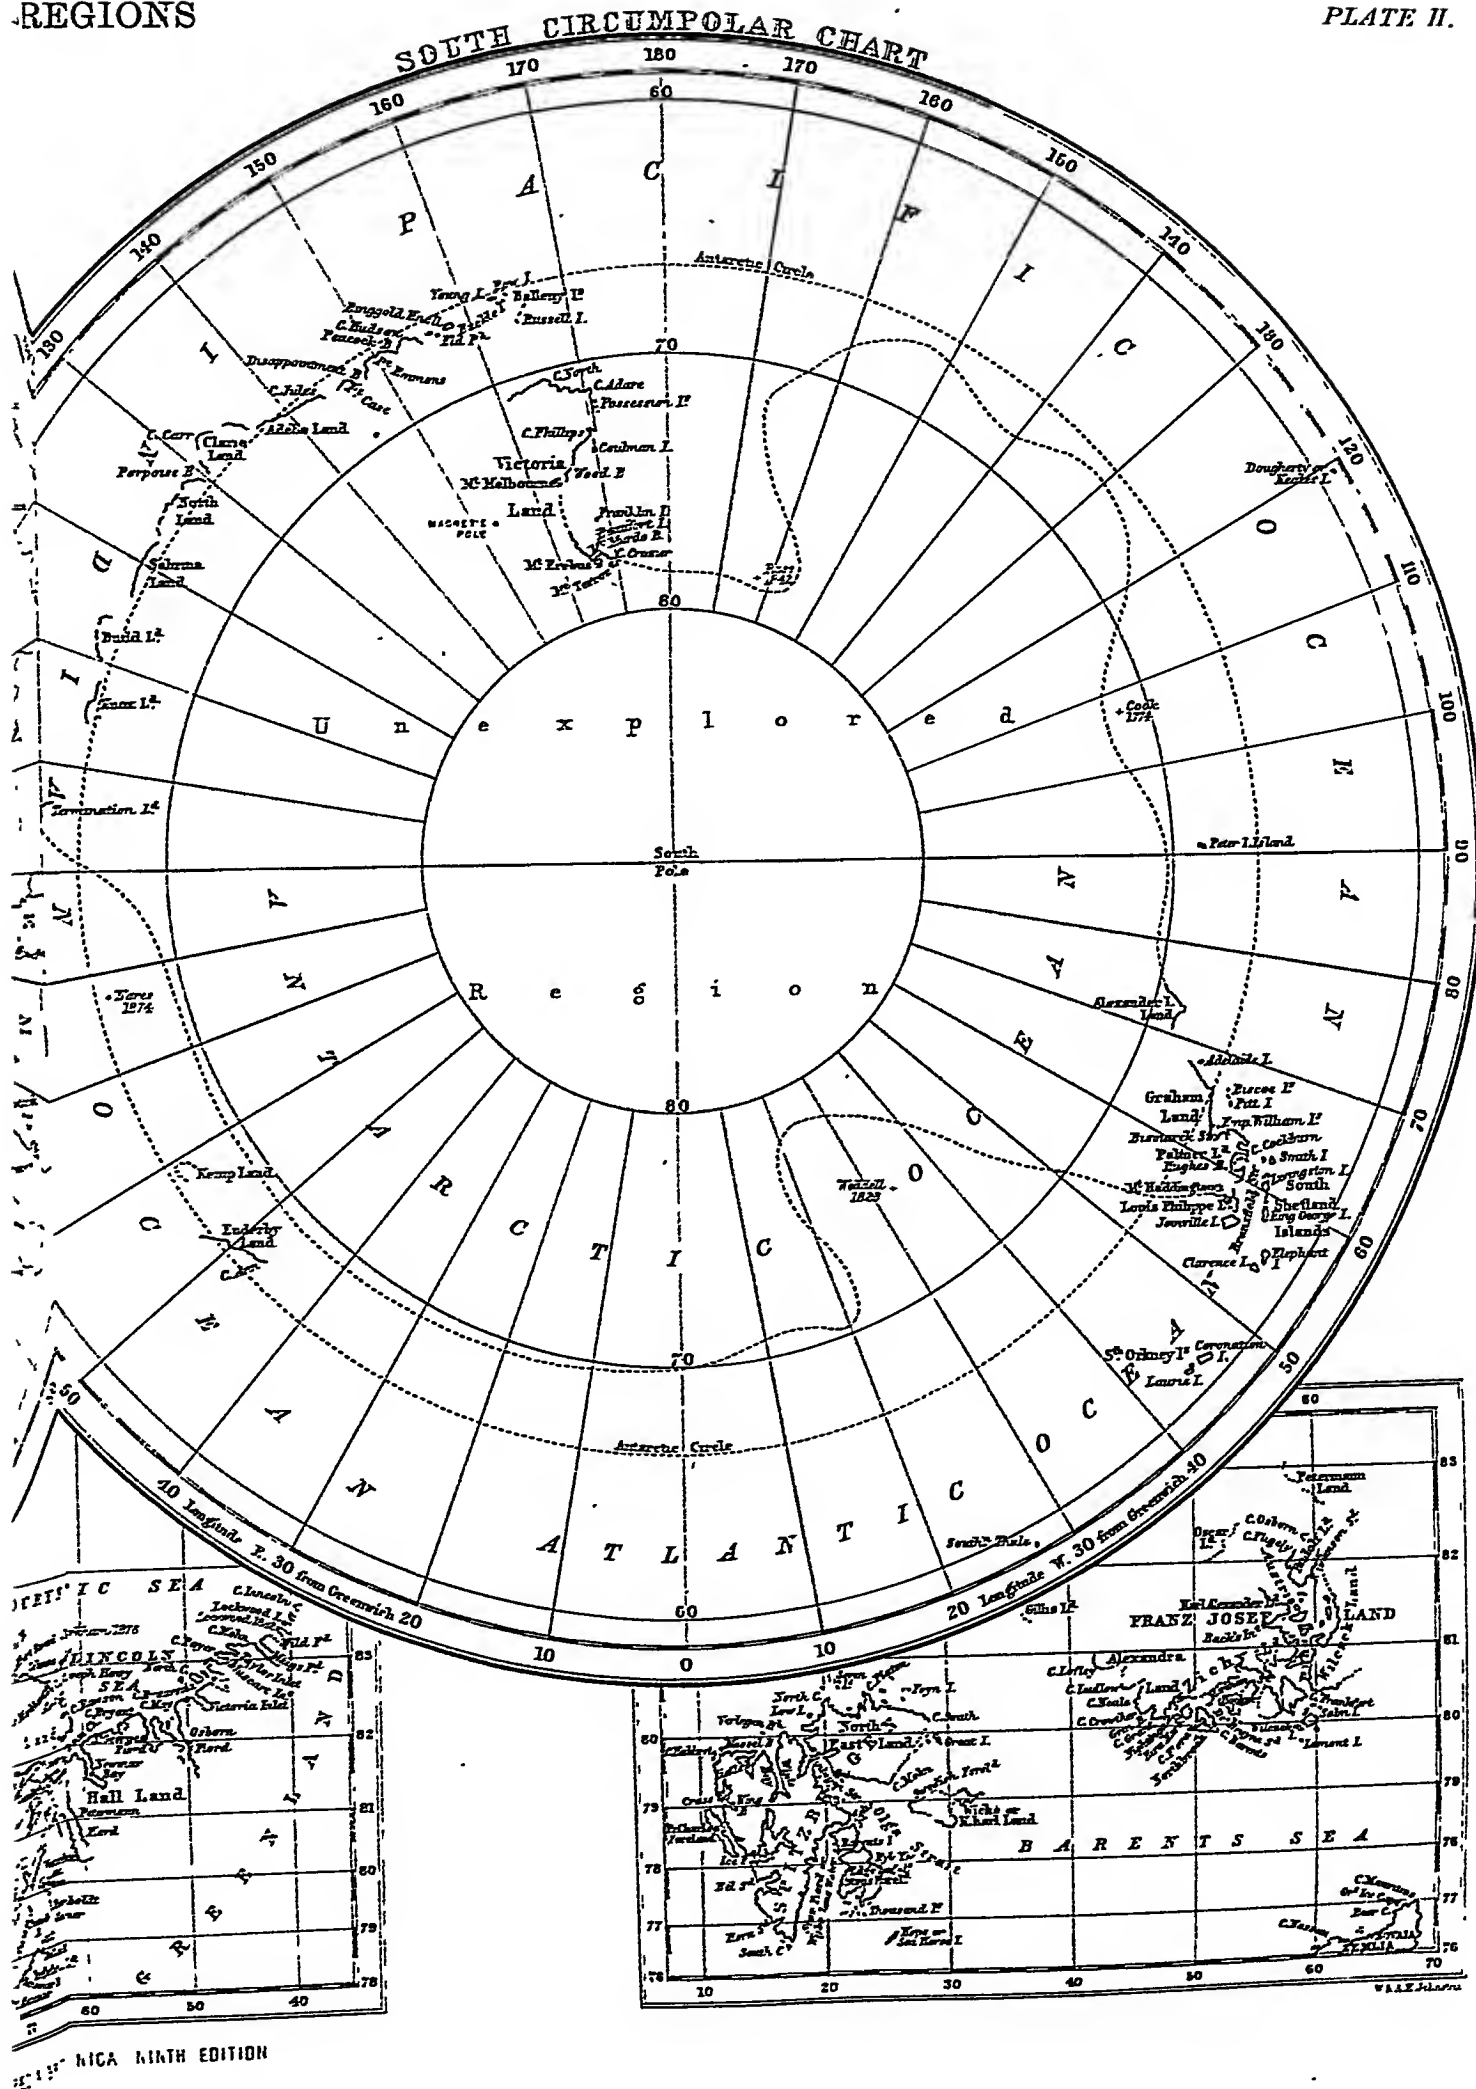

As these two substances have identical properties in every respect where right- or left-handedness is not involved, the problem of separating them is a difficult one. We may note three distinct ways in which the separation can be effected.

(1) By crystallization. For example, the right and left double tartrates of soda and ammonia crystallize in enantiomorph forms (fig. 12) and are less soluble in water than the double racemate formed by their union. If therefore racemic acid (the optically inactive compound of equal quantities of right and left tartaric acids) is half neutral-

ized with soda and half with ammonia, we obtain an optically inactive solution containing a mixture of the two double salts. If this solution is allowed to crystallize each salt crystallizes independently, and the crystals can be separated by picking them out. Further, a supersaturated solution of the one double salt is not made to crystallize by contact with a crystal of the other, so that

FIG. 12.—Double Tartrate of Soda and Ammonia. *a*, right-handed; *b*, left-handed.

if we make a supersaturated solution of the inactive mixture and drop into the vessel, at different places, two crystals one of the right the other of the left salt, crystallization occurs at each place, at the one of the one kind and at the other of the other.

(2) By the action of another optically active substance. While the salts of the two opposite tartaric acids with an inactive base are precisely alike in solubility, density, and other physical characters, and, if they crystallize, crystallize in the same form (or in enantiomorph forms), it is not at all so when the base is optically active; thus right tartaric acid forms a crystalline salt with left asparagine, while with the same base left tartaric acid gives an uncrystallizable compound.

(3) By the action of living ferments. The minute fungi which act as ferments do not show any right- or left-handedness as far as their obvious anatomical structure is concerned, but Pasteur has shown that some of them are, if we may use the expression, physiologically asymmetrical. As an example we may give the very interesting case of mandelic acid. This acid, which stands to benzoic aldehyde (bitter almond oil) in the same relation as lactic acid does to common aldehyde, contains one asymmetric carbon atom in its molecule. It is optically inactive, and therefore, if Le Bel and Van 't Hoff's theory is true, it must be a mixture of two oppositely active acids. Now Lewkowitsch found that when *Penicillium glaucum* is cultivated in

a solution of mandelic acid fermentation takes place. This goes on until exactly half of the acid is decomposed, and what remains has all the properties of mandelic acid, but is optically active; it is the right-handed component of the mixture, the growing fungus having consumed the other.

There is an interesting peculiarity of tartaric acid discovered by Pasteur (to whom we owe nearly all our knowledge of the relations between optical activity and crystalline form in tartaric acid) which is of importance in connexion with the theory we have just been explaining.

We have not only right and left tartaric acid and racemic acid, the inactive compound of the two, but also a kind of tartaric acid which is inactive but incapable of being separated into the two oppositely active acids.

Now the chemical formula of tartaric acid is

It will be observed that the carbon atoms marked \* are asymmetric, and that they occupy precisely similar positions in the molecule. Each of them is combined with H, OH, COOH and CH(OH)COOH. If in both of them these four things are arranged in the same order there is helicoidal asymmetry—the one order giving the one, the other the other enantiomorph form. But if the one has one order and the other the opposite, then there is in the whole molecule no helicoidal asymmetry, as the two halves exactly balance one another. There is not, as in racemic acid, a compound of one molecule of each of the two opposite active acids, but rather a compound of half a molecule of each, and we should not expect such a compound to be easily separable. Jungfleisch has shown that if any one of the four tartaric acids (right, left, racemic, and inactive) is mixed with a little water and kept for some time at a temperature of about 200° C., it is converted into a mixture of racemic and inactive tartaric acids, so that, as racemic acid can be divided into right and left tartaric acids, it is possible to prepare any one of the four from any other. (A. C. B.)

POLARIZATION OF LIGHT. See LIGHT and WAVE THEORY.

## POLAR REGIONS

Plate II. THE polar regions extend respectively from the Arctic and Antarctic Circles, in 66° 32' N. and S., to the north and south poles, the circles being 1408 geographical miles from the poles. The intense cold and the difficulties of ice navigation have made the discovery and examination of these regions a slow and hazardous task. Millions of square miles are still entirely unknown. In the present article the history of the progress of discovery within the north polar region will be traced, and some account of its physical geography will follow. A similar review of work in the south polar region will conclude the article.

### NORTH POLAR REGION.

**Extent.** The Arctic Circle is a ring running a little south of the northern shores of America, Asia, and Europe, so that those shores form a fringe within the polar region, and are its boundary to the south, except at three openings,—those of the North Atlantic, of Davis Strait, and of Behring's (more properly Bering's) Strait.

**Approaches.** The width of the approach to this region by the Atlantic Ocean, in its narrowest part, is 660 miles, from the Norwegian Islands of Lofoten to Cape Hodgson on the

east coast of Greenland. The width of the approach by Davis Strait in the narrowest part, which is nearly on the Arctic Circle, is 165 miles; and the width of Behring Strait is 45 miles. Thus out of the whole ring of 8640 miles along which the Arctic Circle passes about 900 miles is over water. This great environment of land is an important feature in the physical condition of the north polar region. It influences the currents and the movements of ice, which are still further affected by the archipelagos lying to the northward of the fringing coast-lines. The larger opening into the north polar region by way of the Atlantic is divided from Davis Strait by the vast mass of Greenland, which, extending for an unknown distance to the north, crosses the Arctic Circle and ends in a point at Cape Farewell in 59° 48' N. lat. It was inevitable that the routes across the Arctic Circle by the Atlantic and Davis Strait should first become known, because these openings to the polar regions are nearest to the temperate regions inhabited by the exploring nations of Europe.

A rumour respecting Thule, an island on the Arctic Circle, first brought by Pytheas (q.v.), and afterwards doubted, was the extent of the knowledge of the north

polar regions with which the ancients can be credited. But in the 9th century some Irish monks really appear to have visited Iceland. The monk Dicuil, writing about 825, says that he had information from brethren who had been at Thule during several months, and they reported that there was no darkness at the summer solstice.

Other. King Alfred told the story of the first polar voyages undertaken for discovery and the acquisition of knowledge, in his very free translation of Orosius. In the first book he inserted the narrative of the voyages of Other and Wulfstan, related to him by the former explorer himself. The localities mentioned in the story cannot now be identified, but it seems probable that Other rounded the North Cape, and visited the coast of Lapland.

Norsemen. The Norsemen of the Scandinavian peninsula, after colonizing Iceland, were the first to make permanent settlements on the shores of Greenland, and to extend their voyages beyond the Arctic circle along the western coast of that vast glacier-covered land. See GREENLAND. The Norse colonies in Greenland at Brattelid and Einarsfjord did not extend farther north than 65°, but in the summer time the settlers carried on their seal hunting far beyond the Arctic circle. One of their runic stones was found in a cairn in latitude 73° N., the inscription showing that the date of its being left there was 1235. Another expedition is believed, on good grounds, to have reached a latitude of 75° 46' N. in Barrow Strait, about the year 1266. Their ordinary hunting grounds were in 73° N., to the north of the modern Danish settlement of Upernivik. For the visits of the Greenlanders to the American coasts see AMERICA, vol. i. p. 706.

The last trace of communication between Greenland and Norway was in 1347. The black death broke out in Norway and the far off colony was forgotten; while the settlers were attacked by Skrellings or Eskimo, who overran the West Bygd in 1349. Ivar Bardsen, the steward to the bishopric of Gardar in the East Bygd, and a native of Greenland, was sent to convey help to the sister colony. A document, of which Ivar Bardsen was the author, has been preserved. It consists of sailing directions for reaching the colony from Iceland, and a chorography of the colony itself. It is the oldest work on arctic geography, and is still valuable in the study of all questions relating to the early settlements in Greenland. From 1400 to 1448 there was some communication, at long intervals, with the Greenland settlers, but during the latter half of that century it entirely ceased. Here then the ancient portion of polar history comes to an end. The next period, comprised in the 16th and 17th centuries, was that in which expeditions were despatched across the Arctic Circle to discover a shorter route to India.

Willoughby. Sebastian Cabot, whose own northern voyages have been spoken of in the article CABOT, was the chief promoter of the expedition which sailed under Sir Hugh Willoughby and Richard Chancellor on the 20th May 1553, "for the search and discovery of the northern parts of the world, to open a way and passage to our men, for travel to new and unknown kingdoms." Willoughby, after discovering Nova Zembla (Novaya Zemlya) by sighting the coast of Goose Land, resolved to winter in a harbour of Lapland, where he and all his men perished of starvation and cold. Chancellor reached the Bay of St Nicholas, and landed near Archangel, which was then only a castle. He undertook a journey to Moscow, made arrangements for commercial intercourse with Russia, and returned safely. His success proved the practical utility of polar voyages. It led to a charter being granted to the Association of Merchant Adventurers, of which Cabot was named governor for life, and gave fresh impulse to arctic discovery.

Burrough. In the spring of 1556 Stephen Burrough, who had

served with Chancellor, sailed in a small pinnace called the "Searchthrift," and kept a careful journal of his voyage. He went to Archangel, and discovered the strait leading into the Kara Sea, between Nova Zembla and the island of Waigat. In May 1580 the company fitted out two vessels under Arthur Pet and Charles Jackman, with Pet orders to pass through the strait discovered by Burrough, and thence to sail eastward beyond the mouth of the river Obi. Pet discovered the strait into the Kara Sea, between Waigat and the mainland, and made a persevering effort to push eastward, returning to England in safety. Jackman, after wintering in a Norwegian port, sailed homeward but was never heard of again.

In 1558 a narrative and map were published at Venice The Zenl. which profoundly affected the system of polar cartography for many years afterwards. The publication was the handiwork of a Venetian nobleman named Niccolò Zeno. Towards the close of the 14th century his ancestor, also named Niccolò, made a voyage into the northern seas, and entered the service of a chief named Zichni as pilot. He was eventually joined by his brother Antonio, and four years afterwards died in the country he called Frislanda. Antonio remained ten years longer in the service of Zichni, and then returned to Venice. The younger Niccolò found the mutilated letters of these brothers in the Zeni palace, with a map; and out of these materials he prepared the narrative and map which he published, adding what he considered improvements to the map. It was accepted at the time as a work of high authority, and the names on it continued to appear on subsequent maps for at least a century, puzzling both geographers at home and explorers in the field. After a very exhaustive study of the subject, Mr Major has identified the names on the Zeni map, as follows:—Engronelant, Greenland; Islanda, Iceland; Estland, Shetlands; Frisland, Faroe Isles;<sup>1</sup> Markland, Nova Scotia; Estotiland, Newfoundland; Drogeo, coast of North America; Icaria, coast of Kerry in Ireland.

We now come to the voyages of Frobisher, undertaken Frobisher. to obtain the means for equipping an expedition for the discovery of a shorter route to India by the north-west. Aided by Michael Lok, an influential merchant and diligent student of geography, Frobisher sailed, in the spring of 1576, with two small vessels of 20 to 25 tons, called the "Gabriel" and "Michael." But the "Michael" parted company in the Atlantic, the voyage being continued in the "Gabriel" alone. On 20th July Frobisher sighted high land, which he called Queen Elizabeth's Foreland; and the next day he entered the strait to which he gave his own name, calling the land "Meta Incognita." On his return in the autumn, with various specimens of plants and stones, the "goldfinders" in London took it into their heads that a glittering piece of mica-schist contained gold ore. This caused great excitement, and much larger expeditions were fitted out, in the two following years, to collect these precious ores. As many as fifteen vessels formed the third expedition of 1578, and one of them, a busse (small ship) of Bridgwater, called the "Emma," reported that on her voyage home she had sighted land in the Atlantic and sailed along it for three days. It was never seen again, and may have been only a large ice-field; but it soon found its place on maps and charts under the name of Busse Island, and afterwards as "sunken land of Busse." For a long time Frobisher Strait was supposed to pass through Greenland, and the map of the Zeni adding to the confusion, the land to the south was called Frislanda. It is now clear that Frobisher never saw Greenland, and that his strait and "Meta Incognita" are on the American side of Davis Strait. What Frobisher

<sup>1</sup> Admiral Irminger of Copenhagen holds the opinion that Frisland is not the Faroe Isles, but Iceland.

really did was to establish the fact that there were two or more wide openings leading to the westward, between latitudes 60° and 63°, on the American coast.

**Davis.** John Davis, who made the next attempt to discover a north-west passage, was one of the most scientific seamen of that age. He made three voyages in three successive years, aided and fitted out by William Sanderson and other merchants. Sailing from Dartmouth on the 7th June 1585, he was the first to visit the west coast of Greenland subsequent to the abandonment of the Norse colonies. He called it "The Land of Desolation." He discovered Gilbert's Sound in 64° 10' (where now stands the Danish settlement of Godthaab) and then, crossing the strait which bears his name, he traced a portion of its western shore. In the second voyage Davis noted what he calls "a furious overfall," which was the tide flowing into Hudson Strait; and in his third voyage, in 1587, he advanced far up his own strait, and reached a lofty granite island in 72° 41' N. which he named Sanderson's Hope. He considered that there was good hope of advancing farther, and reported "no ice towards the north, but a great sea, free, large, very salt and blue, and of an unsearchable depth." The results of his discoveries are shown on the Molyneux globe which is now in the library of the Middle Temple; but he found it impossible to reconcile his work with that of Frobisher, and with the Zeni map. In 1595 Davis published a tract entitled *The World's Hydrographical Description*, in which he ably states the arguments in favour of the discovery of a north-west passage.

The Dutch also saw the importance of a northern route to China and India, especially as the routes by the Cape of Good Hope and Magellan's Strait were jealously guarded by Spaniards and Portuguese. Their plan was to proceed by the north-east along the coast of Asia. As early as 1578 Dutch merchants had opened a trade with Kola and Archangel, but it was Peter Plancius, the learned cosmographer of Amsterdam, who conceived the idea of discovering a north-east passage. In 1594 the Amsterdam merchants fitted out a vessel of 100 tons, under the command of Willem Barents. The coast of Nova Zembla was sighted on the 4th July, and from that date until the 3rd of August Barents continued perseveringly to seek a way through the ice-floes, and discovered the whole western coast as far as Cape Nassau and the Orange Islands at the north-west extremity. The second voyage in which Barents was engaged merely made an unsuccessful attempt to enter the Kara Sea. The third was more important. Two vessels sailed from Amsterdam on May 13, 1596, under the command of Jacob van Heemskerck and Corneliszoon Rijp. Barents accompanied Heemskerck as pilot, and Gerrit de Veer, the historian of the voyage, was on board as mate. The masses of ice in the straits leading to the Sea of Kara, and the impenetrable nature of the pack near Nova Zembla, had suggested the advisability of avoiding the land and, by keeping a northerly course, of seeking a passage in the open sea. They sailed northwards and on 9th June discovered Bear Island. Continuing on the same course they sighted the north-western extreme of Spitzbergen, soon afterwards being stopped by the polar pack ice. This important discovery was named "Nieuwe Land," and was believed to be a part of Greenland. Arriving at Bear Island again on 1st July, Rijp parted company, while Heemskerck and Barents proceeded eastward, intending to pass round the northern extreme of Nova Zembla. On the 26th August they reached Ice Haven, after rounding the northern extremity of the land. Here they wintered in a house built out of driftwood and planks from the wrecked vessel. In the spring they made their way in boats to the Lapland coast; but Barents died during the

voyage. This was the first time that an arctic winter was successfully faced. The voyages of Barents stand in the first rank among the polar enterprises of the 16th century. They led directly to the flourishing whale and seal fisheries which long enriched the Netherlands.

The English enterprises were continued by the Muscovy Company, and by associations of patriotic merchants of London; and even the East India Company sent an expedition under Captain Waymouth in 1602 to seek for a Way-passage by the opening seen by Davis, but it had no success, mouth.

The best servant of the Muscovy Company in the work of polar discovery was Henry Hudson. His first voyage Hudson was undertaken in 1607, when he discovered the most northern known point of the east coast of Greenland in 73° N. named "Hold with Hope," and examined the edge of the ice between Greenland and Spitzbergen, reaching a latitude of 80° 23' N. On his way home he discovered the island now called Jan Mayen, which he named "Hudson's Tutches." In his second expedition, during the season of 1608, Hudson examined the edge of the ice between Spitzbergen and Nova Zembla. In his third voyage he was employed by the Dutch East India Company, and he explored the coasts of North America, discovering the Hudson river. In 1610 he discovered Hudson's Strait, and the great bay which bears and immortalizes his name (see HUDSON, vol. xii. p. 332).

The voyages of Hudson led immediately to the Spitz-Spitz-bergen whale fishery. From 1609 to 1612 Jonas Poole <sup>Spitz-bergen whale fishery.</sup> made four voyages for the prosecution of this lucrative business, and he was followed by Fotherby, Baffin, Joseph, and Edge. These bold seamen, while in the pursuit of whales, added considerably to the knowledge of the archipelago of islands known under the name of Spitzbergen, and in 1617 Captain Edge discovered a large island to the eastward, which he named Wyche's Land.

At about the same period the kings of Denmark began Danish to send expeditions for the rediscovery of the lost Green- <sup>voyages.</sup> land colony. In 1605 Christian IV. sent out three ships, under the Englishmen Cunningham and Hall, and a Dane named Lindenov, which reached the western coast of Greenland and had much intercourse with the Eskimo. Other expeditions followed in 1606-7.

Meanwhile the merchant adventurers of London con- <sup>Button.</sup> tinued to push forward the western discovery. Sir Thomas Button, in command of two ships, the "Resolution" and "Discovery," sailed from England in May 1612. He entered Hudson's Bay, crossed to its western shore, and wintered at the mouth of a river in 57° 10' N. which was named Nelson's river after the master of the ship, who died and was buried there. Next year Button explored the shore of Southampton Island as far as 65° N., and returned home in the autumn of 1613. An expedition under Captain Gibbons, despatched in 1614, was a miserable failure; but in 1615 Robert Bylot as master and William Baffin as pilot and navigator in the "Discovery" examined the coasts of Hudson's Strait, and Baffin, who Baffin. was the equal of Davis as a scientific seaman, made many valuable observations. In 1616 Bylot and Baffin again set out in the "Discovery." Sailing up Davis Strait they passed that navigator's farthest point at Sanderson's Hope, and sailed round the great channel with smaller channels leading from it which has been known ever since as Baffin's Bay. Baffin named the most northern opening Smith Sound, after the first governor of the East India Company, and the munificent promoter of the voyage, Sir Thomas Smith. Wolstenholme Sound, Cape Dudley Digges, Hakluyt Island, Lancaster Sound, Jones Sound, and the Cary Islands were named after other promoters and friends of the voyage. The fame of Baffin mainly rests upon the discovery of the great channel extending

north from Davis Strait; but it was unjustly dimmed for many years, owing to the omission of Purchas to publish the skilful navigator's tabulated journal and map in his great collection of voyages. It may be mentioned, as an illustration of the value of these early voyages to modern science, that Professor Hansteen of Christiania made use of Baffin's magnetic observations in the compilation of his series of magnetic maps.

In 1631 two expeditions were despatched, one by the merchants of London, the others by those of Bristol. In the London ship "Charles" Luke Fox explored the western side of Hudson's Bay as far as the place called "Sir Thomas Roe's Welcome." In August he encountered Captain James and the Bristol ship "Maria" in the middle of Hudson's Bay, and went north until he reached "North-west Fox his furthest," in 66° 47' N. He then returned home and wrote the most entertaining of all the polar narratives. Captain James was obliged to winter off Charlton Island, in the southern extreme of Baffin's Bay, and did not return until October 1632. Another English voyager, Captain Wood, attempted, without success, to discover a north-east passage in 1676.

The 16th and 17th centuries were periods of discovery and daring enterprise, and the results gained by the gallant seamen of those times are marvellous when we consider their insignificant resources and the small size of their vessels. Hudson's Strait and Bay, Davis Strait, and Baffin's Bay, the icy seas from Greenland to Spitzbergen and from Spitzbergen to Nova Zembla, had all been discovered. The following century was rather a period of reaping the results of former efforts than of discovery. It saw the settlement of the Hudson's Bay Territory and of Greenland, and the development of the whale and seal fisheries.

The Hudson's Bay Company was incorporated in 1670, and Prince Rupert sent out Zachariah Gillan, who wintered at Rupert's river. At first very slow progress was made. A voyage undertaken by Mr Knight, who had been appointed governor of the factory at Nelson river, was unfortunate, as his two ships were lost and the crews perished. This was in 1719. In 1722 John Scroggs was sent from Churchill river in search of the missing ships, but merely entered Sir Thomas Roe's Welcome and returned. His reports were believed to offer decisive proofs of the existence of a passage into the Pacific; and a naval expedition was despatched under the command of Captain Christopher Middleton, consisting of the "Discovery" pink and the "Furnace" bomb. Wintering in Churchill river, Middleton started in July 1742 and discovered Wager river and Repulse Bay. In 1746 Captain W. Moor made another voyage in the same direction, and explored the Wager Inlet. Captain Coats, who was in the service of the company 1727-51, wrote a useful account of the geography of Hudson's Bay. Later in the century the Hudson's Bay Company's servants made some important land journeys to discover the shores of the American polar ocean. From 1769 to 1772 Samuel Hearne descended the Coppermine river to the polar sea; and in 1789 Alexander Mackenzie discovered the mouth of the Mackenzie river.

The establishment of the modern Danish settlements in Greenland has already been spoken of under the heading GREENLAND (*q.v.*).

The countrymen of Barents vied with the countrymen of Hudson in the perilous calling which annually brought fleets of ships to the Spitzbergen seas during the 18th century. The Dutch had their large summer station for boiling down blubber at Smeerenberg, near the northern extreme of the west coast of Spitzbergen. Captain Vlamingh, in 1664, advanced as far round the northern

end of Nova Zembla as the winter quarters of Barents. In 1700 Captain Cornelis Roule is said by Witsen to have sailed north in the longitude of Nova Zembla, and to have seen an extent of 40 miles of broken land. But Theunis Ys, one of the most experienced Dutch navigators, was of opinion that no vessel had ever been north of the 82d parallel. In 1671 Frederick Martens visited the Spitzbergen group, and wrote the best account of its physical features and natural history that existed previous to the time of Scoresby. In 1707 Captains Gilies and Outsager Rep went far to the eastward along the northern shores of Greenland, and saw very high land in 80° N, which has since been known as Gilies Land. The Dutch geographical knowledge of Spitzbergen was embodied in the famous chart of the Van Keulens (father and son), 1700-1728. The Dutch whale fishery continued to flourish until the French Revolution, and formed a splendid nursery for training the seamen of the Netherlands. From 1700 to 1775 the fleet numbered 100 ships and upwards. In 1719 the Dutch opened a whale fishery in Davis Strait, and continued to frequent the west coast of Greenland for upwards of sixty years from that time. In the course of 6372 Dutch whaling voyages to Davis Strait between 1719 and 1775 only 38 ships were wrecked.

The most flourishing period of the English fishery in the Spitzbergen seas was from 1752 to 1820. Bounties of 40s. per ton were granted by Act of Parliament; and in 1778 as many as 255 sail of whalers were employed. In order to encourage discovery £5000 were offered in 1776 to the first ship that should sail beyond the 89th parallel (16 Geo. III. c. 6). Among the numerous daring and able whaling captains, Captain Scoresby takes the first rank, alike as a successful fisher and a scientific observer. His admirable *Account of the Arctic Regions* is still a text book for all students of the subject. In 1806 he succeeded in advancing his ship "Resolution" as far north as 81° 12' 42". In 1822 he forced his way through the ice which ennumbers the approach to land on the east coast of Greenland, and surveyed that coast from 75° down to 69° N., a distance of 400 miles. Scoresby combined the closest attention to his business with much valuable scientific work and no insignificant amount of exploration.

The Russians, after the acquisition of Siberia, succeeded in gradually exploring the whole of the northern shores of that vast region. As long ago as 1648 a Cossack named Simon Desnneff equipped a boat expedition in the river Kolyma, passed through the strait afterwards named after Bering, and reached the Gulf of Anadyr. In 1738 a voyage was made by two Russian officers from Archangel to the mouths of the Obi and the Yenisei. Efforts were then made to effect a passage from the Yenisei to the Lena. In 1735 Lieutenant T. Tchelyuskin got as far as Tchelyuskin. 77° 25' N. near the cape which bears his name; and in 1743 he reached that most northern point of Siberia in sledges, in 77° 41' N. Captain Vitus Bering, a Dane, was appointed by Peter the Great to command an expedition in 1725. Two vessels were built at Okhotsk, and in July 1728 Bering ascertained the existence of a strait between Asia and America. In 1740 Bering was again employed. He sailed from Okhotsk in a vessel called the "St Paul," with G. W. Steller on board as naturalist. Their object was to discover the American side of the strait, and they sighted that magnificent peak named by Bering Mount St Elias. The Aleutian Islands were also explored, but the ship was wrecked on an island named after the ill-fated discoverer, and scurvy broke out amongst his crew. Bering himself died there on December 8, 1741.

Thirty years after the death of Bering a Russian merchant named Liakhoff discovered the New Siberia or Liakhoff Islands, and in 1771 he obtained the exclusive

These islands were more fully explored by an officer named Hedenström in 1809, and seekers for fossil ivory annually resorted to them. A Russian expedition under Captain Tchitschakoff, sent to Spitzbergen in 1764, was only able to attain a latitude of 80° 30' N.

Phipps. Since the year 1773 the objects of polar exploration, at least so far as England is concerned, have been mainly the acquisition of knowledge in various branches of science. It was on these grounds that the Honourable Daines Barrington and the Royal Society induced the Government to undertake arctic exploration once more. The result was that two vessels, the "Racehorse" and "Carcass" bombs, were commissioned, under the command of Captain Phipps. The expedition sailed from the Nore on the 2d June 1773, and was stopped by the ice to the north of Hakluyt Headland, the north-western point of Spitzbergen. They reached the Seven Islands and discovered Walden Island; but beyond this point progress was impossible. When they attained their highest latitude in 80° 48' N., north of the central part of the Spitzbergen group, the ice at the edge of the pack was 24 feet thick. Captain Phipps returned to England in September 1773. Five years afterwards Captain Cook received instructions to proceed northward from Kamchatka and search for a north-east or north-west passage from the Pacific to the Atlantic. In accordance with these orders Captain Cook, during his third voyage, reached Cape Prince of Wales, the western extremity of America, on August 9, 1778. His ships, the "Resolution" and "Discovery," arrived at the edge of the ice, after passing Behring Strait, in 70° 41' N. On August 17th the farthest point seen on the American side was named Icy Cape. On the Asiatic side Cook's survey extended to Cape North. In the following year Captain Clerke, who had succeeded to the command, made another attempt, but his ship was beset in the ice, and so much damaged that further attempts were abandoned.

Barrow. The wars following the French Revolution put an end to voyages of discovery till, after the peace of 1815, north polar research found a powerful and indefatigable advocate in Sir John BARROW (q.v.). Through his influence a measure for promoting polar discovery became law in 1818 (58 Geo. III. c. 20), by which a reward of £20,000 was offered for making the north-west passage, and of £5000 for reaching 89° N., while the commissioners of longitude were empowered to award proportionate sums to those who might achieve certain portions of such discoveries. In 1817 the icy seas were reported by Captain Scoresby and others to be remarkably open, and this circumstance enabled Barrow to obtain sanction for the despatch of two expeditions, each consisting of two whalers—one to attempt discoveries by way of Spitzbergen and the other by Baffin's Bay. The vessels for the Spitzbergen route, the "Dorothea" and "Trent," were commanded by Captain David Buchan and Lieutenant John Franklin, and sailed in April 1818. Driven into the pack by a heavy swell from the south, both vessels were severely nipped, and had to return to England. The other expedition, consisting of the "Isabella" and "Alexander," commanded by Captain John Ross and Lieutenant Edward Parry, followed in the wake of Baffin's voyage of 1616. Ross sailed from England in April 1818. The chief merit of his voyage was that it vindicated Baffin's accuracy as a discoverer. Its practical result was that the way was shown to a very lucrative fishery in the "North Water" of Baffin's Bay, which continued to be frequented by a fleet of whalers every year. Captain Ross thought that the inlets reported by Baffin were merely bays, while the opinion of his second in command was that a wide opening to the westward existed through Lancaster Sound of Baffin.

Parry was consequently selected to command a new expedition in the following year. His two vessels, the "Hecla" and "Griper," passed through Lancaster Sound, the continuation of which he named Barrow Strait, and advanced westward, with an archipelago on his starboard hand, since known as the Parry Islands. He observed a wide opening to the north, which he named Wellington Channel, and sailed onwards for 300 miles to Melville Island. He was stopped by that impenetrable polar pack of vast thickness which appears to surround the archipelago to the north of the American continent, and was obliged to winter in a harbour on the south coast of Melville Island. Parry's sanitary arrangements during the winter were very judicious, and the scientific results of his expedition were most valuable. The vessels returned in October 1820; and a fresh expedition in the "Fury" and "Hecla," again under the command of Captain Parry, sailed from the Nore on May 8, 1821, and passed their first winter on the coast of the newly discovered Melville Peninsula in 66° 11' N. Still persevering, Parry passed his second winter among the Eskimo at Igloolik in 69° 20' N., and discovered a channel leading westward from the head of Hudson's Bay, which he named Fury and Hecla Strait. The expedition returned in the autumn of 1823. Meantime Parry's friend Franklin had been employed in attempts to reach by land the northern shores of America, hitherto only touched at two points by Hearne and Mackenzie. Franklin went out in 1819, accompanied by Dr Richardson, George Back, and Hood. They landed at York factory, and proceeded to the Great Slave Lake. In August of the following year they started for the Coppermine river, and, embarking on it, reached its mouth on July 18, 1821. From that point 550 miles of coast-line were explored, the extreme point being called Cape Turnagain. Most frightful sufferings, from starvation and cold, had to be endured during the return journey; but eventually Franklin, Richardson, and Back arrived safely at Fort Chippewyan. It was now thought desirable that an attempt should be made to connect the Cape Turnagain of Franklin with the discoveries made by Parry during his second voyage; but the first effort, under Captain Lyon in the "Griper," was unsuccessful.

In 1824 three combined attempts were organized. Parry's While Parry again entered by Lancaster Sound and pushed third down a great opening he had seen to the south named voyage. Prince Regent's Inlet, Captain Beechey was to enter Behring's Strait, and Franklin was to make a second journey to the shores of Arctic America. Parry was unfortunate, but Beechey entered Behring Strait in the "Blossom" in Beechey. August 1826, and extended our knowledge as far as Point Barrow in 71° 23' 30" H. lat. Franklin, in 1825-26, Frank- descended the Mackenzie river to its mouth, and ex- lin's plored the coast for 374 miles to the westward; while second journey. Dr Richardson discovered the shore between the mouths of the Mackenzie and Coppermine, and sighted land to the northward, named by him Wollaston Land, the dividing channel being called Union and Dolphin Strait. They returned in the autumn of 1826.

Work was also being done in the Spitzbergen and Barents Seas. From 1821 to 1824 the Russian Captain Lutke. Lutke was surveying the west coast of Nova Zembla as far as Cape Nassau, and examining the ice of the adjacent sea. In May 1823 the "Griper" sailed, under the command of Captain Clavering, to convey Captain Sabine to Clavering the polar regions in order to make pendulum observations. ing. Clavering pushed through the ice in 75° 30' N., and succeeded in reaching the east coast of Greenland, where observations were taken on Pendulum Island. He laid down the land from 76° to 72° N.

Parry's attempt in 1827 to reach the pole from the

Parry's attempt to reach the pole. northern coast of Spitzbergen, by means of sledge-boats, has been described under the heading PARRY. The highest latitude reached was  $82^{\circ} 45' N.$ ; and the attempt showed that it is useless to leave the land and trust to the drifting pack in polar exploration.

In 1829 the Danes undertook an interesting piece of exploration on the east coast of Greenland. Captain Graah. Graah of the Danish navy rounded Cape Farewell in boats, with four Europeans and twelve Eskimo. He advanced as far as  $65^{\circ} 18' N.$  on the east coast, where he was stopped by an insurmountable barrier of ice. He wintered at Nugarlik in  $63^{\circ} 22' N.$ , and returned to the settlements on the west side of Greenland in 1830.

The Rosses. In the year 1829 Captain John Ross, with his nephew James, having been furnished with sufficient funds by a wealthy distiller named Felix Booth, undertook a private expedition of discovery in a small vessel called the "Victory." Ross proceeded down Prince Regent's Inlet to the Gulf of Boothia, and wintered on the eastern side of a land named by him Boothia Felix. In the course of exploring excursions during the summer months James Ross crossed the land and discovered the position of the north magnetic pole on the western side of it, on June 1, 1831. He also discovered a land to the westward of Boothia which he named King William Land, and the northern shore of which he examined. The most northern point, opposite the magnetic pole, was called Cape Felix, and thence the coast trended south-west to Victory Point. James Ross was at Cape Felix on May 29, 1830. The Rosses never could get their little vessel out of its winter quarters. They passed three winters there, and then fell back on the stores at Fury Beach, where they passed their fourth winter of 1832-33. Eventually they were picked up by a whaler in Barrow Strait, and brought home. Great anxiety was naturally felt at their prolonged absence, and in 1833 Sir George Back, with Dr Richard King as a companion, set out by land in search of the missing explorers. Wintering at the Great Slave Lake, he left Fort Reliance on June 7, 1834, and descended the Great Fish River, which is obstructed by many falls in the course of a rapid and tortuous course of 530 miles. The mouth was reached in  $67^{\circ} 11' N.$ , when the want of supplies obliged them to return. In 1836 Sir George Back was sent, at the suggestion of the Royal Geographical Society, to proceed to Repulse Bay in his ship, the "Terror," and then to cross an assumed isthmus and examine the coast-line thence to the mouth of the Great Fish River; but the ship was obliged to winter in the drifting pack, and was brought back across the Atlantic in a sinking condition.

Simpson and Dease. The tracing of the polar shores of America was completed by the Hudson's Bay Company's servants. In June 1837 Messrs Simpson and Dease left Chippewyan, reached the mouth of the Mackenzie, and connected that position with Point Barrow, which had been discovered by the "Blossom" in 1826. In 1839 Simpson passed Cape Turnagain of Franklin, tracing the coast eastward so as to connect with Back's work at the mouth of the Great Fish River. He landed at Montreal Island in the mouth of that river, and then advanced eastward as far as Castor and Pollux river, his farthest eastern point. On his return he travelled along the north side of the channel, which is in fact the south shore of the King William Island discovered by James Ross. The south-western point of this island was named Cape Herschel, and there Simpson built a cairn on August 26, 1839. Very little more remained to be done in order to complete the delineation of the northern shores of the American continent. This was entrusted to Dr John Rae, a Hudson's Bay factor, in 1846. He went in boats to Repulse Bay, where he wintered in a stone hut

nearly on the Arctic Circle; and he and his six Orkney men maintained themselves on the deer they shot. During the spring of 1847 Dr Rae explored on foot the shores of a great gulf having 700 miles of coast-line. He thus connected the work of Parry, at the mouth of Fury and Hecla Strait, with the work of Ross on the coast of Boothia, proving that Boothia was part of the American continent.

While the English were thus working hard to solve some of the geographical problems relating to Arctic America, the Russians were similarly engaged in Siberia. In 1821 Lieutenant Anjou made a complete survey of the Anjou. New Siberia Islands, and came to the conclusion that it was not possible to advance far from them in a northerly direction, owing to the thinness of the ice and to open water within 20 or 30 miles. Baron Wrangell prosecuted Wrangell similar investigations from the mouth of the Kolyma between 1820 and 1823. He made four journeys with dog sledges, exploring the coast between Cape Tchelagaskoi and the Kolyma, and making attempts to extend his journeys to some distance from the land. He was always stopped by thin ice, and he received tidings from a native chief of the existence of land at a distance of several leagues to the northward. In 1843 Middendorf was sent Middendorf to explore the region which terminates in Cape Tcheluskin. He reached the cape in the height of the short summer, whence he saw open water and no ice blink in any direction. The whole arctic shore of Siberia had now been explored and delineated, but no vessel had yet rounded the extreme northern point, by sailing from the mouth of the Yenisei to that of the Lena. When that feat was achieved the problem of the north-east passage would be solved.

The success of Sir James Ross's Antarctic expedition Franklin and the completion of the northern coast-line of America expedition. by the Hudson's Bay Company's servants gave rise in 1845 to a fresh attempt to make the passage from Lancaster Sound to Behring Strait. The story of this unhappy expedition of Sir John Franklin, in the "Erebus" and "Terror," has already been told under FRANKLIN (q.v.); but some geographical details may be given here.

To understand clearly the nature of the obstacle which finally stopped Sir John Franklin, and which also stopped Sir Edward Parry in his first voyage, it is necessary to refer to the map. Westward of Melville and Baring Islands, northward of the western part of the American coast, and northward of the channel leading from Smith Sound, there is a vast unknown space, the ice which ennumbers it never having been traversed by any ship. All navigators who have skirted along its edge describe the stupendous thickness and massive proportions of the vast floes with which it is packed. This accumulation of ice of enormous thickness, to which Sir George Nares has given the name of a "Palæocrystic Sea," arises from the absence of direct communication between this portion of the north polar region and the warm waters of the Atlantic and Pacific. Behring Strait is the only vent in a south-westerly direction, and that channel is so shallow that the heavy ice grounds outside it. In other directions the channels leading to Baffin's Bay are narrow and tortuous. In one place only is there a wide and straight lead. The heavy polar ice flows south-east between Melville and Baring Islands, down what is now called McClintock Channel, and impinges on the north-west coast of the King William Land discovered by James Ross. It was this branch of the palæocrystic sea which finally stopped the progress of Franklin's expedition. On leaving the winter-quarters at Beechey Island in 1846, Franklin found a channel leading south, along the western shore of the land of North Somerset discovered by Parry in 1819. If he could reach the channel on the American coast, he knew that he would be able

to make his way along it to Behring Strait. This channel leading south, now called Peel Sound, pointed directly to the south. He sailed down it towards King William Island, with land on both sides. But directly they passed the southern point of the western land, and were no longer shielded by it, the great palæocrystic stream from Melville Island was fallen in with, pressing on King William Island. It was impassable. The only possibility of progress would have been by rounding the eastern side of King William Island, but its insularity was then unknown.

Search  
expedi-  
tions.  
Ross.

It was not until 1848 that anxiety began to be felt about the Franklin expedition. In the spring of that year Sir James Ross was sent with two ships, the "Enterprise" and "Investigator," by way of Lancaster Sound. He wintered at Leopold Harbour, near the north-east point of North Devon. In the spring he made a long sledge journey with Lieutenant M'Clintock along the northern and western coasts of North Somerset.

Austin.

On the return of the Ross expedition without any tidings, the country became thoroughly alarmed. An extensive plan of search was organized,—the "Enterprise" and "Investigator" under Collinson and M'Clure proceeding by Behring Strait, while the "Assistance" and "Resolute" with two steam tenders, the "Pioneer" and "Intrepid," sailed May 3, 1850, to renew the search by Barrow Strait, under Captain Austin. Two brigs, the "Lady Franklin" and "Sophia," under Captain Penny, a very energetic and able whaling captain, were sent by the same route. He had with him Dr Sutherland, a naturalist, who did much valuable scientific work. Austin and Penny entered Barrow Strait, and Franklin's winter-quarters of 1845-46 were discovered at Beechey Island; but there was no record of any kind indicating the direction taken by the ships. Stopped by the ice, Austin's expedition wintered (1850-51) in the pack off Griffith Island, and Penny found refuge in a harbour on the south coast of Cornwallis Island. Austin, who had been with Parry during his third voyage, was an admirable organizer. His arrangements for passing the winter were carefully thought out and answered perfectly. In concert with Penny he planned a thorough and extensive system of search by means of sledge travelling in the spring; and Lieutenant M'Clintock superintended every minute detail of this part of the work with unfailing forethought and consummate skill. Penny undertook the search by Wellington Channel. M'Clintock advanced to Melville Island, marching over 770 miles in eighty-one days; Captain Ommanney and Sherard Osborn pressed southward and discovered Prince of Wales Island. Lieutenant Brown examined the western shore of Peel Sound. The search was exhaustive; but, except the winter-quarters at Beechey Island, no record, no sign was discovered. The absence of any record made Captain Austin doubt whether Franklin had ever gone beyond Beechey Island. So he also examined the entrance of Jones Sound, the next inlet from Baffin's Bay north of Lancaster Sound, on his way home, and returned to England in the autumn of 1851. This was a thoroughly well-conducted expedition,—especially as regards the sledge travelling, which M'Clintock brought to great perfection. So far as the search for Franklin was concerned, nothing remained to be done west or north of Barrow Strait.

Kennedy.

Bellet.

In 1851 the "Prince Albert" schooner was sent out by Lady Franklin, under Captain Kennedy, with Lieutenant Bellot of the French navy as second. They wintered on the east coast of North Somerset, and in the spring of 1852 the gallant Frenchman, in the course of a long sledging journey, discovered Bellot Strait separating North Somerset from Boothia,—this proving that the Boothia coast facing the strait was the northern extremity of the continent of America.

The "Enterprise" and "Investigator" sailed from Collinson. England in January 1850, but accidentally parted company before they reached Behring Strait. On May 6, 1851, the "Enterprise" passed the strait, and rounded Point Barrow on the 25th. Collinson then made his way up the narrow Prince of Wales Strait, between Baring and Prince Albert Island, and reached Princess Royal Islands, where M'Clure had been the previous year. Returning southwards, the "Enterprise" wintered in a sound in Prince Albert Island in  $71^{\circ} 35' N$  and  $117^{\circ} 35' W$ . Three travelling parties were despatched in the spring of 1852,—one to trace Prince Albert Land in a southerly direction, while the others explored Prince of Wales Strait, one of them reaching Melville Island. In September 1852 the ship was free, and Collinson pressed eastward along the coast of North America, reaching Cambridge Bay (September 26), where the second winter was passed. In the spring he examined the shores of Victoria Land as far as  $70^{\circ} 26' N$ . and  $100^{\circ} 45' W$ . He was within a few miles of Point Victory, where the fate of Franklin would have been ascertained. The "Enterprise" again put to sea on August 5, 1853, and returned westward along the American coast, until she was stopped by ice and obliged to pass a third winter at Camden Bay, in  $70^{\circ} 8' N$ . and  $145^{\circ} 29' W$ . In 1854 this most remarkable voyage was completed, and Captain Collinson brought the "Enterprise" back to England.

Meanwhile M'Clure in the "Investigator" had passed M'Clure. the winter of 1850-51 at the Princess Royal Islands, only 30 miles from Barrow Strait. In October M'Clure ascended a hill whence he could see the frozen surface of Barrow Strait which was navigated by Parry in 1819-20. Thus, like the survivors of Franklin's crews when they reached Cape Herschel, M'Clure discovered a north-west passage. It was impossible to reach it, for the branch of the palæocrystic ice which stopped Franklin off King William Land was athwart their northward course. So, as soon as he was free in 1851, M'Clure turned southwards, round the southern extreme of Baring Island, and commenced to force a passage to the northward between the western shore of that land and the enormous fields of ice which pressed upon it. The cliffs rose up like walls on one side, while on the other the stupendous ice of the palæocrystic sea rose from the water to a level with the "Investigator's" lower yards. After many hair-breadth escapes M'Clure took refuge in a bay on the northern shore of Bank's Land, which he named "The Bay of God's Mercy." Here the "Investigator" remained, never to move again. After the winter of 1851-52 M'Clure made a journey across the ice to Melville Island, and left a record at Parry's winter harbour. Abundant supplies of musk ox were fortunately obtained, but a third winter had to be faced. In the spring of 1853 M'Clure was preparing to abandon the ship with all hands, and attempt, like Franklin's crews, to reach the American coast. But succour providentially arrived in time.

The Hudson's Bay Company assisted in the search for Rae's Franklin. In 1848 Sir John Richardson and Dr Rae journeyed. examined the American coast from the mouth of the Mackenzie to that of the Coppermine. In 1849 and 1850 Rae continued the search; and by a long sledge journey in the spring of 1851, and a boat voyage in the summer, he examined the shores of Wollaston and Victoria Lands, which were afterwards explored by Captain Collinson in the "Enterprise."

In 1852 the British Government resolved to despatch another expedition by Lancaster Sound. Austin's four vessels were recommissioned, and the "North Star" was sent out as a depot ship at Beechey Island. Sir Edward Belcher commanded the "Assistance," with the "Pioneer" Belcher. under Sherard Osborn as steam tender. He went up Well-

ton Channel to Northumberland Bay, where he wintered, passing a second winter lower down in Wellington Channel, and then abandoning his ships and coming home in 1854. But Sherard Osborn and Commander Richards did good work. They made sledge journeys to Melville Island, and thus discovered the northern side of the Parry group. Captain Kellett received command of the "Resolute," with M'Clintock in the steam tender "Intrepid." Among Kellett's officers were the best of Austin's sledge travellers, M'Clintock, Meham, and Vesey Hamilton, so that good work was sure to be done. George Nares, the future leader of the expedition of 1874-75, was also on board the "Resolute." Kellett passed onwards to the westward and passed the winter of 1852-53 at Melville Island. During the autumn Meham discovered M'Clure's record, and the position of the "Investigator" was thus ascertained. The safety of her crew was consequently assured, for it was only necessary to send a message across the strait between two fixed positions. This service was performed by Lieutenant Pim early in the following spring. The officers and crew of the "Investigator," led by M'Clure, arrived safely on board the "Resolute" on June 17, 1853, and they reached England in the following year. They not only discovered but traversed a north-west passage, though not in the same ship, and partly by travelling over ice. For this great feat M'Clure received the honour of knighthood,—a reward of £10,000 being granted to himself, the other officers, and the crew, by a vote of the House of Commons.

Kellett.

Sledge travelling.

The travelling parties of Kellett's expedition, led by M'Clintock, Meham, and Vesey Hamilton, completed the discovery of the northern and western sides of Melville Island, and the whole outline of the large Island of Prince Patrick, still further to the westward. M'Clintock was away from the ship with his sledge party for one hundred and five days and travelled over 1328 miles. Meham was away ninety-four days and travelled over 1163 miles. Sherard Osborn, in 1853, was away ninety-seven days and travelled over 935 miles. The "Resolute" was obliged to winter in the pack in 1853-54, and in the spring of 1854 Meham made a most remarkable journey in the hope of obtaining news of Captain Collinson at the Princess Royal Islands. Leaving the ship on 3d April he was absent seventy days, out of which there were sixty-one and a half days of travelling. The distance gone over was 1336 statute miles. The average rate of the homeward journey was  $23\frac{1}{2}$  miles a day, the average time of travelling each day nine hours twenty-five minutes. This journey is without a parallel in arctic records.

Fearing detention for another winter, Sir Edward Belcher ordered all the ships to be abandoned in the ice, the officers and crews being taken home in the "North Star," and in the "Phoenix" and "Talbot" which had come out from England to communicate. They reached home in October 1854. In 1852 Captain Inglefield, R.N., had made a voyage up Baffin's Bay in the "Isabel" as far as the entrance of Smith Sound. In 1853 and 1854 he came out in the "Phoenix" to communicate with the "North Star" at Beechey Island. The drift of the "Resolute" was a remarkable proof of the direction of the current out of Barrow Strait. She was abandoned in  $74^{\circ} 41' N.$  and  $101^{\circ} 11' W.$  on May 14, 1854. On September 10, 1855, an American whaler sighted the "Resolute" in  $67^{\circ} N.$  lat. about twenty miles from Cape Mercy, in Davis Strait. She was brought into an American port, and eventually presented to the British Government. She had drifted nearly a thousand miles.

Inglefield.

Drift of the "Resolute."

In 1853 Dr Rae was employed to connect a few points which would quite complete the examination of the coast of America, and establish the insularity of King William

Land. He went up Chesterfield Inlet and the river Relics Quioch for a considerable distance, wintering with eight men at Repulse Bay in a snow house. Venison and fish were abundant. In 1854 he set out on a journey which occupied fifty-six days in April and May. He succeeded in connecting the discoveries of Simpson with those of James Ross, and thus established the fact that King William Land was an island. Rae also brought home tidings and relics of Franklin's expedition gathered from the Eskimo; and this led to the expedition of M'Clintock in the "Fox," already described in the article FRANKLIN (vol. ix. p. 721-22). While M'Clintock was prosecuting his exhaustive search over part of the west coast of Boothia, the whole of the shores of King William Island, the mouth of the Great Fish River, and Montreal Island, Allen Young completed the discovery of the southern side of Prince of Wales Island. The "Fox" returned to England in the autumn of 1859.

The catastrophe of Sir John Franklin's expedition led to 7000 miles of coast-line being discovered, and to a vast extent of unknown country being explored, securing very considerable additions to geographical knowledge. Much attention was also given to the collection of information, and the scientific results of the various search expeditions were considerable. The catastrophe also afforded a warning which would render any similar disaster quite inexcusable. If arrangements are always carefully made for a retreat beforehand, if a depôt ship is always left within reach of the advancing expedition as well as of the outer world, and if there is annual communication, with positive rules for depositing records, no such catastrophe can ever happen again.

Work of the search expeditions.

The American nation was first led to take an interest in polar research through a very noble and generous feeling of sympathy for Franklin and his brave companions. Mr Grinnell of New York gave practical expression to this feeling. In 1850 he equipped two vessels, the "Advance" and "Rescue," to aid in the search, commanded by Lieutenants De Haven and Griffith, and accompanied by Dr Kane. They reached Beechey Island on August 27, 1850, and assisted in the examination of Franklin's winter-quarters, but returned without wintering. In 1853 Dr Kane, in the little brig "Advance" of 120 tons, undertook to lead an American expedition up Smith Sound, the most northern outlet from Baffin's Bay. The "Advance" reached Smith Sound on the 7th August 1853, but was stopped by ice in  $78^{\circ} 45' N.$  only 17 miles from the entrance. He described the coast as consisting of precipitous cliffs 800 to 1200 feet high, and at their base there was a belt of ice about 18 feet thick, resting on the beach. Dr Kane adopted the Danish name of "ice-foot" (*is fod*) for this permanent frozen ridge. He named the place of his winter-quarters Van Rensselaer Harbour. In the spring some interesting work was done. A great glacier was discovered and named the Humboldt glacier, with a sea face 45 miles long. Dr Kane's steward, Morton, crossed the foot of this glacier with a team of dogs, and reached a point of land beyond named Cape Constitution. But sickness and want of means prevented much from being done by travelling parties. Scurvy attacked the whole party during the second winter, although the Eskimo supplied them with fresh meat and were true friends in need. On May 17, 1855, Dr Kane abandoned the brig, and reached the Danish settlement of Upernivik on 6th August. Lieutenant Hartstene, who was sent out to search for Kane, reached Van Rensselaer Harbour after he had gone, but took the retreating crew on board on his return voyage.

Grinnell's expedition.

On July 10, 1860, Dr Hayes, who had served with Kane, sailed from Boston for Smith Sound, in the schooner "United States" of 130 tons and a crew of fifteen men.

His object was to follow up the line of research opened by Dr Kane. He wintered at Port Foulke, in  $78^{\circ} 17' N.$ , and about ten miles from Cape Alexander, which forms the eastern portal of Smith Sound. Dr Hayes crossed Smith Sound in the spring with dog-sledges, but his observations are not to be depended on, and it is very uncertain how far he advanced northwards on the other side. He returned to Boston on October 23, 1861.

Hall

The story of Charles Hall of Cincinnati, who was led to become an arctic explorer through his deep interest in the search for Franklin, has been told in the article devoted to him (vol. xi. p. 388). In his first journey (1860-62) he discovered the interesting remains of a stone house which Sir Martin Frobisher built on the Countess of Warwick Island in 1578. In his second expedition (1864-69) Hall by dint of the most unwearied perseverance at length reached the line of the retreat of the Franklin survivors, at Todd's Island and Peffer river, on the south coast of King William Island. He heard the story of the retreat and of the wreck of one of the ships from the Eskimo; he was told that seven bodies were buried at Todd Island; and he brought home some bones which are believed to be those of Lieutenant La Vescomte of the "Erebus." Finally, in 1871, he took the "Polaris" for 250 miles up the channel which leads northwards from Smith Sound. The various parts of this long channel are called Smith Sound, Kane Basin, Kennedy Channel, and Robeson Channel. The "Polaris" was beset in  $82^{\circ} 16' N.$  on 30th August; and her winter-quarters were in  $81^{\circ} 38' N.$ , called Thank God Bay. The death of Hall and the subsequent fortunes of the expedition have been described in the article above cited.

Norwegian explorers.

The Spitzbergen seas have been explored, in recent years, by Norwegian fishermen as well as by Swedish and German expeditions and by English yachtsmen. The Norwegian Spitzbergen fishery dates from 1820, but it is only in recent years that Professor Mohn of Christiania has watched over the voyages and carefully collected information from the captains. In 1863 Captain Carlsen circumnavigated the Spitzbergen group for the first time in a brig called the "Jan Mayen." In 1864 Captain Tobiesen sailed round North-East Land. In 1872 Captains Altmann and Nils Johnsen visited Wiche's Land, which was discovered by Captain Edge in 1617. In that year there were twenty-three sailing vessels from Tromsø, twenty-four from Hammerfest, and one from Vardø engaged in the arctic sealing trade. They average from 35 to 40 tons, and carry a dozen men. There were also eight vessels from Tromsø shark-fishing for cod-liver oil, and fifty from Hammerfest and Vardø. Since 1869 the Norwegians have extended their voyages to Nova Zembla. In that year Carlsen crossed the Sea of Kara and reached the mouth of the Obi. In 1870 there were about sixty Norwegian vessels in the Barents Sea, and Captain Johannesen circumnavigated Nova Zembla. In 1873 Captain Tobiesen was unfortunately obliged to winter on the Nova Zembla coast, owing to the loss of his schooner, and both he and his young son died of scurvy in the spring. Two years previously Captain Carlsen had succeeded in reaching the winter-quarters of Barents, the first visitor since 1597, an interval of two hundred and seventy-four years. He landed on September 9, 1871, and found the house still standing and full of interesting relics, which are now in the naval museum at the Hague.

Swedish expeditions.

Between 1858 and 1872 the Swedes sent seven expeditions to Spitzbergen and two to Greenland. All returned with valuable scientific results. That of 1864 under Nordenskiöld and Duner made observations at eighty different places on the Spitzbergen shores, and fixed the heights of numerous mountains. In 1868, in an iron steamer, the

"Sophia," the Swedes attained a latitude of  $81^{\circ} 42' N.$  on the meridian of  $18^{\circ} E.$ , during the month of September. In 1872 an expedition consisting of the "Polhem" steamer and brig "Gladen," commanded by Professor Nordenskiöld and Lieutenant Palander, wintered in Mussel Bay, on the northern shore of Spitzbergen. In the spring an important sledging journey of sixty days' duration was made over North-East Land. The expedition was in some distress as regards provisions owing to two vessels, which were to have returned, having been forced to winter. But in the summer of 1873 they were visited by Mr Leigh Smith, in his yacht "Diana," who supplied them with fresh provisions.

Dr Petermann of Gotha urged his countrymen to take their share in the noble work of polar discovery, and at his own risk he fitted out a small vessel called the "Germania," which sailed from Bergen in May 1868, under the command of Captain Koldewey. His cruise extended to Hinlopen Strait in Spitzbergen, but was merely tentative; and in 1870 Barou von Henglin with Count Zeil explored the Stor Fjord in a Norwegian schooner, and also examined Walter Thymen's Strait. After the return of the "Germania" in 1868 a regular expedition was organized under the command of Captain Koldewey, provisioned for two years. It consisted of the "Germania," a screw steamer of 140 tons, and the brig "Hansa" commanded by Captain Hegemann. Lieutenant Payer, the future discoverer of Franz Josef Land, gained his first arctic experience on board the "Germania." The expedition sailed from Bremen on the 15th June 1869, its destination being the east coast of Greenland. But in latitude  $70^{\circ} 46' N.$  the "Hansa" got separated from her consort and crushed in the ice. The crew built a house of patent fuel on the floe, and in this strange abode they passed their Christmas. In two months the current had carried them south for 400 miles. By May they had drifted 1100 miles on their ice-raft, and finally, on June 14, 1870, they arrived safely at the Moravian mission station of Friedriksthal, to the west of Cape Farewell. Fairer fortune attended the "Germania." She sailed up the east coast of Greenland as high as  $75^{\circ} 30' N.$ , and eventually wintered at the Pendulum Islands of Clavering in  $74^{\circ} 30' N.$  In March 1870 a travelling party set out, under Koldewey and Payer, and reached a distance of 100 miles from the ship to the northward, when want of provisions compelled them to return. A grim cape, named after Prince Bismarck, marked the northern limit of their discoveries. As soon as the vessel was free, a deep branching fjord was discovered in  $73^{\circ} 15' N.$  stretching for a long distance into the interior of Greenland. Along its shore are peaks 7000 and 14,000 feet high. The expedition returned to Bremen on September 11, 1870.

Lieutenant Payer was resolved to continue in the path of polar discovery. He and a naval officer named Weyprecht freighted a Norwegian schooner called the "Isbjörn," and examined the edge of the ice between Spitzbergen and Nova Zembla, in the summer of 1871. Their observations led them to select the route by the north end of Nova Zembla with a view to making the north-east passage. It was to be an Austria-Hungarian expedition, and the idea was seized with enthusiasm by the whole empire. Weyprecht was to command the ship, while Julius Payer conducted the sledge parties. The steamer "Tegethoff," of 300 tons, was fitted out in the Elbe, and left Tromsø on July 14, 1872. The season was exceptionally severe, and the vessel was closely beset near Cape Nassau, at the northern end of Nova Zembla, in the end of August. The summer of 1873 found her still a close prisoner drifting, not with a current, but in the direction of the prevailing wind. At length, on the 31st August, a

mountainous country was sighted about 14 miles to the north. In October the vessel was drifted within 3 miles of an island lying off the main mass of land. Payer landed on it, and found the latitude to be  $79^{\circ} 54' N.$  It was named after Count Wilczek, one of the warmest friends of the expedition. Here the second winter was passed. Bears were very numerous and as many as sixty-seven were killed, their meat proving to be a most efficient remedy against scurvy. In March 1874 Payer made a preliminary sledge journey in intense cold (thermometer at  $-58^{\circ} F.$ ). On 24th March he started for a more prolonged journey of thirty days. Payer found that the newly discovered country equalled Spitzbergen in extent, and consisted of two or more large masses—Wilczek Land to the east, Zichy Land to the west, intersected by numerous fjords and skirted by a large number of islands. A wide channel, named Austria Sound, separates the two main masses of land, and extends to  $82^{\circ} N.$ , where Rawlinson Sound forks off to the north-east. The mountains attain a height of 2000 to 3000 feet, the depressions between them being covered with glaciers; and all the islands even are covered with a glacial cap. The whole country was named Franz-Josef Land. Payer returned to the "Tegethoff" on 24th April; and a third journey was undertaken to explore a large island named after M'Clintock. It then became necessary to abandon the ship and attempt a retreat in boats. This perilous voyage was commenced on 20th May. Three boats stored with provisions were placed on sledges. It was not until 14th August that they reached the edge of the pack in  $77^{\circ} 40' N.$ , and launched the boats. Eventually they were picked up by a Russian schooner and arrived at Vardö on September 3, 1874. This great achievement is one of the most important connected with the north polar region that has been made in the present century, and will probably lead in due time to still further discoveries in the same direction.

One of the most interesting problems connected with the physical geography of the polar regions is the history and actual condition of the vast interior of Greenland, which is generally believed to be one enormous glacier. In 1867 Mr Edward Whymper carefully planned an expedition to solve the question, and went to Greenland, accompanied by Dr Robert Brown; but the season was too late, and progress was stopped, after going a short distance, by the breaking down of the dog-sledges. But Dr Brown made most valuable geological and natural history collections, chiefly in the neighbourhood of Disco, and still more valuable observations, the publication of which has added considerably to our knowledge. Dr Rink, for many years royal inspector of South Greenland and the most distinguished authority on all Greenlandic questions, has also visited the inland ice, and has given his stores of information to the world. The most important inland journey was undertaken by Professor Nordenskiöld in 1870, accompanied by Dr Berggren, the professor of botany at Lund. The difficulty of traversing the inland ice of Greenland is caused by the vast glacier being in constant motion, advancing slowly towards the sea. This movement gives rise to huge chasms and clefts, which from their almost bottomless depth close the traveller's way. The chasms occur chiefly where the movement of the glacier is most rapid, near the ice streams which reach the sea and discharge glaciers. Nordenskiöld, therefore, chose for a starting point the northern arm of a deep inlet called Auleitsivikfjörd, which is 60 miles south of the discharging glacier at Jakobshavn and 240 north of that at Godthaab. He commenced his inland journey on 19th July. The party consisted of himself, Dr Berggren, and two Greenlanders; and they advanced 30 miles over the glaciers to a height of 2200 feet above the sea.

Robert  
Brown.

Nordenskiöld in  
Greenland.

The gallant enterprises of other countries rekindled the zeal of England for arctic discovery; and in October 1874 the prime minister announced that an expedition would be despatched in the following year. The route by Smith Sound was selected because it gave the certainty of exploring a previously unknown area of considerable extent, because it yielded the best prospect of valuable scientific results, and because it offered, with proper precautions, reasonable security for a safe retreat in case of disaster.

Two powerful screw steamers, the "Alert" and "Discovery," were selected for the service, and Captain Narces was selected as leader. Commander Markham, who had made a cruise up Baffin's Bay and Barrow Strait in a whaler during the previous year, Lieutenant Aldrich, an accomplished surveyor, and Captain Feilden, R.A., as naturalist, were also in the "Alert." The "Discovery" was commanded by Captain Stephenson, with Lieutenant Beaumont as first lieutenant. The expedition left Portsmouth on the 29th May 1875, and entered Smith Sound in the last days of July. After much difficulty with the drifting ice Lady Franklin Bay was reached in  $81^{\circ} 44' N.$ , where the "Discovery" was established in winter-quarters. The "Alert" pressed onwards, and reached the edge of the palæocrystic sea, the ice-floes being from 80 to 100 feet in thickness. Leaving Robeson Channel, the vessel made progress between the land and the grounded floe pieces, and passed the winter off the open coast and facing the great polar pack, in  $82^{\circ} 27' N.$  Autumn travelling parties were despatched in September and October to lay out depôts; and during the winter a complete scheme was matured for the examination of as much of the unknown area as possible, by the combined efforts of sledging parties from the two ships, in the ensuing spring. The parties started on April 3, 1876. Captain Markham with Lieutenant Parr advanced, in the face of almost insurmountable difficulties, over the polar pack to the high latitude of  $83^{\circ} 20' 26'' N.$  Lieutenant Aldrich explored the coast-line to the westward, facing the frozen polar ocean, for a distance of 220 miles. Lieutenant Beaumont made discoveries of great interest along the northern coast of Greenland. The parties were attacked by scurvy, which, while increasing the difficulty and hardships of the work a hundredfold, also enhanced the devoted heroism of these gallant explorers. Captain Feilden was indefatigable in making collections, and was zealously assisted by all the officers. The expedition returned to England in October 1876. The "Alert" reached the highest northern latitude ever attained by any ship, and wintered further north than any ship had ever wintered before. The results of the expedition were the discovery of 300 miles of new coast-line, the examination of this part of the frozen polar ocean, a series of meteorological, magnetic, and tidal observations at two points farther north than any such observations had ever been taken before, and large geological and natural history collections.

In the same year 1875 Sir Allen Young undertook a voyage in his steam yacht the "Pandora" to attempt to force his way down Peel Sound to the magnetic pole, and if possible to make the north-west passage by rounding the eastern shore of King William Island. The "Pandora" entered Peel Sound on August 29, 1875, and proceeded down it much farther than any vessel had gone before since it was passed by Franklin's two ships in 1846. Sir Allen reached a latitude of  $72^{\circ} 14' N.$ , and sighted Cape Bird, at the northern side of the western entrance of Bellot Strait. But here an ice-barrier right across the channel barred his progress, and he was obliged to retrace his steps, returning to England on October 16, 1875. In the following year Sir Allen Young made

English  
expedi-  
tion of  
1875.

of the  
"Pan-  
dora."

another voyage in the "Pandora" to the entrance of Smith Sound.

Dutch  
expedi-  
tion—

Lieutenant Koolemans Beynen, a young Dutch officer, who had shared Young's two polar voyages, on his return successfully endeavoured to interest his countrymen in polar discovery. It was wisely determined that the first expeditions of Holland should be summer reconnaissances on a small scale. A sailing schooner of 79 tons was built at Amsterdam, and named the "Willem Barents." In her first cruise she was commanded by Lieutenant A. de Bruyne, with Koolemans Beynen as second, and she sailed from Holland on the 6th May 1878. Her instructions were to examine the ice in the Barents and Spitzbergen Seas, take deep-sea soundings, and make natural history collections. She was also to erect memorials to early Dutch polar worthies at certain designated points. These instructions were ably and zealously carried out. Beynen died in the following year, but the work he initiated has been continued. Every year from 1878 to 1884 the "Willem Barents" has made a polar voyage, and has brought back useful scientific results. In 1879 the Dutch succeeded in sighting the coast of Franz-Josef Land.

Gen-  
Booth  
and  
Mark-  
ham

In 1879 Sir Henry Gen-Booth, Bart., and Captain A. H. Markham, R.N., undertook a polar cruise in the Norwegian schooner "Isbjörn." They sailed along the west coast of Nova Zembla to its most northern point, passed through the Matotchkin Shar to the east coast, and examined the ice in the direction of Franz-Josef Land as far as 78° 24' N. Captain Markham brought home collections in various branches of natural history, and made useful observations on the drift and nature of the ice in the Barents and Kara Seas.

Leigh  
Smith

In 1880 Mr Leigh Smith, who had previously made three voyages to Spitzbergen, reached Franz-Josef Land in the screw steamer "Eira." It was observed that, while the Greenland icebergs are generally angular and peaked, those of Franz-Josef Land are vast masses quite flat on the top, like the Antarctic bergs, and from 150 to 200 feet high. The "Eira" sailed along the land to the westward, and discovered 110 miles of new coast line as far as the western extreme of the south side of Franz-Josef Land, whence the land trended north-west. A landing was effected at several points, and valuable collections were made in natural history. In the following year the same explorer left Peterhead on July 14; Franz-Josef Land was once more sighted on the 23d July, and the "Eira" reached a point farther west than had been possible in her previous voyage. But in August the ship was caught in the ice, was nipped, and sank. A hut was built on shore in which Mr Leigh Smith and his crew passed the winter of 1881-82; and on June 21, 1882, they started in four boats, to reach some vessels on the Nova Zembla coast. It was a most laborious and perilous voyage. They were first seen and welcomed by the "Willem Barents" on 2d August, and soon afterwards were taken on board the "Hope," a whaler which had come out for their rescue under the command of Sir Allen Young.

Norden-  
skiöld  
and the  
N.E.  
passage

Professor Nordenskiöld, when he projected the achievement of the north-east passage, was a veteran polar explorer, for he had been in six previous expeditions to Greenland and Spitzbergen. In 1873 he turned his attention to the possibility of navigating the seas along the northern coast of Siberia. Captain Wiggins of Sunderland was a pioneer of this route, and his voyages in 1874, 1875, and 1876 led the way to a trade between the ports of Europe and the mouth of the Yenisei river. In June 1875 Professor Nordenskiöld sailed from Tromsø in the "Proven," reached the Yenisei by way of the Kara Sea, and discovered an excellent harbour on the eastern side of its mouth, which was named Port Dickson, in honour of

Mr Oscar Dickson of Gothenburg, the munificent supporter of the Swedish expeditions. It having been suggested that the success of this voyage was due to the unusual state of the ice in 1875, Nordenskiöld undertook a voyage in the following year in the "Ymer" which was equally successful. By a minute study of the history of former attempts, and a careful consideration of all the circumstances, Professor Nordenskiöld convinced himself that the achievement of the north-east passage was feasible. The king of Sweden, Mr Oscar Dickson, and M. Sibiriakoff, a wealthy Siberian proprietor, supplied the funds, and the steamer "Vega" was purchased. Nordenskiöld was leader of the expedition, Lieutenant Palander was appointed commander of the ship, and there was an efficient staff of officers and naturalists, including Lieutenant Hovgaard of the Dutch and Lieutenant Bove of the Italian navy. A small steamer called the "Lena" was to keep company with the "Vega" as far as the mouth of the Lena, and they sailed from Gothenburg on the 4th July 1878. On the morning of 10th August they left Port Dickson, and on the 19th they reached the most northern point of Siberia and of the Old World, Cape Severo or Tchelyuskin, in 77° 41' N. On leaving the extreme northern point of Asia a south-easterly course was steered, the sea being free from ice and very shallow. This absence of ice is due to the mass of warm water discharged by the great Siberian rivers during the summer. On 27th August the mouth of the river Lena was passed, and the "Vega" parted company with the little "Lena," continuing her course eastward. Professor Nordenskiöld very nearly made the north-east passage in one season. Towards the end of September the "Vega" was frozen-in off the shore of a low plain in 67° 7' N. and 173° 20' W. near the settlements of the Tchukches. During the voyage very large and important natural history collections were made, and the interesting aboriginal tribe among whom the winter was passed was studied with great care. The interior was also explored for some distance. On July 18, 1879, after having been imprisoned by the ice for two hundred and ninety-four days, the "Vega" again proceeded on her voyage and passed Behring Strait on the 20th. Sir Hugh Willoughby made the first attempt in 1553. After a lapse of three hundred and twenty-six years, the north-east passage had at length been accomplished without the loss of a single life and without damage to the vessel. The "Vega" arrived at Yokohama on September 2, 1879.

In 1879 an enterprise was undertaken in the United States, with the object of throwing further light on the sad history of the retreat of the officers and men of Sir John Franklin's expedition, by examining the west coast of King William Island in the summer, when the snow is off the ground. The party consisted of Lieutenant Schwatka of the United States army and three others. Wintering near the entrance of Chesterfield Inlet in Hudson's Bay, they set out overland for the estuary of the Great Fish River, assisted by Eskimo and dogs, on April 1, 1879. They only took one month's provisions, their main reliance being upon the game afforded by the region to be traversed. The party obtained, during the journeys out and home, no less than five hundred and twenty-two reindeer. After collecting various stories from the Eskimo at Montreal Island and at an inlet west of Cape Richardson, Schwatka crossed over to Cape Herschel on King William Island in June. He examined the western shore of the island with the greatest care for relics of Sir John Franklin's parties, as far as Cape Felix, the northern extremity. The return journey was commenced in November by ascending the Great Fish River for some distance and then marching over the intervening

region to Hudson's Bay. The cold of the winter months in this country is intense, the thermometer falling as low as  $-70^{\circ}$ ,—so that the return journey was most remarkable, and reflects the highest credit on Lieutenant Schwatka and his companions. As regards the search little was left to be done after M'Clintock, but some graves were found, as well as a medal belonging to Lieutenant Irving of H.M.S. "Terror," and some bones believed to be his, which were brought home and interred at Edinburgh.

De Long. Mr Gordon Bennett, the proprietor of the *New York Herald*, having resolved to despatch an expedition of discovery at his own expense by way of Behring Strait, the "Pandora" was purchased from Sir Allen Young, and rechristened the "Jeannette." Lieutenant De Long of the United States navy was appointed to command, and it was made a national undertaking by special Act of Congress, the vessel being placed under martial law and officered from the navy. The "Jeannette" sailed from San Francisco on July 8, 1879, and was last seen steaming towards Wrangell Land on the 3d September. This land had been seen by Captain Kellett, in H.M.S. "Herald" on August 17, 1879, but no one had landed on it, and it was shown on the charts by a long dotted line. The "Jeannette" was provisioned for three years, but as no tidings had been received of her up to 1881, two steamers were sent up Behring Strait in search. One of these, the "Rodgers," under Lieutenant Berry, anchored in a good harbour on the south coast of Wrangell Land, in  $70^{\circ} 57'$  N. on the 26th August 1881. The land was explored by the officers of the "Rodgers" and found to be an island about 70 miles long by 28, with a ridge of hills traversing it east and west, the 71st parallel running along its southern shore. Lieutenant Berry then proceeded to examine the ice to the northward, and attained a higher latitude by 21 miles than had ever been reached before on the Behring Strait meridian, namely  $73^{\circ} 44'$  N. Sir R. Collinson, in 1850, had reached  $73^{\circ} 23'$  N. No news was obtained of the "Jeannette," but soon afterwards melancholy tidings arrived from Siberia. After having been beset in heavy pack ice for twenty-two months, the "Jeannette" was crushed and sunk on the 12th June 1881, in  $77^{\circ} 15'$  N. lat. and  $155^{\circ}$  E. long. The officers and men dragged their boats over the ice to an island which was named Bennett Island, where they landed on the 29th July. They reached one of the New Siberia Islands on the 10th September, and on the 12th they set out for the mouth of the Lena. But in the same evening the three boats were separated in a gale of wind. A boat's crew with Mr Melville, the engineer, reached Irkutsk, and Mr Melville set out in search of Lieutenant De Long and his party, who had also landed. The other boat was lost. Eventually Melville discovered the dead bodies of De Long and two of his crew on March 23, 1883. They had perished from exhaustion and want of food. The "Rodgers" was burnt in its winter quarters, and one of the officers, Mr Gilder, made a hazardous journey homewards through north-east Siberia.

Work of  
Danes in  
Green-  
land.

The Danes have been very active in prosecuting discoveries and scientific investigations in Greenland, since the journey of Nordenskiöld in 1870. Lieutenant Jensen made a gallant attempt to penetrate the inland ice in 1878, and Professor Steenstrup, with Lieutenant Hammer, closely investigated the formation of ice masses at Omenak and Jacobshavn. In 1883 an expedition under Lieutenants Holm and Garde began to explore the east coast of Greenland, the discovery of the outline of which was completed in 1879. In the summer of that year Captain Mourier, of the Danish man of war "Ingulf," sighted the coast from the 6th to the 10th of July, and was enabled to observe and delineate it from  $68^{\circ} 10'$  N. to  $65^{\circ} 55'$  N., being exactly the gap left between the discoveries of

Scoresby in 1822 and those of Graah in 1829. Lieutenant Hovgaard of the Danish navy, who accompanied Nordenskiöld in his discovery of the north-east passage, planned an expedition to ascertain if land existed to the north of Cape Tchelyuskin. He fitted out a small steamer called the "Dymplina" and sailed from Copenhagen in July 1882, but was unfortunately beset and obliged to winter in the Kara Sea. In 1883 Baron Nordenskiöld undertook another journey over the inland ice of Greenland. Starting from Auleitsivikfjord on 4th July, his party penetrated 84 miles eastward, and to an altitude of 5000 feet. The Laplanders who were of the party were sent on snow-shoes 143 miles further, travelling over a desert of snow to a height of 7000 feet. Results in physical geography and biology were obtained which will render this unparalleled journey memorable.

On September 18, 1875, Lieutenant Weyprecht, one of the discoverers of Franz-Josef Land, read a thoughtful and carefully prepared paper before a large meeting of German naturalists at Gratz on the scientific results to be obtained from polar research and the best means of securing them. He urged the importance of establishing a number of stations within or near the Arctic Circle, in order to record complete series of synchronous meteorological and magnetic observations. Lieutenant Weyprecht did not live to see his suggestions carried into execution, but they bore fruit in due time. The various nations of Europe were represented at an international polar conference at Hamburg in 1879, and at another at St Petersburg in 1882; and it was decided that each nation should establish one or more stations where synchronous observations should be taken from August 1882. This useful project was matured and executed. The stations were at the following localities round the Arctic Circle:—

Norwegians.....	Dosetop, Alten Fjord, Norway,	M. Aksel S. Steen.
Swedes.....	Ice Fjord, Spitzbergen,	Mr Ekholm.
Dutch.....	Dickson Harbour, mouth of Yenisei, Siberia,	Dr Smaller.
Russians.....	Sagastyr Island, mouth of Lena, Siberia,	Lieut. Jürgens.
	Möller Bay, Nova Zembla,	Lieut. Andreief.
Americans.....	Point Barrow, North America,	Lieut. May, U.S.A.
	Lady Franklin Bay, $61^{\circ} 44'$ N.	Lieut. Greely, U.S.A.
English.....	Great Slave Lake, Dominion of Canada,	Lieut. Dawson.
Germans.....	Cumberland Bay, west side of Davis Strait,	Dr Giese.
Danes.....	Godthaab, Greenland,	A. Paulsen.
Austrians.....	Jan Mayen, North Atlantic, $71^{\circ}$ N.,	Lieut. Wohlgenuth.

The whole scheme was successfully accomplished with the exception of the part assigned to the Dutch at Dickson Harbour. They started in the "Varna" but were beset in the Kara Sea and obliged to winter there. The "Varna" was lost, and the crew took refuge on board Lieutenant Hovgaard's vessel, which was also forced to winter in the pack during 1882-83.

The American stations commenced work in 1882. Greely. Lieutenant Greely's party consisted of two other lieutenants, of twenty sergeants and privates of the United States army, and of Dr Pavy, an enthusiastic explorer who had been educated in France, and had passed the previous winter among the Eskimo of Greenland. On August 11, 1881, the steamer "Proteus" conveyed Lieutenant Greely and his party to Lady Franklin Bay during an exceptionally favourable season; a house was built at the "Discovery's" winter-quarters, and they were left with two years' provisions. The regular series of observations was at once commenced, and two winters were passed without accident. Travelling parties were also sent out in the summer, dogs having been obtained at Disco. Lieutenant Lockwood made a journey along the north coast of Greenland, and reached a small island in  $83^{\circ} 24'$  N. and  $40^{\circ} 46'$  W. Dr Pavy and another went a short distance beyond the winter-quarters of the "Alert," and two trips were made into the interior of Grinnell Land. The coast on the western side was reached, and a large lake was discovered near Discovery Harbour. The chief value of

the work of Lieutenant Greely's party will consist in the synchronous observations taken during 1882. As no steamer arrived in the summer of 1883—though relieving vessels were despatched both in 1882 and in 1883—Lieutenant Greely started from Lady Franklin Bay with his men on the 9th August, expecting to find a vessel in Smith Sound. On the 21st October they were obliged to encamp at Cape Sabine, on the western shore of Smith Sound, and build a hut for wintering. A few depôts were found, which had been left by Sir George Nares and Lieutenant Beebe, but all was exhausted before the spring. Then came a time of indescribable misery and acute suffering. The poor fellows began to die of actual starvation; and, when the relieving steamers "Thetis" and "Bear" reached Cape Sabine, Lieutenant Greely and six suffering companions were found just alive. If the simple and necessary precaution had been taken of stationing a depôt ship in a good harbor at the entrance of Smith Sound, in annual communication with Greely on one side and with America on the other, there would have been no disaster. If precautions proved to be necessary by experience are taken, there is no undue risk or danger in polar enterprise.

There is now no question as to the value and importance of polar discovery, and as to the principles on which expeditions should be sent out. Their objects are exploration for scientific purposes and the encouragement of maritime enterprise. The main principles have been briefly and clearly stated by Lieutenant Weyprecht:—(1) arctic research is of the highest importance for a knowledge of nature's laws; (2) geographical research is valuable in proportion as it opens the field to scientific research generally; (3) the north pole has, for science, no greater significance than any other point in the higher latitudes. Lieutenant Weyprecht thus contends, as the council of the Royal Geographical Society has contended for years, that the attainment of the highest possible latitude or of the pole itself is not the object to be sought, but the exploration of the unknown area with a view to scientific results.

In planning a new polar expedition on an adequate scale it will be necessary to profit by the lessons of experience. This experience may be summed up in a few words. Any advanced ship or party must have a depôt ship to fall back upon which is within reach, and also in communication with the outer world. This makes disaster on a large scale, humanly speaking, impossible. Every precaution that medical science can suggest must be taken against scurvy. An advancing expedition must always follow a coast line, because an entry into the drifting pack entails failure and probably loss of the ship. The coast-line should trend north with a westerly aspect, because a general motion of the sea towards the west causes the ice to set in that direction, unless deflected from purely local causes. Hence there are usually open lanes of water along the west sides of polar lands at some time of the navigable season, while the eastern sides are usually closed with ice. These well-established canons point to the western side of Franz-Josef Land as the next region to be explored.

*Physical Geography of the North Polar Region.*—Our ignorance of about 9,000,000 square miles within the north polar circle, out of a total area of 8,291,553, detracts us from the possibility of considering the physical geography of the polar region as a whole. We can merely take stock of the isolated facts which our limited knowledge enables us to register.

**Temperature.**—As the physical condition of the whole area is mainly affected by the movements and positions of the ice masses, the temperature and the circumstances which affect it, become the first and most fundamental elements for consideration. An examination of Dove's isothermal charts shows that the isotherms about the pole form ellipses tending to arrange themselves between two poles of cold, one in North America and the other in eastern Siberia. The mildest winters appear to be in the narrows of Behring Strait and the Spitzbergen seas. These temperatures appear to be mainly

influenced by the extent of frozen land or fixed ice on the one hand and the neighbourhood of open water and moving ice on the other. The following table shows the mean temperatures for the summer months, winter months, and whole year, at various stations in the archipelago north of the American continent:—

Expedition	Locality	Latitude and Longitude	Summer Months (June, July, Aug.)	Winter Months (Dec., Jan., Feb.)	Year
McClure	Beaufort Strait	74° N. 124° W.	+38	-37	+1
Peary	North Pole	84° 55' N. 119° 50' W.	+34	-37	+1
Greenland	Cape York	74° 45' N. 54° 50' W.	+41	-34	+3
Peary	North Polar Sea	71° 15' N. 97° W.	+34	-37	+1
Peary	North Pole	81° 25' N. 119° 50' W.	+34	-37	+1

In the Great Slave Lake in North America, Sir John Richardson found the mean of the three summer months to be +45°, of the three winter months -5° 8', and of the year +4°. On the west coast of Greenland the climate of the southernmost part resembles that of Iceland or the northern shores of Norway. It exhibits a gradually decreasing temperature throughout the whole of its extent to the north. The annual mean temperature at the southernmost station of Julianahab is +45°, and at the northernmost of Upernivik -16°. The mean temperature of the three summer months for Julianahab is +45° and for Upernivik +45°; for the three winter months respectively -45° and -7°. The lowest temperature ever known at the Danish Greenland stations occurred at Upernivik and was -47°. Further north on the west coast the "North Star" in 1851-52 observed the temperature for the year in Westport Sound (lat. 76° 00' N.). For the three summer months the mean was +47° 8', for the winter months -6° 8', and for the year +4° 8'. The most northern observations ever taken for a complete year were those of H.M.S. "Albatross" at Floberg Beach in 52° 57' N. Synoptic observations were taken by H.M.S. "Discovery" in Lady Franklin Bay, lat. 52° 44' N. The results were as follows:—

Station	Latitude	Summer	Winter	Year
"Albatross".....	52° 57' N.	+34	-37	+1
"Discovery".....	51° 44' N.	+33	-37	+1

The minimum temperatures were -70°, registered at Floberg Beach in March, and -70°, at Lady Franklin Bay in the same month. These temperatures can be compared with the observations taken at Morsel Bay, on the north coast of Spitzbergen, by Nordenskiöld (lat. 79° 54' N.), and on the south coast of Franz-Josef Land by Weyprecht and Leigh Smith. At these stations the winters are less severe on account of the closer proximity of open water. In Franz-Josef Land the minimum in the winter months was -45°, and the mean was -55°; in May the mean was +25°. The climate on the coast of Siberia was registered at the winter quarters of the "Vega" in 57° 5' N., the mean temperature of the three winter months being -10°, minimum -51°, and the mean of the three summer months +25°; but the Siberian cold is far more intense inland.

The direction of the winds affects the temperature and the movements of ice, but no general remarks upon them can be usefully made until our knowledge of the polar area is more complete. One of the most interesting features in polar winds is the instability of the temperatures caused by them over certain areas during the winter months. At Janetsbørn in Greenland, the mean temperature in February was +16° in one year (1872), and -25° in another (1883), a difference of 41°. It was remarked that great rises in the winter temperatures occurred at a time when the wind was blowing from the inner glacier. This wind often turns into a sudden gale. Greenland is surrounded by regions which have extremely different winter temperatures. While on one side there is the intense cold of Arctic America and the Fanny Islands, on the other, to the east-south-east, there is the warm temperature caused by the Gulf Stream: so that the Greenland climate is at all times dependent on the direction of the winds. All winds from south through west to north-west bring cold weather, but the east and south-east winds raise the temperature. The hot south-east winds of Greenland are caused in the same way as the "föhn" of the Alps. The interior glacier of Greenland rises to a height of at least 7000 feet. A warm wind from the Atlantic surrounded with moisture could afford to lose considerably by cooling on its journey of 400 miles over the lofty ice deserts of Greenland, and yet arrive on the west coast with a comparatively high temperature. The influence of the Greenland föhn extends over a wide area. In 1875 there was a great rise of temperature at the Danish stations of Greenland; and Sir George Nares observed the same phenomenon, at nearly the same time, at his winter quarters in 52° 17' N. In Franz-Josef Land there are also great rises of temperature during the winter, with southerly winds accompanied

by heavy falls of snow, as these winds come direct from expanses of open water caused by the current from the Atlantic.

Ice.

Sea water, in the process of congelation, expels the salt, and its freezing point is about 28°. The ice first forms in thin, irregular flakes called "sludge," and when this is compact enough to hold snow it is known as "brash." Gathered into rounded masses it becomes "pancake ice," and soon it becomes thicker. The first thin covering is called by the whalers "bay ice." A "floe" is a sheet of ice the limits of which are visible. An "ice-field" differs from a floe in being so extensive that its limits cannot be seen. "Pack ice" consists of broken floes forced together by the wind or currents. When the pack is loosened and scattered by a wind from an opposite direction the pieces are called "sailing ice." The greatest thickness attainable by ice in one season is about 7 feet. The results of observations made by Sir George Nares in 82° 17' N. on the west side of Greenland and by Captain Koldewey on the east side in 74° 30' N. were identical, namely 6 feet 7 inches. Old ice is believed to become thicker in a second winter, and even to attain a thickness of 10 feet. In the paleocrycstic sea there are floes from 80 to 100 feet thick, but these must be considered rather as sea-glaciers, formed by accumulations of snow on the ice year after year; and the smaller pieces broken from them have been very appropriately named *floebergs*. These mighty floes are sea-borne glaciers, perpetually wasted beneath and restored from above.

Icebergs.

Icebergs are only met with where there are great discharging glaciers on the land, or in currents leading from them. Greenland is the principal mother of icebergs. This immense mass covers an area of about 512,000 square miles, and has 3400 miles of coast-line. It is indented by deep channels or fjords, often extending more than 60 miles, with many islands and rocks along the coast. The whole of the interior is believed to be capped by an enormous glacier always moving towards the coast, and at certain points reaching the sea where masses break off in the shape of icebergs. These icebergs rise to a height of from 60 to 300 feet above the sea, with a circumference from several hundred to several thousand yards; and from seven to eight times the bulk seen above water is submerged, so that the weight of a large berg is millions of tons. When pieces break off from a parent iceberg the process is called "calving," and the pieces are "calf ice." Recent observation of one of the principal discharging glaciers of Greenland shows it to be 920 feet thick, and 18,400 feet wide, and that it advances at a rate of 47 feet a day during the summer season. In Spitzbergen and Nova Zembla there are much smaller glaciers discharging smaller berg pieces. The Franz-Josef Land glaciers produce large flat-topped icebergs, which do not, however, float southwards.

Currents.

The movements of the polar seas are influenced by the currents of seas and rivers which are constantly flowing northwards, and by ice-laden counter-currents which press through every strait and channel in the opposite direction. On the fringe of land forming the northern shores of Asia and America are the mouths of several great rivers. Of the Siberian rivers the Obi, with its affluent the Irtysh, has a basin covering 60,000 square miles, the Yenisei 50,000, and the Lena 40,000; but these areas are almost entirely within the temperate zone. In America the rivers Mackenzie, Coppermine, and Great Fish (or Back) also pour their waters into the polar sea. The enormous volume of warm water which these rivers send into the ocean drives the heavy ice from the coast and, owing to the influence which the rotatory motion of the earth exercises, receives an easterly direction along the coast. Behring Strait is too narrow and too shallow to admit of any large flow from the Pacific, still there is a warm current which keeps the heavy ice at some distance and also flows easterly, its influence being felt beyond Point Barrow. The Norwegian current, usually considered to be a continuation of the Gulf Stream, conveys a large volume of water northwards along the coasts of Norway and Lapland, and keeps the ice at a distance from that shore throughout the winter. The polar currents flow southwards in the direction of the two great openings by Davis Strait and the sea on the east coast of Greenland, but the whole body appears eventually to find its way southwards by the former outlet. The current flowing south along the east coast of Greenland brings with it immense quantities of heavy ice, and when it reaches the south point of the land it turns westward and northward round Cape Farewell, until about 64° N., when it unites with the current coming from Baffin's Bay, and the united current, with its enormous quantity of ice and icebergs, flows south along the Labrador coast to Newfoundland. The other polar current flows southwards through all the channels and straits among the Parry Archipelago, and through Fury and Hecla Strait, down Baffin's Bay and Davis Strait.

Paleo-crycstic sea.

The observations of various explorers lead to the conclusion that these outlets are insufficient to carry off the great harvests of ice, and that, in one part of the polar region, it continues to accumulate and form sea-borne glaciers. Collinson observed this formation off the coast of North America. McClure found it along the west coast of Banks Island, while McClintock and Meacham traced it along the western side of Prince Patrick Island. "The surface of the floes resembles rolling hills, some of them a hundred feet from

base to summit,—aged sea ice which may be centuries old, and from want of an outlet likely to increase yet in thickness to an unlimited degree. The accumulated action of repeated thaws and falls of snow on the upper surface gives it a peculiar hill and dale appearance." The same ice was found by Nares's expedition along the northern coast of Grant Land and Greenland 80 to 100 feet thick. A branch from it flows down McClure Strait and McClintock Channel until it impinges upon the north-west coast of King William Island. This is what Professor Haughton calls "the ice barrier placed in this position by the still waters caused by the meeting of the Atlantic and Pacific tides."

The physical aspects of polar lands are much influenced by their geological formation. The Greenland coast consists mainly of gneiss, mica schist, hornblende schist, and syenite pierced by granite veins. In this formation are found the stearite used by the natives to make lamps, the cryolite of Ivigtut in the south, and the plumbago at Upernivik. North of 68° N. a flow of basalt extends across the Noursoak peninsula and Disco Island, covering an area of about 7000 square miles, and rising to a height of 6000 feet. With these trap rocks are associated the Miocene and Cretaceous beds. The Cretaceous rocks have only been found in the Omenak-fjord in 70° N.; while the Miocene formation is confined to the shores of the Waigat Strait, between Disco and the mainland, underlying the trap. Coal beds appear in several places along the shore, and very interesting remains of fossil plants have been discovered. At the termination of Igalliko-fjord in 61° N. a compact red sandstone is found. Pendulum Islands on the east coast are Oolitic. But with these exceptions the whole mass of Greenland is granitic or gneissose. The opposite side of Baffin's Bay is of the same character, as well as both sides of Peel Sound. The Parry Islands are partly Silurian and partly of the Carboniferous period. The eastern part, including North Somerset and Prince of Wales Land (except the shores of Peel Sound) and Cornwallis Island are of Silurian formation, with fossils, equivalents to the Wenlock and Dudley groups. This formation extends westward from Boothia Felix and King William Island over Prince Albert Land and the southern half of Banks Island. The southern halves of Bathurst, Melville, and Prince Patrick Islands, and the northern half of Banks Island consist of Lower Carboniferous sandstones with beds of coal, while Grinnell Land and the northern halves of Bathurst, Melville, and Prince Patrick Islands are Carboniferous limestone. Lias fossils (ammonites) were found at one place on the east side of Prince Patrick Island in 76° 20' N. Sherard Osborn also found the vertebra of a huge saurian (*Teleosaurus*) at the north-west extreme of Bathurst Island, probably of the Lower and Middle Oolitic period.

Ellesmere Land, on the western side of Smith Sound, consists of gneiss rising to heights of 2000 feet which underlie Miocene rocks at Fort Foulke. Farther north the gneiss continues with stratified black slates having a very high and often vertical dip. In 82° 33' N. these slates give place to a series of quartzites and grits rising to elevations of 2000 and 3000 feet. Silurian limestones are found on the shores of Kennedy Channel up to Cape Tyron on the Greenland side. Carboniferous limestone occurs on the north coast of Grant Land, as far west as Clements Markham Inlet, rising to a height of 2000 feet. Near Lady Franklin Bay in 81° 46' N. a deposit of coal of the Miocene period was discovered, with a fossil flora including thirty species of plants—pines, birch, poplar, elm, and hazel. The whole of this land to the north of Baffin's Bay is slowly rising.

Spitzbergen and Nova Zembla are also composed mainly of primitive rocks. In northern Spitzbergen there are also Miocene beds with a fossil flora closely allied to that of Lady Franklin Bay, and some fossils of the Lias period. The geological characters of Franz-Josef Land and Spitzbergen are closely allied. The predominant rock is dolerite, a kind of gneiss.

The "tundra" of Siberia is a wide belt of land intervening between the line of forest and the polar shores, and intersected by the great rivers. It is frozen for immense depths below the surface, and here the remains of mammoths, generally in great landslips along the river banks, have been found. But their fossil ivory occurs in greatest quantity in the New Siberia group. On these islands also occur the "wood-hills" consisting of horizontal sandstone beds alternating with strata of bituminous tree stems, heaped on each other to the top of the hill. Ammonites of the Lias period are also found there.

In the polar regions the line of forest seldom reaches to the Arctic Circle; low birches and willows and shrubs bearing berries occur in the south of Greenland, but farther north the creeping willow alone forms wood. There are 762 flowering plants, and 925 cryptogams within the Arctic Circle, making a total of 1687 plants. Lapland contains by far the richest arctic flora, amounting to three-fourths of the whole, while three-fifths of the species found in Arctic Asia and America also belong to Lapland. In the European arctic district 616 flowering plants have been collected, in Arctic Asia 233, in Arctic America eastward of the Mackenzie 379, and westward of that river 364, and in Greenland 207. The most arctic plants of

was confirmed by Mr Bransfield, the master of H.M.S. "Andromache," flag-ship on the west coast of South America, who further discovered another portion named Bransfield Land. Further coast-line was sighted by the French expedition under Dumont d'Urville in 1838, who named it Prince de Joinville and Louis Philippe Land.

The South Orkneys were discovered by Captain George Powell, in the sloop "Dove," on October 6, 1821. Mr Weddell, R.N., with the sailing vessels "Jane" and "Beaufoy," penetrated as far south as 74° 15' S. on the 20th February 1823.

In the early part of this century Messrs Enderby began to send vessels to the Antarctic regions for the whale fishery, which made several discoveries. The brig "Tula" of 148 tons and cutter "Lively" left London in July 1830 under the command of Mr John Biscoe, R.N., on a sealing voyage, but with special instructions to endeavour to make discoveries in high southern latitudes. In February 1831 land was discovered in longitude 47° 20' E. and latitude 65° 57' S., which Biscoe named Enderby Land, in honour of his employers. He did not, however, get nearer to it than 20 or 30 miles. In February 1831 Biscoe again discovered land in 67° 1' S. lat. and 71° W. long., to which he gave the name of Adelaide Island. It proved to be the westernmost of a chain of islands fronting a high continuous coast, since called Graham's Land. A few days afterwards Captain Biscoe succeeded in landing on Adelaide Island. In 1833 Captain Kemp, in the sealing schooner "Magpie," discovered another point of the land to the eastward, which doubtless forms part of Enderby Land.

Messrs Enderby sent out another expedition of discovery in 1838, consisting of the "Eliza Scott" of 154 tons, commanded by Mr John Balleny, and the "Sabrina" cutter of 54 tons, under Mr Freeman. In February 1839, when on about the 163d E. meridian, they sighted high land in 66° 30' S. On the 12th, Captain Freeman managed to get on shore, but the cliffs were perpendicular, and the valleys were filled with ice. The discovery proved to be a group of volcanic islands, one of them rising to a beautiful peak estimated at 12,000 feet above the sea, named Freeman Peak. Sabrina Island was discovered in March 1839. The other group received the name of the Balleny Islands. The Auckland Islands were ceded to Messrs Enderby in 1849, and a whaling establishment was formed there under good auspices.

In 1839 the French expedition under Dumont d'Urville proceeded south from Tasmania and discovered two small islands on the Antarctic Circle named "Terre Adélie" and "Côte Clarie." At the same time Commander Wilkes of the United States expedition made a cruise to the southward and mapped a large tract of land in the latitude of the Antarctic Circle for which he claimed the discovery. But as a portion of it had already been seen by Balleny, and the rest has since been proved not to exist, the claim has not been admitted.

The English Antarctic Expedition of 1839-43 was undertaken mainly with a view to magnetic observations, and the determination of the position of the south magnetic pole. Two old bomb vessels, the "Erebus" and "Terror," were fitted out under the command of Captain (afterwards Sir James) Ross, with Captain Crozier in the "Terror." Dr Joseph D. Hooker accompanied the expedition as naturalist. Leaving Chatham in September 1839, the two vessels first proceeded to the Cape, and went thence southwards to Kerguelen Island, which was reached in May 1840, and carefully surveyed. In August Sir James Ross established a magnetic observatory at Hobart Town. The cruise for the second season was commenced from Tasmania in November 1840. The Auckland Islands and Campbell Island were first visited and surveyed, and on New Year's Day 1841 the Antarctic Circle was crossed in about 172° E. A few days afterwards the two vessels were beset in the pack and began perseveringly boring through it. By January 10th they succeeded and were clear of ice in 70° 23' S., and next day land was sighted, rising in lofty peaks and covered with perennial snow. That day Ross passed the highest latitude reached by Cook (71° 15' S.). On a nearer approach to the land, there was a clear view of the chain of mountains with peaks rising to 10,000 feet, and glaciers filling the intervening valleys and projecting into the sea. The south magnetic pole was calculated to be in 76° S. and 145° 20' E., or about 500 miles south-west from the ship's position. The land interposed an insuperable obstacle to any nearer approach

to it. Captain Ross landed with great difficulty, owing to the strong tide and drifting ice, on a small island near the shore, named Possession Island, in 71° 56' S. and 171° 7' E. Innumerable myriads of penguins covered the surface, but no vegetation was seen. Next morning there was a southerly gale which moderated, and on 18th January they were again sailing south in an unexplored sea. On the 23d they were in 74° 20' S.; and thus passed the most southern latitude previously reached (by Captain Weddell in 1823). Sailing along the newly discovered coast, Captain Ross landed after much difficulty on an island named after Sir John Franklin in 76° 8' S. On the 27th they came in sight of a mountain 12,400 feet above the sea, which proved to be an active volcano emitting flame and smoke in great profusion. It was named Mount Erebus, and an extinct volcano to the eastward 10,900 feet high was named Mount Terror. Along the coast as far as the eye could reach to the eastward there was a perpendicular cliff of ice from 150 to 200 feet high, perfectly level at the top, and without any fissures or promontories on its smooth seaward face. Nothing could be seen above it except the summits of a lofty range of mountains extending to the southward as far as 79° S. To this range the name of Parry was given. The most conspicuous headlands under Mount Erebus were named Capes Crozier and Bird. Captain Ross then sailed eastward along the marvellous wall of ice, in 77° 47' S. to 78° S. This ice barrier was calculated to be 1000 feet thick, and it was followed for a distance of 450 miles without a break. The winter was now approaching, young ice was beginning to form, but luckily a strong breeze enabled them to force their way through it. The whole of the great southern land discovered by Sir James Ross was named Victoria Land.

In returning to Hobart Town the expedition visited the Balleny Islands, and searched in vain for the land which Captain Wilkes had laid down on his chart.

In November 1841 the "Erebus" and "Terror" again shaped a southerly course, entered the pack ice on December 18th, and once more crossed the Antarctic Circle on New Year's Day. The navigation through a belt of ice 800 miles broad was extremely perilous. At length on 1st February 1842 a clear sea was in sight, and they proceeded to the southward in 174° 31' W. On the 22d they were surrounded by numerous lofty icebergs aground, and at midnight the Great Ice Barrier was sighted and its examination recommenced in 77° 49' S. Next day the expedition attained a latitude of 78° 11' S., by far the highest ever reached before or since. After escaping imminent dangers in navigating through chains of huge icebergs, Captain Ross took his ships northward, and wintered at the Falkland Islands.

In December 1842 the expedition sailed from Port Louis on the third visit to the south polar region, seeing the first iceberg in 61° S. On the 28th the ships sighted the land named after the Prince de Joinville by Dumont d'Urville, and the southern side of the South Shetlands was discovered and surveyed. During February about 160 miles of the edge of the pack were examined, on March 11th the Antarctic Circle was recrossed for the last time, and the expedition returned to England in September 1843. Thus after four years of most diligent work, this ably conducted and quite unparalleled voyage to the south polar regions came to an end.

In 1845 a merchant barque, the "Pagoda," was hired at the Cape, in order that magnetic observations might be completed south of the 60th parallel, between the meridians of the Cape and Australia. The ship's progress was stopped by an impenetrable pack in 68° S. The magnetic work was, however, completed.

H.M.S. "Challenger," the exploring ship commanded by Captain Nares, arrived at Kerguelen Island on the 6th January 1874, where surveys were made, and the island was thoroughly examined by the naturalists of the expedition. Two islands, named Heard and McDonald, were also visited, which had been discovered in November 1853 by Captain Heard of the American ship "Oriental," owing to the practical application of the problem of great circle sailing. There is in fact a group of islands about 240 miles from Kerguelen. In February the "Challenger" ran south before a gale of wind and the first iceberg was sighted on the 11th in 60° 52' S. It was 200 feet high and about 700 long. On the 19th the ship was at the edge of a dense pack in 65° 42' S.; and on the 4th March they bore up for Australia. Several deep-sea soundings were taken, the greatest depth being 1975 fathoms. The route of the "Challenger" was much the same as that of the "Pagoda" in 1845, but more to the north. With it ends the somewhat meagre record of voyages across and towards the Antarctic Circle. (C. R. M.)

POLE, REGINALD (1500-1558), generally known as Cardinal Pole, was born at Stourton Castle, Staffordshire, March 3, 1500. He was the son of Sir Richard Pole and Margaret, countess of Salisbury. Designed from early

youth for the church, he was educated in the Carthusian monastery at Sheen, and at Magdalen College, Oxford. He was admitted to deacon's orders at the age of sixteen, and at once received high preferment, holding, among other

markings. Its skull is rough, strongly ridged, and altogether of a far more powerful type than those of the stoats, weasels, or martens; the skull of the female is very much smaller and lighter than that of the male. Its fur is long, coarse, and of comparatively small value, and changes its colour very little, if at all, at the different seasons of the year.

The distribution and habits of the common polecat have been well described by Blasius in his *Säugethiere Deutschlands*, and the following is an abstract of his account. The polecat ranges over the greater part of Europe, reaching northwards into southern Sweden, and in Russia to the region of the White Sea. It does not occur in the extreme south, but is common everywhere throughout central Europe. In the Alps it ranges far above the tree-line during the summer, but retreats in winter to lower ground. In fine weather it lives either in the open air, in holes, fox-earths, rabbit-warrens, under rocks, or in wood-stacks; while in winter it seeks the protection of deserted buildings, barns, or stables. During the day it sleeps in its hiding place, sallying forth at night to plunder dovecots and hen-houses. It climbs but little, and shows far less activity than the marten. It feeds ordinarily on small mammals, such as rabbits, hamsters, rats, and mice, on such birds as it can catch, especially poultry and pigeons, and also on snakes, lizards, frogs, fish, and eggs. Its prey is devoured only in its lair, but, even though it can carry away but a single victim, it commonly kills everything that comes in its way, often destroying all the inhabitants of a hen-house in order to gratify its passion for slaughter. The pairing time is towards the end of the winter, and the young, from three to eight in number, are born in April or May, after a period of gestation of about two months. The young, if taken early, may be easily trained, like ferrets, for rabbit-catching. The polecat is very tenacious of life and will bear many severe wounds before succumbing; it is also said to receive with impunity the bite of the adder. Its fetid smell has become proverbial. To this it is indebted for its generic name *Putorius* (derived, as are also the low Latin *putacius*, the French *putois*, and the Italian *puzzola*, from *puteo*), as well as the designation *foumart* (i.e. foul marten), and its other English names *fitchet*, *fitchew*. Attempts to account for the first syllable of the word *polecat* rest entirely on conjecture.

The other species of the polecat group are the following:—

The Siberian Polecat (*Putorius eversmanni*), very like the European in size, colour, and proportions, but with head and back both nearly or quite white, and skull more heavily built and sharply constricted behind the orbits, at least in fully adult individuals. It inhabits the greater part of south-western Siberia, extending from Tibet into the steppes of south-eastern European Russia.

The Black-footed or American Polecat (*Putorius nigripes*), a native of the central plateau of the United States, and extending southwards into Texas. It is very closely allied to the last species, but has nevertheless been made the type of a special sub-genus named *Cynomys*, or "King of the Prairie Marmots," a name which expresses its habit of living in the burrows of, and feeding upon, the curious prairie marmots (*Cynomys*) of the United States. An excellent account of this species may be found in Dr Elliott Coues's *Fur-bearing Animals of North America*.

Lastly, the Mottled Polecat (*Putorius sarmaticus*), a rare and peculiar species occurring in southern Russia and south-western Asia, extending from eastern Poland to Afghanistan. It differs from the other polecats both by its smaller size and its remarkable coloration, the whole of its upper parts being marbled with large irregular reddish spots on a white ground, and its underside, limbs, and tail being deep shining black. Its habits, which seem to be very much those of the common polecat, have been studied in Kandahar by Captain Thomas Hutton, who has given a vivid description of them in the *Journal of the Asiatic Society of Bengal* for 1845.

POLEVOY. See RUSSIAN LITERATURE.

**POLICE.** The branch of criminal justice which comprises a methodical system for the prevention and detection of crime is commonly known by the name of "Police." With the system having these objects is combined the execution of many duties not strictly involved in the popular definition of crime, but materially affecting the security and convenience of the public. Bentham, more comprehensively, says that police is in general a system of precaution either for the prevention of crime or of calamities. It is destined to prevent evils and provide benefits. The system for the attainment of these objects and the introduction and establishment of that system in the United Kingdom form the main subject of this article; some account will afterwards be given of the police in other states.

In this view the definition and use of the word "police," as meaning the regulation and government of the city and country in relation to the inhabitants, are not sufficiently close. When Blackstone says that by the public police and economy he means "the due regulation and domestic order of the kingdom, whereby the individuals of the state, like members of a well governed family, are bound to conform their general behaviour to the rules of propriety, good neighbourhood, and good manners, and to be decent, industrious, and inoffensive in their respective stations," the definition is capable of an interpretation at once too wide and too narrow for the present purpose. It is vain to look for an accurate description of police, as a system, in writers of a period when the thing sought for had no existence. The system is of recent growth, and it is necessarily more associated with personal instruments for the attainment of objects than with the objects to be attained. An observation of Gibbon, referring to the ædiles and quaestors of the Roman empire, that officers of the police or revenue easily adapt themselves to any form of government, correctly presents the idea of distinctive personal elements. A system of police administration includes neither the making of the law nor the law itself. Officers of police are neither legislators nor (in the usual sense) magistrates. They are the instruments by which conformity to the rules of the commonwealth is attained.

Apart from the repression of crime as generally understood, it is plain that, at least in crowded cities, a power ought to exist for the suppression of noise and disorder, the regulation of locomotion and traffic, the correction of indecency, and the prevention of a numerous class of annoyances and impositions which can only be restrained by cognizance being taken of them at the instant. To these may be added a number of petty disputes the immediate settlement of which tends materially to the public peace. Over such subjects as these it is obviously for the general advantage the police should have a summary control. Any apprehension of danger to liberty can only be founded on its abuse and not upon its proper exercise.

The employment of persons in these various duties, as well as in the prevention and detection of graver matters of crime, constitutes a division of state labour. Therefore, while it is perfectly correct to speak of the various legislative and other measures for good order as "matters of police," the organization and management of the police forces constitute a distinct subject.

The essential features of the established police system, alike in Great Britain and in foreign states, in cities and towns as in countries and village communities, comprise the following matters:—

I. A body of persons in relation to the state enforcing obedience to the criminal law, the prevention and detection of crime, and the preservation of order, over a defined area, generally divided and subdivided for the purpose of distribution and immediate government of the force, but having one jurisdiction throughout.

II. The division of that force into classes of various rank, comprising, in general, in ascending order, constables, sergeants, inspectors, and superintendents (or their equivalents),—the constables being the most numerous and themselves divided into classes.

III. General control of the entire body by heads, whether styled commissioners or chiefs, having power to make regulations for the government of the force, subject in turn to the control of state authorities.

IV. Patrol day and night of the streets, roads, and public places,—the "beats" and "tours of duty" of constables being prescribed by regulations, and actual performance and compliance being secured by the sergeants and inspectors.

V. The payment of the force, including establishment charges, out of public funds provided for the purpose.

Relation  
to the  
state.

In dealing with these subjects as nearly as may be in the order indicated, the relationship of the police force to the state is of primary importance. A general control by the executive Government of a state of the police forces, for the legitimate objects for which they are established, seems essential. In Great Britain every member of the force, from an ordinary constable upwards, stands in the direct position of a servant of the crown. On admission he makes a promissory declaration (recently substituted for an oath) that he will serve the sovereign; and it is upon the fact that a police constable has the powers, duties, and privileges of a peace officer of and for the crown that many of the incidents of his service depend, although the immediate power of dismissal is vested in heads of a force, who are orders he is bound to obey.

The state employs the police forces for the public welfare only. "There is not in England," remarked the late Chief-Justice Cockburn, "any more than in America, any system of espionage or secret police to pry into men's secret action or to obtain information for the Government by underhand and unworthy means." The truth of this is exemplified in the present position of police administration in the metropolitan police district of England acting under the immediate control of the secretary of state. The fear expressed, and no doubt felt, on the first establishment of a regularly organized system of police, that the freedom of holding meetings and the utterance of opinion at them would be suppressed, has been dispelled. The police are expressly enjoined not to interfere with persons attending political meetings unless specially ordered, and such orders are not given unless disorder or a breach of the peace is imminent. Public addresses, even in some of the royal parks, are permitted, provided they do not cause any obstruction, and are not of an unlawful character. There are no Government police to watch the delivery of mere political opinion or the tenor of its reception by the auditory. The press is also free from Government interference, through the police, in matters short of crime or not directly incentive to crime.

The sphere of action of the police force in relation to the state has been extended by legislative enactments providing that criminals who have escaped to or from colonies may be followed and removed by process of law, and tried where the crime originated. The practical execution of the law as to these fugitive offenders rests with the police. The same observation applies to the province of police under extradition treaties. But the general action of the police force of a country is bounded by its shores. As the open sea is not the territory of any one nation, it is not competent to any one nation to preserve order or remove all delinquents on its surface, as it is in the ports, rivers, and lakes of a state. When Lord Castlereagh at the congress of Vienna spoke of the "police" to be exercised over ships carrying slaves, Talleyrand asked the precise meaning

of the expression; and, on the English statesman explaining that he intended to refer to what every Government exercised in virtue of its sovereignty or under treaties with other powers, Talleyrand would not admit the existence of any maritime police, except that of each power over its own vessels.

The supervision of the police by the Government stands thus. The commissioner of police of the metropolis of London is appointed by and acts under the immediate direction of the secretary of state for the home department. The commissioner of police of the city of London is in communication with the corporation, who appoint him. There is, however, a power of approval of regulations in the secretary of state. In the counties of England the appointment of the chief constable is by the county magistrates subject to the approval of the secretary of state. In municipal corporations the police, including the chief or head constable, are appointed by the watch committee. In all these cases except in the metropolis the secretary of state leaves the immediate control to local authorities and disclaims responsibility. In Scotland the secretary of state has a voice in the rules for the government, pay, and necessities of the force. The appointment of the chief constable is subject to his approval, but practically there is no interference called for in this respect. In Ireland great authority is vested in the lord lieutenant both with respect to the police of Dublin and the royal Irish constabulary. The immediate government is vested in the heads of the forces, and the parliamentary responsibility is in the chief secretary for Ireland. Reports and returns as to the police forces of Great Britain and Ireland are laid before parliament. The immediate control and responsibility of a cabinet minister for the police of the metropolis of London makes a very important distinction between the position of that force and of the other police forces of the empire. There is, however, a general relationship of the police forces of the country to the state, arising from the contribution (not now limited to a particular proportion) made by parliament to the expenditure for a police force. Under an Act of 1856 the crown appoints three persons as paid inspectors to visit and inquire into the state and efficiency of the police appointed for every county and borough in England and Wales, and to see whether the provisions of the Acts under which they are appointed are duly observed and carried into effect; and upon the secretary of state's certificate of efficiency, laid before parliament, the contribution is made. In the same way an inspector for Scotland reports annually.

It is to be observed that the contribution cannot be made to a borough police not consolidated with the county police where the population is less than 5000. In England the state, except in the city of London, contributes about half the pay of forces which submit to certain regulations, to inspection, and to a definite amount of imperial control. In Scotland the state also contributes. About two-thirds of the cost of the Dublin metropolitan police is met by the treasury. The balance in all the above cases comes from the locality. The royal Irish constabulary is the only force whose ordinary strength is entirely supported by imperial taxation, subject, however, to payment by districts where special services are necessary.

To prevent political influence being brought to bear upon the police, they cannot vote at elections of members of parliament within their district; and the chief officers are disqualified from sitting in parliament.

The relationship of the police forces of the country to the army as a state force is satisfactory. The police is a civil force. Although constables constantly speak of the public as "civilians," the police are in turn styled civilians by soldiers. It is now only on rare occasions that soldiers

Government  
supervision.

Con-  
nexion  
with the  
army.

are required to intervene in the case of riot or tumult, as fortunately the police force is generally sufficient for the preservation of the peace of the country. If disturbance is apprehended in any district, special constables are called upon to aid. It is no less due to the improved temper and habits of the people than to the existence of the police force that military display is rarely needed to suppress riots. In state processions and on some other occasions the police and household troops together maintain the line of route, and where troops assemble for inspection the police sometimes aid in keeping the ground. The police, as constables, are required to carry out the law as to billeting and the impressment of carriages,—at one time a very heavy incident of duty, but considerably lightened by the practice of conveying troops by railway. The police apprehend deserters on reasonable suspicion. Police in charge of a station must receive prisoners, including deserters and absentees subject to military law, if duly sent there by military authority; and, as a person subject to military law is usually left to be dealt with by the ordinary civil tribunal for offences, he is taken by the police before a magistrate. On the other hand no person subject to military law, whether an officer or a private, can neglect or refuse to deliver over to the civil magistrate any officer or soldier accused of an offence punishable in the ordinary mode, or to assist the police in his lawful apprehension; an adjustment of military and civil law is therefore effected.

The duties devolving on a police force require a fuller notice than the general remarks already made.

General  
Duties.

A constable on ordinary patrol duty has to attend to every circumstance that a keen eye and ready ear bring under his notice. In a carefully drawn statute, although not now in general use, the general sphere of observation and duty by constables is thus summarized:—

"During the time they shall be on duty, use their utmost endeavours to prevent any mischief by fire, and also to prevent all robberies, burglaries, and other felonies and misdemeanors, and other outrages, disorders, and breaches of the peace; and to apprehend and secure all felons, rogues, vagabonds, and disorderly persons who shall disturb the public peace, or any party or persons wandering, secreted, or misbehaving himself, herself, or themselves, or whom they shall have reasonable cause to suspect of any evil designs; and to secure and keep in safe custody any such person, in order that he or she may be conveyed as soon as conveniently may be before a justice of the peace, to be examined and dealt with according to law; and it shall and may be lawful to and for the said watchmen, sergeants of the watch, patrols, and other person or persons to call and require any person or persons to aid and assist them in taking such felons, rogues, vagabonds, and all disorderly or suspected persons as aforesaid" (3 & 4 Will. IV. c. 90, § 41).

Relation  
to crime.

Police action in relation to the serious matters constituting crime is familiar knowledge. It is essential to bear in mind that the powers of the police in arresting and otherwise dealing with criminals in a variety of ways is derived from and depends on police constables having been expressly invested with the powers and duties of the old parish constables. Every police force has been given these powers and duties of constables, and the possession of them is so essential that, however they may be supplemented by modern legislation, without them no police force could exist for a day.

A statistical or other inquiry into crime is necessarily beyond the limits of this article. A few facts, however, bear on the efficiency of the police forces.

The returns indicate that the apprehensions in 1881-82 were (omitting fractions) in the proportion of 41 per cent. to the number of crimes committed in England and Wales, against a like proportion in 1880-81, 42 per cent. in 1879-80, 45 in 1878-79, 44 in 1877-78, 46 for 1876-77, and 47 per cent. for 1875-76.

The director of criminal investigations reported for the year 1882 that a comparison of the statistics—which are prepared by an independent service with a scrupulous regard to accuracy—with those of foreign cities shows that the metropolis of London (metropolitan police district), with a territory nearly 700 square miles in extent, covered by more than 700,000 separate houses, and inhabited

by a population barely less than 5,000,000, is the safest capital for life and property in the world.

Although criminal procedure does not admit of being fully treated here as part of the police system, yet as the police by duty as well as practice are in fact prosecutors in the majority of criminal cases, the important part taken by the police force requires notice.

The efficiency of the police, as well as the exigencies of cases, has led to the arrest of offenders or suspected persons in the great majority of felonies and other crimes, where the power exists, without applying to magistrates for warrants in the first instance. Although there are some advantages attendant upon a practice under which magistrates do not hear of the matter until the accused is actually before them, it is undoubtedly better, as recently declared by the commissioners reporting on the criminal code, for the police officer to obtain a warrant where circumstances admit of his doing so. When he arrests, whether with or without a warrant, it is his duty to take the prisoner before a magistrate.

Without attempting to enter fully into the rights and duties of the police in relation to arrest, it may be mentioned that, while the important action of the police is derived from and wholly dependent (except in some cases where recent legislation has found a place) on the older powers, science has been made subservient in facilitating the application of these powers to police duties. As in old times the reasonable suspicion giving the right to arrest may still be founded on personal observation and information in the ordinary mode; but the electric telegraph and the photograph now lend their aid as recognized agents in favour of justice and truth far more than in aid of fraud and deception.

If an arrest is without a warrant, it is the officer's duty to show that he acted rightly by establishing at least that he proceeded on reasonable information. His task is generally much more. He or some police officer, whether acting under a warrant or not, has to adduce all the evidence to justify a commitment for trial, or, if the case is one in which the court of summary jurisdiction has the power, for a conviction. In carrying out this duty even in simple cases a multitude of matters have to be attended to in which a number of police officers take a part. Whether the arrest is made by a constable on his beat or under other circumstances, the ordinary duty involves taking the prisoner to the police station, where the charge is entered. He is then taken before the magistrate, or, in some cases, bailed. If the charge be one of felony it generally involves a remand, not only for the attendance of witnesses, but to ascertain the prisoner's antecedents; and these remands are often multiplied in complicated cases. Every remand involves the conveyance of the prisoner to and from the prison or "lock-up,"—generally the former. Detective police attend at the prison to ascertain whether the accused has been previously convicted or charged. Witnesses must be seen and their attendance secured. If the prisoner is eventually committed for trial it is the duty of the inspector or other officer having charge of the case to aid the magistrate's clerk in making out the certificate of costs, so that the proper amounts for the allowance of witnesses are inserted. Although in ordinary cases there is a nominal "prosecutor" (the person who has been wounded or lost his property), if he enters into a recognizance before the magistrate, he leaves everything to the police, who have to inform him even when and where he must attend for the trial, and the police are required in many cases to give the necessary instructions for the indictment; and, when the proper time arrives for the trial at the sessions or assizes (of which public notice is given), the police must inform the witnesses and arrange for their conveyance and prompt attendance in the precincts of the court, first before the grand jury, afterwards on the trial. A police officer must attend the taxing officer, give the necessary particulars as to the witnesses, and see that they receive their allowances.

The responsibilities and duties of the police may be varied, but on the whole are scarcely diminished, if there is a solicitor for a private or for the public prosecutor; the Act of 1884 relating to the public prosecutor regards the police as essential parties, and it is certain that no general system of prosecution can be carried on with diminished police intervention.

The duties of police to accused persons are too important to be passed over in complete silence. To say that they involve perfect fairness ought to be a sufficient guide, but it is right to add that the indirect as well as the direct extortion of statements, either by threat or promise, is forbidden. On the other hand to caution accused persons is not the province of the police; as on the one hand a police officer ought not in general to put questions, so on the other hand he ought not to prevent voluntary statements. His general duty is to listen, and to remember accurately what the accused says. It is often the duty of an officer to give information to the accused, as for instance of the nature of the charge on which he is arrested or to read the warrant; but information of this kind should not be given interrogatively. It sometimes happens,

however, that in the course of inquiries a person makes a criminatory statement to a police officer, in consequence of which it is the duty of the officer to arrest him. This is distinct from questioning a person whom the officer has not merely suspected but predetermined to arrest.

Some other duties, the growth of modern times and unknown until recently, devolve on the police in relation to criminals. They arise from the release of offenders sentenced to penal servitude before the expiration of the period, on certain conditions, or of offenders sentenced, after the expiration of their sentence of imprisonment, to be under police supervision for a given period. Both classes of convicts involve the performance by the police of very responsible duties in reference to reporting and giving notice of changes of residence, so as to make the watch and supervision a real thing, and at the same time to give the convicts the opportunity, as intended, of gaining an honest livelihood at some labour or calling. It is a frequent source of complaint by the convicts that they are so watched that they cannot obtain employment, and are driven into the repetition of crime.—the police retorting that the allegations are untrue, and that the fresh offence is the result of the habitual offender's incurable love for crime. Any constable in any police district may, if authorized so to do (in writing) by the chief officer of police of that district, without warrant, take into custody any convict who is the holder of a licence if it appears to such constable that such convict is getting his livelihood by dishonest means, and may bring him before a court of summary jurisdiction. The system of "reporting" is itself a branch of police administration of great importance, and requiring considerable knowledge. Its headquarters may be said to be in the metropolis and under the supervision of the police of that district, but it involves constant communication with other districts and observation throughout the kingdom.

The extent of police duty in respect of such offenders is shown by the fact that, according to the last published return, there were in England and Wales 1265 convicts on licence and persons under sentence of supervision.

**Relation to reformatory.** The police are in general the instruments for carrying out the statutory provisions respecting certified industrial schools and reformatories. Not only is the process for the most part directed to the police, but magistrates and others interested look to the force for suggestions and assistance. In some respects it would be desirable if industrial schools, as distinguished from reformatories, could be worked without the intervention of police agency, but it seems impracticable.

**Execution of process.** An important police function relates to the execution of process, and is not confined to subjects or cases in which the force is collectively or individually concerned in the performance of their duty. Whether the process is a warrant or a summons, its execution or service is in the hands of the police. Magisterial warrants of apprehension and search are by law, in other than exceptional cases, necessarily directed to the police as peace officers, whether their purpose be to bring the person before the tribunal or to convey him from it or from one place to another; and in other warrants of execution, although parochial officers are often joined, police are also included to prevent abuses of the law to which the poor are so much exposed. Police officers are now expressly required to have the direction of warrants of distress. The service of a magisterial summons, although not in general prescribed to be effected by a police officer, in practice properly devolves on the force. In the metropolitan police district all police service must be by its officers. In a great variety of matters where notice has to be given to persons, the duty of communicating it either verbally or in writing or in print is thrown on the police. So convenient a medium for the orderly administration of purely civil matters are the police found that, at the request of the local government board, the police are allowed to deliver and collect voting papers in the election of parochial officers.

The increased area over which a police constable as compared with the old parish constable has jurisdiction facilitates both arrests and service of process. Although stationed within a defined area of limited jurisdiction, the duties of the force often involve the operation of functions without geographical limits, requiring the actual presence of its members outside as well as the performance within the district of much that relates to the exterior.

The service of process calls for constant communication between different police forces. The law provides for the backing of warrants, by which a constable can act beyond his ordinary jurisdiction or by which the warrants can be transmitted. A magisterial summons for appearance does not require formal transmission. It is addressed not to the police but to the defendant, and can be served by an officer of any district; but, as until recently the proof of service could only be given by the personal attendance of the serving officer at the magistrate's court, great expense was incurred in travelling to effect service, and inconvenience in attending to prove it. This has been remedied in most cases by allowing service to be proved by a declaration before a magistrate.

The transmission of process, declarations of service, payment of

fees, and many other incidents arising in apparently the most simple cases now involve constant communication between police forces by whatever distance they may be separated.

A few lines must suffice on the general duties of the police force in Miscellaneous relation to a variety of other matters. Some of these are closely connected with crime, others with municipal regulations only. The duties, police, as having all the duties of constables, act as coroner's officers; they make minute inquiries as to suicides, accidents of every kind, insane persons and their apprehension, and deal with destitute persons and persons seized with sudden illness in the streets, and with vagrants.

In populous districts the adjustment of street traffic, of securing Street the comfort as well as safety of persons in passing to and fro, traffic, whether on foot or otherwise, forms a very important branch of the constable's duty. This may be and often is effected by the mere presence of the constable passing on his round without greater exercise of his authority than a request to persons to move or to wait at crossings. Unless in crowded parts, this highway branch of duty may consist in preventing riding and driving furiously, or on footpaths. The general or local laws of each district give ample scope for the exercise of the police constable's authority and the performance of his duties in such matters, including obstructions of all kinds.

In the metropolitan police district the commissioner has large powers, including the power to prescribe special limits in the metropolis within which some acts affecting the general ease and freedom of the public are forbidden which are innocent elsewhere.

On the police almost invariably devolve the licensing of public carriages and the enforcement of the great variety of regulations respecting them. In the metropolitan police district the licensing of public carriages is vested in the secretary of state, who makes numerous regulations respecting the carriages and their drivers and proprietors, and gives (under power vested in him by the legislature for that purpose) the administration of this important branch of the law to the commissioner of police. Elsewhere in England and Wales the administration of the law in relation to hackney carriages is in the hands of local authorities. The police have charge of the maintenance of good order in houses and places licensed for the licensed sale of intoxicating liquors, including inquiries and notice as to premises, all kinds of licences, renewals, and transfers, and of course involving the conduct of numerous persons, not only of the licensed persons and those in their service, but of persons frequenting their houses, not excepting the members of the police force.

The laws and regulations for common lodging-houses in the Regulated metropolis are under the police. Other traders exercise their trades, constant vigilance, including pawnbrokers, marine-store dealers, pedlars, and chimney-sweepers.

Among almost an infinity of offences may be enumerated those involving cruelty to animals, prize fights so called, and all descriptions of unlawful brawls (including brawling in places of public worship), gaming, gambling, and betting, lotteries, disorderly houses, dangerous performances, the infraction of fence months and seasons for birds and fish, the fraudulent removal of goods, violations of cattle plague orders (which the police are expressly required to observe and enforce, involving of late years most arduous duties), and the sale of unwholesome food and of poisons. The police have also to deal with the care and keeping of explosive substances, animals straying, and dogs reasonably suspected to be mad or not under proper care.

Some public offences, such as the use of inaccurate weights, adulteration of articles of food, &c., are generally dealt with by inspectors and other special officers, although it is undoubtedly the duty of the police to aid in enforcing the law, and to report to the proper quarter offences coming to their knowledge. In the metropolis, smoke nuisances are dealt with as police offences.

The police aid the inland revenue in a variety of ways, and, Dog-tax, although it is generally undesirable for the police to take part in the collection or enforcement of taxation, they are required in the metropolitan district, by order of the secretary of state, to enforce as far as lies in their power the payment of the dog tax, their other duties giving them greater knowledge on the subject.

In visiting places of amusement the police are often performing Places of duties of a multifarious character. In general the one object is the amusement-maintenance of good order, but sometimes the observation extends next to the character of the amusement and the infringement of licences.

Apart from the special duties as to the restoration of property Lost property, for which there are special provisions, the police exercise a reasonable rather than a specially assigned duty in facilitating the recovery of lost and stray property by the rightful owners.

A very few words must suffice for notice of a subject which has Prostitution been a vexed question before as well as since the establishment of tates. a police force in the country, and down to the present moment—the action of police powers as to street prostitutes. Practically this action has nearly the same limits throughout England and Wales. In the metropolitan police district and in the City of London it is an offence for a common prostitute or night-walker to

loiter or to be in a public place for the purpose of prostitution or solicitation to the annoyance of the inhabitants or passengers. Elsewhere the offence is in much the same terms included in the Police of Towns' Clauses' Act, 1847, and is so applied to all urban authorities under the Public Health Act, 1875. In the practical application of the law it is generally considered that there must be some evidence of a personal annoyance by and to one or more persons to justify a conviction.

The preceding survey of some of the multifarious functions of a police force affords an illustration of Bentham's classification of the business of police into distinct branches:—police for the prevention of offences; police for the prevention of calamities; police for the prevention of endemic diseases; police of charity; police of interior communications; police of public amusements; police for recent intelligence and information. No attempt, however, is made in the present article to follow such classification. It would lead the reader astray, where the object is to treat principally of the police force.

Area of  
action.

As to the defined area of police action, for general purposes the legal rights and powers of a police force (subject to the observations already made) are coextensive with the police district. In the metropolitan police district the members of the force have the powers of constables in the adjoining counties (10 Geo. IV. c. 44, § 4; 2 & 3 Vict. c. 47, § 5).

The determination of the geographical area of a police district is necessarily governed by a variety of circumstances. Physical features have sometimes to be taken into account as affecting the demarcations of intercourse, more frequently the occupations of the people and the amount of the population. A district may be too confined or too large for police purposes. The limited ideas of simple-minded rustics of a former generation whose views of complete independence consisted in inhabiting two adjacent rooms in different parishes, so as to effectually baffle the visits of parochial officers, is probably a notion of the past; but obstructions of a like kind may arise from too narrow boundaries. On the other hand dense populations or long-accustomed limits may outweigh convenience arising from a wide area.

In any case the making of altogether new boundaries merely for police purposes is very undesirable. The county, or divisions of a county or city, or the combination of parishes, ought to be and are sufficient for determining the boundaries of a police district. A boundary, moreover, that does not admit of ready application for rating is impracticable.

In England, Wales, and Scotland, with the exception of the metropolitan police district and the area of the City of London (geographically included within but distinct from it in police government), the police districts are for the most part identical in area with the counties. Large towns have police forces distinct from the county force surrounding them. There are 290 police forces in the island,—a number liable to frequent variation, as separate forces are created or existing forces are combined, for which powers exist.

Strength of police force. By far the largest and most important force, as regards the character of both area and numbers, is that of the metropolitan police district, comprising 20 divisions. The total number of the police (including of course the county constabulary) for England and Wales for the year ending 29th September 1883 was 34,488, an increase on the previous year of 1315. During the last decade the increase in the total number of the police, allowing for the augmented population, is trifling.

The following are the numbers composing the different forces in 1882-83 :—

In boroughs under the Municipal Corporation Act and under local Acts.....	9,685
In counties .....	11,255
Metropolitan police constables, including royal dockyards..	12,663
City of London .....	885
Total.....	34,488

The total gives one constable for every 774 of the population, according to the census of 1881. In boroughs, &c., there is 1 for

every 758; in counties 1 for 1231; in the metropolitan police district (deducting 807, the number employed in royal dockyards, and 446 paid for by public companies and private individuals) 1 for every 413; and in the City of London 1 for every 57 of the City population, as enumerated on the night of the census of 1881. The total number, exclusive of the commissioner and assistant commissioners, belonging to the metropolitan police force on the 1st January 1884 was 12,404,—comprising 10,741 constables, 1028 sergeants, 608 inspectors, 24 divisional superintendents, 1 chief superintendent (of the criminal investigation department), and 2 district superintendents.

The strength of the police force in proportion to population varies considerably in each county of Scotland, ranging for the year ended 15th March 1884 from 1 in 731 in Selkirk to 1 in 2438 in Banff. In burghs it varies from 1 in 532 in Edinburgh and 1 in 535 in Glasgow to only 1 in upwards of 1500 of the population in the smallest burghs.

The strength of the royal Irish constabulary on the 1st July 1882, the geographical area of which comprises all Ireland, consisted of 258 officers and 13,750 men, and it was subsequently increased to 14,601 of all ranks.

The equal distribution of the force throughout a district—Distribution. not a uniform distribution either as to area or population, but equal in accordance with wants—is one of the greatest difficulties in the administration of a police force. It is not merely that recruits must be sought for to keep pace with increase or variations of population, but daily and hourly events necessitate daily and hourly changes of distribution. The duty is not merely to draw off men from adjacent divisions to the spot for a few hours, where they can be best spared, but to fill places where required. It must be remembered that extra work by day incapacitates men for the night watch, and it takes days to restore the equilibrium. It is needless to say that, although the services of the police force may not be required to aid in the extinction of a fire, their presence is required in great numbers to preserve order; and thus men are necessarily kept on duty beyond their prescribed hours. Nor, in many of these cases, whether foreseen or unforeseen, is the distribution of the force self-adjusting. Let all do what they may in aid through all ranks of the force, inequalities must occur; and before the gaps are made up a fresh displacement occurs. Much may be done and is done by a system of reserves, and by averaging the yearly extra calls on the time of a force; but after all there is no perfect equality. The peacefully slumbering citizen may be startled by the announcement that, although the force of the metropolitan police district has been under anxious management for upwards of half a century, on no two nights since its formation have the beats been patrolled to precisely the same extent.

The police system of necessity involves the existence in Stations. a district of police stations or lock-ups, for the temporary detention of prisoners; and magistrates have generally the power to remand prisoners to these for short periods. Power to make police stations occasional courts of summary jurisdiction has been recently conferred on county magistrates. A police power of admitting arrested persons to bail in petty cases, with a corresponding duty to exercise the power, is vested in the police in authority at stations. This power has existed throughout the metropolitan police district from the first establishment of the police on its present footing, and also in the City of London and in many populous places under local Acts; and the principle has been recently extended to the country.

The selection of persons for the force is a matter subject to general as well as special regulations, varying in each district according to circumstances of place and time. Testimonials as to character and antecedents should be and are in practice always required. For health a medical examination is enforced; as to general education, reading and writing are usually required; special education for police duties is necessarily unattainable before entry, but in the metropolitan police force of England approved

Qualifications for service.

candidates are admitted on probation, and drilled. When finally approved of, on admission to the force they make a declaration, as already stated, to duly serve.

**Discipline.** Discipline is enforced by dismissal, reprimand, fines, removal to another division, or degradation in rank. Violation or neglect of duty may be punished by summary conviction.

**Detectives.** For the detection of crime and offences it is obviously necessary that some members of the force should perform their duties out of uniform. Some are constantly employed as detectives, others doff their official dress on emergencies. In the English metropolis the detective officers form a distinct branch of the police service, called the criminal investigation department. One of the assistant commissioners of the metropolitan police attends specially to this department, to which a chief superintendent and a separate staff of inspectors and sergeants are attached, having an office in Scotland Yard, with officers of the department placed in the divisions of the district. The qualifications of the principal officers are special, and they are selected for their aptitude, knowledge of foreign languages, and a variety of circumstances rendering the application of the ordinary routine of training undesirable and impracticable. Constables and sergeants of the department are selected from the general body of the force. Officers of the detective department of the metropolis in the performance of their various duties travel all over the globe, to foreign states as well as to the colonies. The number of detective officers in England and Wales for 1882-83 was 551.

**Chief officers.** The chiefs of the metropolitan police force are the commissioner and three assistant commissioners, one acting in place of a director of criminal investigations, who has recently retired. A legal adviser to the commissioners is appointed by the secretary of state. Besides the divisional superintendents, there are now two district superintendents, who visit the whole of the divisions. All promotions in the service up to the rank of superintendent are made from the next rank below. When vacancies occur the rule is to recommend to the commissioner those best qualified in all respects, seniority of service being duly considered; but an educational examination by the civil service commissioners is requisite. A different standard and subject of examination is provided for each rank:—  
(1) constables for sergeants; (2) sergeants for inspectors; (3) inspectors for superintendents.

**Orders.** Orders having the approval of the secretary of state for the government of the police of the metropolis in a variety of matters are printed and issued daily throughout the district. The majority of these orders relate to incidents and contingencies of the passing hour, and affect particular divisions: others are of a permanent character and require attention throughout the district. Such orders form the practice of the police in almost all matters of detail either not specifically regulated by Act of Parliament or requiring explanation and elucidation; and, if they are carefully considered and prepared, their issue must produce a uniform code of police procedure for the force.

**Maintenance.** The cost of a police system is defrayed from a fund formed by local rates or by imperial funds, or both, and in part by the appropriation of fines and the fees payable by law in respect of the performance of individual duties, but not permitted to be retained by the performer. This fund is collected and expended through the medium of a receiver, treasurer, or other officer, and a staff of clerks, with the aid of the superintendents, inspectors, and police officers. The regulation and amount of the salaries (which are generally paid weekly or monthly according to the class), depend of course on local and other circumstances, but do not vary frequently. Where agriculture is the

general occupation the pay of members of the force is low. Where mining and manufactures compete with agriculture it is higher; where they are the principal business they create a demand for labour which raises the salary of the constable as well as those of other workers. The pay of the constables of the metropolitan district varies from £62, 11s. 6d. to £83, 8s. 7d. per annum, that of the sergeants from £88, 12s. 11d. to £146, of the inspectors from £88, 12s. 11d. to £351, 19s. 4d. The metropolitan police constable is subject to deductions for pension, and he contributes on the average about 2d. a week to gratuities for the widows or orphans of comrades who have recently died, and is under a rent of about 3s. 6d. if single and living out of the section house, and about 6s. 6d. a week if married. Analogous conditions exist in all the great city forces. The Liverpool constable begins with 26s. 8d. a week; 8d. a week is deducted at first, and 10d. after a short period, towards pension fund; an average of 4s. a week is spent on the lodgings of a single, and from 5s. 6d. to 7s. 6d. on those of a married man. Model scales of pay which were suggested by the secretary of state in 1879 have been adopted by several county forces in Scotland, but not in burghs.

In addition to fixed salaries, the police system generally provides for rewards for extraordinary diligence and gratuities out of the police fund. Gifts or payments to individual officers by private persons ought to be controlled in a well-regulated system, where good conduct and vigilance ought to be closely watched to ensure promotion in due time. Specially meritorious acts, however, are sometimes admitted for pecuniary recognition by magistrates, or representative bodies. In England the police are not now permitted to participate in Government or other rewards for the discovery of crime. Provision is almost invariably made for pensions by a fund formed by a scale of deductions from pay, as already stated, and to some extent by fines. The general subject of superannuation is, however, too large to be entered upon here. For the ordinary services of the police within their local jurisdiction no charge should fall on particular persons who happen to derive special advantage from such police duty. It is a general benefit for which in one form or another the inhabitants are taxed.

Other incidental expenditure in the performance of duties is met in various ways. The heavy cost connected with the conveyance of prisoners to and from prison on committal and remand is in England, except in Middlesex, borne by the state, being paid by the prison commissioners. The preliminary cost attending the arrest in the first instance is generally borne by the police fund. In some exceptional cases where the police perform special duties beyond their district, the cost is thrown on individuals putting the law in motion. Thus the costs incurred under extradition treaties and under the Fugitive Offenders' Act in following criminals and bringing them back within the jurisdiction for trial where the offence was committed or arose are not expressly provided for by statute; but the regulations laid down by the secretary of state require all costs to be paid by applicants in the case of fugitive offenders.

The police have special powers in furtherance of their duties; even the exemption from toll (not now of general value) has that aspect. They are not only exempted but disqualified from various local offices as interfering with the time and attention required for the full performance of their duties. Rules of the service generally forbid constables following any trade or occupation of profit even when not on actual duty, and in the metropolitan police district of London this disqualification extends in practice to their wives. The police are protected in the discharge of

their duties in a variety of ways. Assaulting, resisting, or wilfully obstructing a peace officer in the due execution of his duty or any person acting in aid of such officer, and assaults with intent to resist or prevent lawful apprehension or detainer, are punishable summarily as well as upon indictment. Refusing to assist a constable in the execution of his duty in order to preserve the peace is an indictable misdemeanour at common law. The law specially provides for offences by the police in stealing or embezzling property entrusted to them in virtue of their employment (24 & 25 Vict. c. 96, §§ 69, 70).

**Uniform.** Wearing a distinctive dress or uniform in the general performance of duty is a matter of the highest importance. It commands and has a very great effect in producing obedience and conformity to law and order, and in preventing violence, without the use of even a word or threat; and it has a scarcely less important effect in protecting the public from the illegal or irregular action of the police when on duty, when the dress involves, as it ordinarily does, the exhibition on its exterior of a letter and number.

**Arms.** The extent to which the individual members of a police force are allowed or required to be armed when on duty for the enforcement of the law or for their own protection from violence is a matter of important discretion; for, although the principles of law, entailing or withholding the right of peace officers or private persons to employ weapons of offence, are comparatively well-defined, the emergency depends on a variety of circumstances on which it is extremely difficult for heads of forces to make regulations for the guidance of the men. In general the only weapon carried about the person of a police constable is the familiar wooden staff of office of the peace officer, and that not in the hands openly, but in a sheath at his side and only drawn when required.

**Yearly cost.** The cost of the police in England and Wales for the year ending 29th September 1883, including salaries and pay, allowances, clothing and accoutrements, horses, harness, forage, buildings, station-house charges, printing, stationery, and other miscellaneous charges was £3,367,678, a net increase of £107,598 as compared with the previous year. The cost of the separate forces for the year and the amounts contributed from the public revenue stand thus:—

	Total Charge.	Contributed from Public Revenue.
Borough police.....	£857,863	£379,210
County.....	1,101,621	435,133
Metropolitan police (including naval dockyards and military stations).....	1,317,303	508,183
City of London.....	90,891	...
Total.....	£3,367,678	£1,322,526

Deducting the City of London police, towards which no contribution is paid from the public revenue, the proportion of the amount so contributed was 39·5. But if the total charge for the metropolitan police is reduced by £131,560 received from public departments for special services rendered by the police, the proportion contributed from the public revenue, computed upon £1,185,743, was 42·8 per cent. All moneys received for the service of the metropolitan police between 1st April 1883 and the 31st March 1884 amounted to £1,469,930, 4s. 5d. Of this total the sum of £639,751, 7s. 4d. was derived from the metropolitan police rate, and £510,933 as the contribution from moneys voted by parliament of 4d. per £1 upon £30,663,903, the assessed rental of property in the metropolitan police district. The pay, clothing, and equip-

ments of the force from constables to superintendents was £1,024,587, 13s. 9d.

In concluding this general account of the existing police system, it is well to mention that the old system of parish constables no longer exists as a general institution. As an auxiliary force, although not forming part of the establishment of a police system, special constables form an important resource in the preservation of the peace (see CONSTABLE).

*History of the Introduction of the British Police System.* History of British police system.—It is a self-evident proposition that the duties of watch and ward, whether under the Statute of Winchester or otherwise (see CONSTABLE), demanded greater attention in populous places than in scattered hamlets. Nevertheless the inefficiency of the arrangements was notorious from an early period, and is well illustrated by the "charge" of a Dogberry and the graver complaints of Lord Burleigh of the dulness of constables. In relation to London alone its state down to 1828 forms a subject not without general interest (see LONDON). Here it must suffice to say that committees of the House of Commons in 1772, 1793, 1812, 1817, 1818, and 1822 produced facts tending to the formation, but with hesitation, of a police establishment. To Dr Colquhoun, a magistrate, the chief merit is due of having, before the close of the 18th century, in a treatise *On the Police of the Metropolis*, drawn attention to the subject. He pointed out that police in England may be considered as a new science, the properties of which consist, not in the judicial powers which lead to punishment, and which belong to magistrates alone, but in the prevention and detection of crimes, and in those other functions which relate to internal regulations for the well-ordering and comfort of civil society. His work went through several editions in a very brief period. It was not, however, until 1828 that a committee of the House of Commons, appointed at the instance of Mr (afterwards Sir Robert) Peel, the home secretary, to inquire into the cause of the increase in the number of commitments and convictions in London and Middlesex, and into the state of the police of the metropolis and of the districts adjoining, reported that a decisive change should be made, and an efficient system of police instituted for the adequate protection of property, and for the prevention and detection of crime in the metropolis. In the following year the famous Act for improving the police in and near the metropolis was passed (10 Geo. IV. c. 44).

The Act constituted a police district, excluding the City of London, with a radius of 12 miles. Two persons were constituted justices of the peace (afterwards called commissioners of police) to administer the Act under the immediate direction of a secretary of state, and having a police office in Westminster. This office, established in a room with a table and two chairs, in an outlet from Whitehall, is the origin (as regards police associations) of the far-famed "Scotland Yard," with its now enlarged staff, but still inadequate structural arrangements. A sufficient number of "able men" (at first about 3000) constituted the force to whom were given, when sworn in, the common law powers, privileges, and duties of constables for preserving the peace and preventing robberies and other felonies, and apprehending offenders against the peace, with the duty to obey the lawful commands of the commissioners. The district was formed into divisions and sections, and ranks established on the same general system as at present exists. A fund was created principally by rates on the district for the maintenance of the force, with rewards for extraordinary diligence and compensation for injuries.

As might have been anticipated, the introduction of the new system of police attracted great public attention. At

this distance of time, with the experience of an intervening half century, it is difficult to believe that the change by which the police system became in a few years as much a necessity of towns as their public lighting (and lighting and watching were of much the same age and character, and were frequently coupled in legislation) was regarded otherwise than with the approval of well-regulated minds. It substituted the vigorous action of a really responsible and well-regulated body, acting in an enlarged area, and independently of parochial authorities, for the partial and lax action of a variety of ill-governed and inadequate bodies. Legitimate but passing regrets might be natural as the introduction of vicarious action superseded the necessity for self help and responsibility. No poet could thereafter compose, as a sally of fancy, the adventures of a London citizen between Cheapside and Edmonton mounted on a runaway horse with associated gentlemen galloping after a presumed horsestealer. To arrest the horse, whether a runaway or stolen, only a blue-coated policeman would thenceforward be seen on the track. The objections raised to the new police were of a more serious although scarcely of a more substantial kind. The assumption that a good police could only be attained at the expense of liberty, and that it necessarily involved some arbitrary principle opposed to the free constitution of the country, had been countenanced even by the report of the committee of 1822, in which it was remarked that it was difficult to reconcile an effective system of police with that perfect freedom of action and exemption from interference which are the great privileges and blessings of society in the country. With such sedate misgivings, it is not to be wondered at, when the system was actually introduced a few years later, that cries arose in the streets of "down with the new police," and that the constables were frequently followed by hooting crowds calling them obnoxious names. By associating them with the statesman who introduced the measure, and calling them "Peelers" and "Bobbies," names perpetuated to the present day and apparently likely to last, a compliment was really paid to the minister and to the force. But at that time Peel was attacked in parliament and suspicion thrown on the Act because the same minister had introduced Roman Catholic emancipation.

Within four years of the establishment of the police force the hostility seems to have culminated. It was evinced by the result of a collision between the police and a meeting of Chartists in Coldbath Fields in May 1833, in which three police officers were stabbed and one killed with a dagger. At the inquest the coroner's jury returned a verdict of "justifiable homicide," in the teeth of the evidence. The crown thereupon adopted the strong but justifiable course of applying to the Court of King's Bench, and the inquisition was quashed. Committees were appointed by the House of Commons to inquire into the circumstances of the meeting, and also regarding an allegation of inhabitants of the Surrey side that policemen were employed as spies, and a third committee was appointed to inquire into the state of the police and crime in the district. The police system and the force as a whole came out with credit, notwithstanding individual instances of undue exercise of power calling for greater control.

There was no hesitation as to the duty of maintaining the principle of the new system, and the popular hostility gradually died away. After intermediate parliamentary reports and legislation by way of extension, an important Act was passed in 1839, reciting that the system of police established had been found very efficient and might be yet further improved (2 & 3 Vict. c. 47). The metropolitan police district was extended to 15 miles from Charing Cross. The whole of the River Thames (which had been

in its course through London, so far as related to police matters, managed under distinct Acts) was brought within it, and the collateral but not exclusive powers of the metropolitan police were extended to the royal palaces and 10 miles around, and to the counties adjacent to the district. Various summary powers for dealing with street and other offences were conferred.

At the same time that the police were put on a more complete footing and the area enlarged, provision was made for the more effectual administration of justice by the magistrates of the metropolis (2 & 3 Vict. c. 71). The changes that occurred in magisterial functions are scarcely less remarkable than the transition from the parish constable to the organized police. The misdirected activity of the civil magistrate in the 17th century is illustrated by the familiar literature of Butler, Bunyan, and others. The zeal of that age was succeeded by apathetic reaction, and it became necessary in the metropolis to secure the services of paid justices. The malpractices of the so-called "trading justices" of the 18th century are described and exposed for all time by Fielding, who honourably performed the duties of justice of the peace for Middlesex and Westminster. At the beginning of the 19th century outside of the City of London (where magisterial duties were, as now, performed by the lord mayor and aldermen) there were various public offices besides the Bow Street and the Thames police offices, where magistrates attended. To the Bow Street office was subsequently attached the "horse patrol," and each of the police offices had a fixed number of constables attached to it, and the Thames police had an establishment of constables and surveyors. The horse patrol was in 1836, as previously intended, placed under the new police. It became desirable that the horse patrol and constables allotted to the several police offices not interfered with by the Act of 1828 should be incorporated with the metropolitan police force. This was effected, and thus magisterial functions were completely separated from the duties of the executive police; for, although the jurisdiction of the two justices, afterwards called commissioners, as magistrates extended to ordinary duties (except at courts of general or quarter sessions), from the first they did not take any part in the examination or committal for trial of persons charged with offences. No persons were brought before them. Their functions were in practice confined to the discipline of the force and the prevention and detection of offences, by having persons arrested or summoned to be dealt with by the ordinary magistrates whose courts were not interfered with.

Important alterations have been made since 1839 in the arrangements affecting the metropolitan police. In 1856 one commissioner and two assistant commissioners were substituted for two commissioners, and a third assistant commissioner has now (1884) been added. In 1866 jurisdiction was given to the metropolitan police in the royal naval dock yards and principal military stations of the war department in England and Wales, and within 15 miles, with the restriction that the powers and privileges of the constables of the metropolitan police when without the yards, naval and marine hospitals and infirmaries, and marine barracks or stations, and not on board or in any ship, vessel, or boat belonging to the queen or in her service, shall only be used in respect of the property of the crown or of persons subject to naval or marine or military discipline (23 & 24 Vict. c. 135).

Under this Act the metropolitan police exercise jurisdiction and perform duties extending from Chatham on the east and Dover and Portsmouth on the south to Devonport, Portsmouth, and Pembroke on the west, and of course including Aldershot. The expenses incurred are defrayed by parliament.

Connected with the last-mentioned Act, and in consequence of it, has been the exercise for eighteen years by the metropolitan police of the powers of the Contagious Diseases Act, 1866, and the medical examination of women under it,—a much debated and warmly contested power. The refusal in 1883 by the House of Commons to provide money for the expenses of the Act led to the discontinuance of action by the metropolitan police under it.

The Metropolitan Streets Act, 1867, for regulating the traffic in the metropolis, and for making provision for the greater security of persons passing through the streets and for other purposes, gives great discretionary power to the commissioner of police whether of the metropolis or of the City of London, in relation to prescribing special limits, with the approval of a secretary of state, within which regulations to prevent obstructions in the streets (without interfering with other powers) may be made and enforced. Apart from the special limits, general regulations are prescribed as to hackney carriages, stray dogs, and various other matters.

As already observed, the Acts noticed as to the metropolitan police district did not apply to the City of London, which was and is left as an island surrounded by the metropolis. The nightly watch and "bedels" within the City were regulated, and rates imposed for the purpose, in the reign of George II. In 1839, on the same day that the Act of Parliament passed with respect to the metropolitan police, a corresponding Act was passed for the City of London and a salaried commissioner of the police for the City and its liberties appointed by the common council. The power to make regulations relative to the general government of the police is vested in the commissioner, subject to the approbation of the mayor and aldermen and a secretary of state. In case of emergency the secretary of state may, at the request of the lord mayor, authorize the metropolitan police to act within the City of London under the command of their own officers, and on the other hand the lord mayor may, at the request of the secretary of state, in the like emergency, authorize the City police to act under their own officers within the metropolitan police district. The Act gives various special powers as to offences corresponding with the Metropolitan Police Act of 1839. It provides for a police rate, and the corporation is required to pay out of its revenues a fourth part of the expenses of the police force. No rated person is liable to any watch or ward by virtue of the Statute of Winchester (13 Edw. I.), and the ancient custom of electing ward constables is suspended.

In the article LONDON (vol. xiii. p. 834) some statistics are given as to the police courts of the metropolis, and the state of crime and the proportion of police to the population under the last census.

In considering the introduction of the police system into the rest of England, it is to be borne in mind that in many towns and places an organized system of watching by paid officers, whether constables, watchmen, or police, was established by local Acts of Parliament, at various dates, but especially in the early part of the present century.

An attempt at a paid county force was made in 1829 (in the same year with the Metropolitan Police Act), but not on corresponding lines, by a local Act to enable the magistrates of the county palatine of Chester to appoint special high constables and assistant petty constables (10 Geo. IV. c. 97). In 1830, and again three years later, provision was made to facilitate voluntary lighting and watching parishes throughout England and Wales. In 1835 the regulation of municipal corporations included power (since renewed) to appoint, by a watch committee, constables called "watchmen" paid by a watch rate.

Great facilities having been given by the legislature for the appointment of special constables (an auxiliary elsewhere noticed), provision was made in 1839 for the appointment of county paid constables where the ordinary officers for preserving the peace were insufficient for that purpose and for the protection of the inhabitants and for the security of property within the county. The number recommended (not exceeding one man for every thousand of the inhabitants, after deducting corporate boroughs already provided for, a restriction in after years removed from the statute book) and the rates of payment were required to be reported to the secretary of state, who made and laid before parliament rules for the government, pay, clothing, accoutrements, and necessities of such constables; and thereupon the justices appointed, subject to the approval of the secretary of state, a chief constable, who had the appointment, control, and disposition (subject to the approval of the justices) of the other constables, and a deputy and superintendent to be at the head of the constables in each division of the county. On these constables were conferred all the powers and duties of constables by the common law or statute.

At first the salaries and allowances and expenses of the Act were paid out of the county rate (2 & 3 Vict. c. 93), but in the following year (1840) the Act was amended and extended, and a separate police rate levied in the county. Provision was at the same time made for a superannuation fund and for "station houses and strong rooms," and for consolidating the police of a borough with the county; and on the other hand, as the number of constables needed may be different in different parts of the same county, it might be divided into police districts, each district paying for its own constables. Power is given to the chief constable to appoint (with the approval of the justices) additional constables at the cost of individuals, but subject to the orders of the chief constable.

In 1842 an important statute was passed enacting that for the future no appointment of a petty constable, head-borough, borsholder, tithing man, or peace officer of the like description should be made for any parish at any court leet, except for purposes unconnected with the preservation of the peace, and providing, as a means of increasing the security of persons and property, for the appointment by justices of the peace in divisional petty sessions of fit persons or their substitutes to act as constables in the several parishes of England, and giving vestries an optional power of providing paid constables. The justices in quarter sessions were empowered to provide lock-up houses for the confinement of persons taken into custody by any constable and not yet committed for trial, or in execution of any sentence, or instead to appropriate for that purpose existing lock-up houses, strong rooms, or cages belonging to any parish (5 & 6 Vict. c. 109). Constables appointed under this Act were made subject to the authority of the chief constable or superintendent, if any, appointed under the Act of 1839.

Under the Acts of 1839 and 1840 the establishment of a paid county police force was optional with the justices. After a further interval of fifteen years it was found expedient, for the more effectual prevention and detection of crime, suppression of vagrancy, and maintenance of good order, that further provision should be made for securing an efficient police force throughout England and Wales, and the previous optional power became compulsory (the Police Act, 1856). In every county in which a constabulary had not been already established under the previous Acts for the whole of the county, the justices in quarter sessions were required to proceed to establish a sufficient police force for the whole of the county and to consolidate divisions so as to form one general county

police establishment,—subject, however, to the power by the queen in council to require the justices to form separate police districts, as provided for in the earlier Acts. The privy council might arrange terms of consolidation of a borough police with the county.

In 1859 provision was made for the abolition of the old office of high constable (the High Constables Act, 1859); and, the establishment of an efficient police having also rendered the general appointment of parish constables unnecessary, the appointment ceased, subject to the appointment by vestries of paid constables who are subject to the chief constable of the county (the Parish Constables Act, 1872). Thus under combined provisions the police system was established and has since continued throughout England.

**Scotland.** In Scotland legislation for a system of police began early in the century by local Acts for Edinburgh and Glasgow, some containing provisions of great importance. The police of towns and populous places is now regulated chiefly by the General Police and Improvement (Scotland) Act, 1862, and the county police by an Act of 1857 (20 & 21 Vict. c. 72), under which counties are formed into police districts. Some details of the government, numbers, and cost have been already given.

**Ireland.** The police in Ireland comprises two forces,—the Dublin metropolitan police and the royal Irish constabulary. Dublin was in 1855 formed into a district called "the police district of Dublin metropolis." (43 Geo. III. c. 146). After intermediate amendments in 1876, concurrently with the consolidation of police law for Ireland generally, the Dublin system was placed on the lines of Sir Robert Peel's Act of 1829 for the metropolis of London,—the chief constable of the local lieutenant standing in the place of the secretary of state for the home department (6 & 7 Will. IV. c. 29); and six years later the system was further assimilated (15 & 16 Vict. c. 22). Several alterations were made subsequently, and police courts regulated. The Dublin police is under the immediate direction of one commissioner and an assistant commissioner, and the offices of receiver and secretary are consolidated. The royal Irish constabulary dates from 1825, when the laws relating to the constabulary force in Ireland were consolidated and a number of other Acts repealed (6 & 7 Will. IV. c. 10). This Act, although often amended, is the foundation of the existing police system in counties, towns, and townships throughout Ireland except in the Dublin metropolitan district. An inspector general, resident in Dublin and having an office there, and appointed by the lord lieutenant, has the general direction of the constabulary, and with the approbation of the lord lieutenant frames rules for their general government, classification, and distribution. In this way a uniform administration of police law prevails throughout Ireland without interfering with the Dublin metropolitan police. Under the inspector general there are a deputy inspector general and assistant inspectors general. The Irish constabulary is regarded as a semi-military force. Every man lives in barracks. It does not interfere with the Dublin metropolitan police, but a reserve force is established at a depot in Dublin. The strength and pay of the force have been already noticed.

**British colonies.** Police forces have been formed in all the British colonies, including the Dominion of Canada, mainly on the lines established in the mother country, having for their basis of action the common law existing there.

The early legislation for Sydney followed very closely the metropolitan police Acts, and some of the existing Acts of the Australian colonies exhibit great skill. Colonial forces generally are sworn to serve the queen, and an Act of the colonial legislature of New South Wales in 1853 made provision for the engagement in Great Britain of persons to serve in the police force of New South Wales. The general features of the Australian police comprise a chief commissioner or other head for each colony or district, appointed by the governor in council, with various grades of officers as at home, some appointed by the governor and the rest by the head of the police. The expense of the police establishments is borne by the colonial revenue (5 & 6 Vict. c. 76, § 46; 13 & 14 Vict. c. 52, § 23).

**British India.** Nearly the whole of British India is divided into police districts, the general arrangements of the system of the regular police resembling in most respects those of the English police, but differing in details in the different presidencies. All are in uniform, trained to the use of firearms, and drilled, and may be called upon to perform military duties. The superior officers are nearly all Europeans, and many of them are military officers. The rest are natives, in Bombay chiefly Mohammedans. The organization of the police was not dealt with by the criminal code which came into force in 1853, but the code is full of provisions tending to make the force efficient. By that code as well as by the former code the police have a legal

sanction for doing what by practice they do in England: they take evidence for their own information and guidance in the investigation of cases, and are clothed with the power to compel the attendance of witnesses and question them. The smallness, of the number of the European magistrates and other circumstances make the police more important and relatively far more powerful in India than in England (Stephen). The difficulties in the way of ascertaining the truth, and investigating false statements and suppressed cases, are very great.

As regards the rural police of India every village headman, and the village watchman as well as the village police officer, are required by the code to communicate to the nearest magistrate or the officer in charge of the nearest police station, whichever is nearest, any information respecting offenders.

Reports indicating an increase in the number of dacoities and crimes of violence since 1880, especially in Rajputana, Central India, and Hyderabad, are cited as proving the necessity for a system of detective police embracing the whole of India. A scheme for that purpose has been matured and will probably be carried out.

Taking Lower Bengal as an illustration of the existing system throughout India, the superior ranks of the police comprise an inspector general, deputies, district superintendents of different grades, assistant superintendents, and probationers. The subordinate officers consist of inspectors of four grades, sub-inspectors (who are in charge of police stations), head constables, and constables. The total budget grant for the year 1881-82 (the last examined) for the police department was 3,695,572 rupees, on a sanctioned strength of 78 superior officers, 3051 subordinate officers, and 14,555 constables, excluding the municipal police but including the civil police and frontier police of the Chittagong hill tracts and the railway police. The strength of the municipal police was 371 officers and 5702 constables. The cost of the force employed on purely police work was 2,154,600 rupees,—the cost per head of the total population being 6-2 pice. The proportion of police to population was in Bengal proper 1 to 3923. The number of offences reported during the year was 104,153. The percentage of reported cases not inquired into is under four.

In India generally, including Assam and British Burmah, the total regular police of all kinds in 1881 was 147,200. The cost was £2,324,765, of which £2,075,525 was payable from imperial or provincial revenues, and the remainder from other sources. The rural police are not paid by the state, but by village cesses.

In Bengal and the Punjab there are 14 policemen to every 100 square miles, and in the North-Western Provinces and Oudh 27. The ratio of these figures is explained partly by the greater density of population and partly by the frequency of crime.

The police force of the British empire, metropolitan, municipal, Total and rural together, is about 210,000. Of this total, 51,000 are in force of the United Kingdom and 147,000 in India, the remainder being British in the colonies and dependencies. If to this total be added the empire number of village police in India who are legally recognized, whose number is not less than 350,000, the grand total of the police for the empire is 560,000. Thus we have for the whole empire an average of one policeman to every 571 of the people and to every 16 square miles (Sir Richard Temple).

The United States of America have a system of police closely United resembling that of England, and founded similarly on Acts of the States. legislature combined with the common law applicable to peace officers. Congress as well as the States separately may establish police regulations, and it is to be observed that the criminal law of England has been reproduced in various shapes in nearly all the States. The source of revenue for the maintenance of the police is taxation of real and personal property. Every State and every city in a State has its separate special administration. For the purposes of this article New York must suffice. The regulations of the police of Brooklyn, Philadelphia, and other cities present the same general features.

The police department of the city of New York consists of a "board of police" composed of four "commissioners" (appointed by the mayor with the consent of the board of aldermen) and the "police force" and officers appointed by the board. The board, consisting of the commissioners, is the head of the police department, and governs and controls its business; it is invested with and exercises all the powers conferred by law upon the police department, makes appointments, and by rules and regulations through a superintendent prescribes the general discipline of the department. The orders cannot, however, conflict with the constitution of the United States nor with the constitution or laws of the State of New York.

The police force of the city comprises officers ranking as follows:—superintendent of the whole force, four inspectors (the whole area of the city being divided into four inspection districts, subdivided into precincts, with an inspector to each), sergeants, and roundsmen, who are visiting officers,—the body of the force being termed "patrol men," with "overmen" at stations and prisons.

The force (clothed in uniform) is divided into as many companies as there are precincts, and such other companies and "squads" as

the board may order. The superintendent is the chief executive officer of the force, subject to the orders, rules, and regulations of the board, and it is his duty to enforce in the city all the laws of the State and ordinances of the city, and the rules and regulations of the police board. The superintendent promulgates written or printed orders to the officers and members of the police force not inconsistent with law or the rules and regulations of the board. It is the duty of the police force at all times of the day and night within the city and county of New York, and they are accordingly empowered, to especially preserve the public peace; prevent crime; detect and arrest offenders; suppress riots and insurrections; protect the rights of persons and of property; guard the public health; preserve order at every primary and public election; remove nuisances existing in public streets, roads, places, and highways; repress and restrain disorderly houses and houses of ill-fame; arrest all street beggars and mendicants; provide a proper police attendance at every fire in order that the firemen, fire-engines, and property exposed may be suitably assisted or protected; assist, advise, and protect immigrants, strangers, and travellers in public streets, or at steamboat and ship landings or railroad stations; enforce any law relating to the suppression and punishment of crime, or to the observance of Sunday, or regarding pawnbrokers, or mock auctions, or emigration, or elections, or gambling, or intemperance, or lotteries, or lottery policies, or vagrants, or disorderly persons, or the public health, or any ordinance or resolution of common councils, within the said district, applicable to police, health, or criminal procedure.

Special regulations are made on these and other kindred subjects, such as the regulation of traffic, preventing obstructions, the visitation of places of amusement, public houses and drinking places, observation of servants in charge of houses, and of suspicious persons, lost children, processions, balls and parties, elections, &c., and the attendance of an adequate number of police at every assembly of citizens.

The arrest of persons with or without process does not call for special notice as distinguished from the common law and statute law in England, and the practice as to the entry of charges and taking bail by the police is akin to the practice in the English metropolis, but the rules are somewhat stricter. A squad is organized for the sole purpose and duty of serving criminal process. Persons making complaint of a felony or misdemeanour may be required to make affirmation or oath which the police officers have power to administer. Charges against police, whether by members of the force or citizens, are made and dealt with under strict rules, and are tried upon written charges by one or more of the commissioners in power, a committee dismissing charges or directing their trial. Evidence is taken upon oath, and if the case is heard by less than three commissioners no judgment can be acted on until the witness is brought before and examined by all the commissioners. The board draws, by its president, on the treasurer of the city for the cost of arrest and conviction of criminals and others endangering the safety of the community and procuring information the use of which may prevent crime and enable the department to perform its important duties more successfully and with greater satisfaction to the public. The sum so drawn is charged as a "secret service fund." A place is provided in accordance with statute law for the detention of such witnesses as are unable to furnish security for their appearance in criminal proceedings.

The detective force, called the "detective squad," consists of a captain and other members assigned by the board to detective duty. This portion of the force has an office, as other portions of the police force, and is under the direct orders of the superintendent, to whom reports are made, and who in turn reports to the board. There is also a "special service squad" under the officer commanding the detective force.

There is a sanitary code, and a "sanitary police company" is set apart from the police force by the board of police, performing duties assigned by the board. The captain of the sanitary company assigns policemen to act as school officers. There are harbour police, a police steamboat and steam-boiler inspection squad to enforce the statute law on the subject, an "ordinance police squad" to enforce ordinances of the corporation, and a "property office."

Members of the force are subject to rules; at the discretion of the board, on written application, they are permitted to receive rewards or presents for services rendered by them in the discharge of duties which are both "meritorious and extraordinary," but for such only. Admission to the force, examination, instruction, drill, and discipline are provided for by special regulations. The right of every member of the police force to entertain political or partisan opinions, and to express the same freely when such expression shall not concern the immediate discharge of his official duties, as well as the right of the elective franchise, is deemed sacred and inviolable; but no member of the force is permitted to be a delegate or representative to, or member of, or to take part in any political or partisan convention, whose purpose is the nomination of a candidate or candidates to any political office. Upon the days of election for public offices held under the laws of the State, he must do all

within his power to preserve the peace, protect the integrity of the ballot box, enforce the rights of lawful voters, and prevent illegal and fraudulent voting.

The estimated salaries for the police of New York for 1884, comprising upwards of 2816 members of the force of all ranks, amounted to \$3,328,333, besides the salaries of the clerical force. The appropriations for the maintenance of the city government (including the police) are made by the board of estimate and apportionment, composed of the mayor, comptroller, president of the board of aldermen, and president of the department of taxes and assessments. Some police statistics are given in the article NEW YORK (q.v.).

Looked at from a general point of view, the police in France may be regarded as divided into two great branches—administrative police (*la police administrative*) and judicial police (*la police judiciaire*),—the former having for its object the maintenance of order, and the latter charged with tracing out offenders, collecting the proofs, and delivering the presumed offenders to the tribunals charged by law with their trial and punishment.

Police duties are exercised under the minister of the interior, in the departments and municipalities by the prefects and sub-prefects, appointed by the president of the republic, and mayors, having as auxiliaries the commissaries of police and other officers (appointed by the president, but under the orders of the prefects). One of the chief prerogatives of the administrative police is to make rules to ensure public order. Of these rules some embrace general interests of the state, these being regulations of high or grand police; others have no other object than the ruling of the particular district and its inhabitants, and are simply termed police regulations. According as it deals with the general interests of the state or only with those of a municipality, the administrative police is said to be general or municipal; and each of these branches admits of other divisions according to the subject. The *police générale*, besides more obvious matters, includes all matters relating to public health, the regulation of prostitution, the inspection of food, the carrying on of trades and manufactures; and in relation to the welfare of the state it embraces public meetings, banquets, societies and clubs; cafés and public places, and the enforcement of laws relating to the publication and distribution of printed or written matter, the sale of journals, the surveillance of strangers or fugitives, the system of passports, the sale of gunpowder and firearms, designs against the state, and a variety of such matters. In this way the police who look after the safety of the state is closely allied with political matters (*la police politique*). Under a government really representing the popular will the duties of the *police politique* are trifling, or at least innocuous, but under a despotic government they become of the highest importance. It is matter of history which cannot be treated of here that under Louis XIV. and in succeeding times the most unpopular and unjustifiable use was made of police as a secret instrument for the purposes of despotic government. Napoleon availed himself largely of police instruments, especially through his minister Fouché. On the restoration of constitutional government under Louis Philippe police action was less dangerous, but the danger revived under the second empire.

The ministry of police created by the act of the Directory in 1796 was in 1818 suppressed as an independent office, and in 1852 it was united with the ministry of the interior.

The detection and punishment of crime is theoretically as well as practically regarded by the French as essentially a matter of public concern, and to be provided for by public officials appointed for that purpose, and on the other hand in every French criminal proceeding, from the most trifling to the most important, every person injured by the offence may make himself *partie civile*. It follows that in many features the French police is organized in a different manner from the British, and has some very different duties (Stephen). An observation has been already cited, that neither in England nor in America is there a system of espionage by which private matters can be made the subject of police investigation or interference. On the other hand the English system is open to the observation that the police, in practice at least, are powerless to protect from annoyance in many matters essential to perfect rule. Short of absolute indecency or obscenity, printed matter of a scurrilous and offensive kind is openly sold in the streets without police interference; and, owing apparently to the much-abused maxim that an Englishman's house is his castle, the quiet and freedom from annoyance in the performance and fulfilling of the daily duties and engagements of life are not secured. The annoyance to which Carlyle was subject is only an illustration of the almost daily complaints that arise in the English metropolis. Although the noise of a bell may be the subject of indictment or injunction, the officers of police do not complain of or even remonstrate with an inconsiderate or selfish neighbour in such a matter, or even in still greater annoyance, such as those arising from animals kept in a state of confinement (not affecting public health), because the source of annoyance is within private territory, or because there is no summary mode of dealing with it. It is unreasonable that complainants should be told, as they are every day, and correctly, by magistrates, that the annoyances which render the enjoyment of life impracticable

may be subject of indictment or injunction, but not of summary police intervention. The fear of drawing down ridicule akin to Vergara's direction in the watch, "If you hear a child cry in the night, you must call to the nurse to hold her still!" probably stands mainly in the way of police interference with real nuisances.

It is not, however, in the minute details of regulation and inspection of the incidents of every day life that the distinctions between the police systems of the two countries chiefly consist. Such distinctions have of late years greatly diminished; the intervention in all matters of health, for example, places the English system more akin to the French, and on the other hand all travelling and mature years in hostility to the mitigation and even total cessation in France, and on the Continent generally, of the minute investigation of a stranger who is not a "suspect." "To the word exploreur a stranger is attached," says Bentham. "Let us not attribute the word inspection, which is unconnected with the same prejudices." If this hope that could do in the minute nature of an oppressively regulated police, which subjects to important or trifling punishment, which condemns secretly and arbitrarily, it is natural that such a system and its agents should become odious. But if the inspection consists in the maintenance of a system of police for the preservation of the public tranquillity and the execution of good laws, all its imperfections and all its paradoxes are a useful and salutary part; it is only the vicious system will have room to complain, and it will be found false to the medium. It is with reference to criminal matters and the police jurisdiction that important distinctions exist between the French and English systems. In every neighbourhood there is a judge of instruction who presides the first formal inquiry in criminal cases, and in every tribunal of last instance, or tribunal of appeal, there is a *procureur de la république* who with deputies forms the *chambre publique* of that court. In the court of the *tribunal de paix* (who may be compared to police magistrates) the counsel of the police is the *chambre publique*. The *juges de paix*, the *procureur*, the counsel of the police, the *gendarmes*, and in rural districts the *gardiens champêtres* and the *gardiens forestiers*, are officers of the judicial police; and by the *Code d'instruction criminelle* all the officers, even the *juges d'instruction*, are under the order of the *procureur général*. The functions of these officers as well as the courts are lately explained in the article *Prison* (vol. ix. p. 511).

*Gendarmes de ville*, in Paris now called *gendarmes de la paix* (the name having been changed thus in September 1879), are the more important of judicial police constables and are not officers of the police jurisdiction. Their powers in preserving the public peace closely resemble the common law powers and duties and protection of the English constable. Their reports of crimes have not the authority of a *procès verbal*.

In Paris, as elsewhere, the *chef de police* is at the head of the force, with *commissaires de police*, appointed by the president of the republic on the nomination of the minister of the Interior, but acting under the order of the prefect, and having both judicial and police duties. The commissaires see that the laws relating to good order and public safety are observed, and that the police orders are executed, and take special action in criminal matters. As officers of the judicial police they are the auxiliaries of the *procureur* of the republic in criminal and criminal police matters, and in the ordinary police tribunal (the *tribunal de simple police*) they exercise the functions of magistrates.

The organization of the central administration (*administration centrale*) comprises three chief functions which together constitute the police. First there is the office or cabinet of the prefect for the general police (the *police générale*), with three bureaux having for their special object the duty of the president of the republic, matters connected with the use of arms, various societies, the regulation and order of public assemblies, the streets, amusements and entertainments, movements of troops, the military police (the *police militaire*), and various other matters; secondly, the judicial police (the *police judiciaire*), who are specially charged with the constant communication with the courts of justice, and including the service of the prisoners of the prison, matters relating to aliens, and the protection of children; thirdly, the administrative police (the *police administrative*), with four bureaux, including everything relating to supplies, regulation, public establishments, markets, hygiene, public health, and the enforcement of the laws relating to the employment of young persons. Some other matters are under the supervision of the prefect of the Seine. Concurrently with the divisions there is the municipal police, which comprises all the agents enforcing police regulations in the street or public thoroughfare, acting under the order of a chief (*chef de la police municipale*) with a central bureau. The municipal police is divided into two principal branches—the *service en uniforme* of the *gendarmes de la paix*, and the *service en civil* of uniformed *inspecteurs de police*, the latter a comparatively small number.

For purposes of municipal police, Paris is divided into twenty arrondissements, each with its division of police, which the uniform police (police),

The total police strength of the Paris arrondissements, according to the latest return, showed 6322 *gendarmes de la paix*, each arrondissement allocated by an *officier de paix* (an officer peculiar to Paris), with 3 or 4 *inspecteurs* and from 24 to 27 *sous-inspecteurs* under his command. There are two divisional inspectors.

Besides these divisional *gendarmes de la paix*, there is a central administration consisting of 6 central *inspecteurs* of 360 each, 4 of the *brigades* carrying out the orders of the prefecture at theatres, assemblies, races, and in the Bois de Boulogne, and elsewhere in the capital where their presence is required, while the 6th brigade regulates traffic generally, and the 5th prevents obstructions in the markets.

The *service de sûreté*, or detective department (not of uniform), with which is now amalgamated the *brigade des mœurs* (which deals with public morals, houses of ill fame, prostitutes, and so forth), comprises a commandary, principal inspectors, *inspecteurs*, and 211 inspectors. There are a number of other branches of service including a fire brigade.

The proportion of police to inhabitants as last recorded is 1 in 322.

The pay of the *gendarmes de la paix* is from 1366 to 1766 francs; *inspecteurs*, 2666 francs; *sous-inspecteurs*, 1866 francs; *officiers de paix*, 2566 to 3666 francs. The estimate of expenditure of the whole Paris police for 1884 was 21,552,531 francs—of which the state contributed 7,511,125 francs.

Whether the police of Paris are more effective than those of the English metropolis is doubtful. Persons who are not entitled to express an opinion, having practical experience, think that, while a multitude of officers and officers for a multitude of subjects and stages of investigation—a system, in short, of *longue durée* exists, which creates an impression, the actual detection of grave offences is not commensurate with the display of attention.

It is impossible in the narrow limits of this article to go through Germany all the police forces of Europe. It must suffice to allude to a few principal states, noting the police force of the respective states illustrating the system. Taking the Berlin force as the basis of the police system in the German empire, police duties are various: in Prussia, the system includes a political police controlling all matters relating to the press, societies, clubs, and public and social amusements. Police duties are divided out under the direction of the royal police presidency, the executive police force comprising a police colonel, with, besides commandants of criminal investigations, capitains, lieutenants, acting lieutenants, sergeant majors, and a large body of constables (*Hehrensleute*). The total in 1874 amounted to 3441 executive officers, including criminal investigation officers, the political police, and the department for the supervision of prostitution. Taking the population of Berlin from the statistical bureau of 27th July 1874 at 1,242,529, this gives 281 to each officer. The pay of the police is generally provided from local sources, and varies in an *arrondissement* from 1125 marks and lodging allowance for the lowest class of constables.

Taking Vienna in the same way as illustrative of the Austrian system, it is to be observed that there are three branches—(1) administrative; (2) public safety and judicial police; and (3) the Government police. At the head of the police service in Vienna stands a president of police, and at the head of each of the three branches there is an *Oberpollsteiger* or chief constable. The head of the Government branch sometimes fills the office of president. Each of the branches is subdivided into departments at the head of which are *Polizeikommissäre*. The superiors of the subdivided branches of the administrative branch, the public safety and judicial branch include the following departments:—the office for public safety, the central inquiry office, and the record office or *Rechtsbureau*. The Government police branch comprises three departments:—the Government police office, the *patrol* office, and the *Verkehrsbureau* or office for the regulation of traffic.

The *Heherhellschutzwache* or executive police of Vienna consists of a central inspector and chief, district, divisional, and other inspectors, with about 2500 constables, *Heherhellschutzwachen*. The detective department comprises a chief and other inspectors, and 319 agents. In July 1874 the proportion of police constables to the inhabitants was 1 to 426. In the last return, the entire police service comprised 216 per cent, at a cost of 2,355,710 florins—of which the state contributed 1,750,746 florins, and the communes the greater part of the remainder. The pay of the constables ranges from 250 florins with allowances of 96 florins.

It is obvious that there is a general resemblance between the organization and scope of the police forces of Germany and Austria and of Prussia.

In Belgian municipalities the *bourgmestres* are the heads of the police forces, which is under their control. The administrator of public safety is, however, specially instructed by the minister of justice to see that the laws and regulations affecting the police are properly carried out, and he can call on all public functionaries to act in furtherance of that object. The administrator of public safety is specially charged with the administration of the law in regard to aliens, and this law is applied, as in the case of Victor Hugo, to

persons stirring up sedition. The duty of the *gendarmérie*, who constitute the horse and foot police, is generally to maintain internal order and peace. In Brussels as elsewhere the burgomaster is the head, but for executive purposes there is a chief commissary (subject, however, to the orders of the burgomaster), with assistant commissaries and commissaries of divisions and other officers, and central and other bureaus, with a body of agents (police constables) in each.

There are two main classes of police functions recognized by law, the administrative and the judicial police, the former engaged in the daily maintenance of peace and order and so preventing offences, the latter in the investigation of crime and tracing offenders; but the duties are necessarily performed to a great extent by the same agents. The two other functions of the judicial police are, however, limited to the same classes of officers, and they perform the same duties as in Paris,—the law in practice there being expressly adopted in Brussels.

In Brussels the police force numbers, according to the latest report, 485 of all ranks. For the population (162,489), this gives 1 to every 335 persons. Strictly speaking there is no detective branch so called, but the special and judicial officers are employed in detection as the necessity arises. The pay and establishment charges are defrayed by local taxation. The annual pay of a constable is 1500 francs.

While this article is going through the press the idea is put forward, in consequence of political disturbances, to place the police of the larger Belgian towns under the control of Government instead of that of the respective municipalities as at present, and establish a sort of prefecture of police in Brussels. The attempt, if made, will probably meet with opposition from local authorities.

Switzerland. In Switzerland, which is sometimes classed with Belgium as among the least policed states of Europe, the laws of the cantons vary. In some respects they are stricter than in Belgium or even in France. Thus a *permis de séjour* is sometimes required where none is in practice necessary in Paris or Brussels.

Italy. In Italy there is in every province a prefect at the head of the police. See ITALY.

Netherlands. The police in the Netherlands, as regards the sources from which its powers are derived, is divided into the state police and the communal police, the former forming part of the general executive government, and the latter, although regulated by the executive, enforcing general and local police legislation. Regulations for the state police are framed by the minister of justice. For the purposes of the state police the country is divided into five districts, with a director of police at the head of each district responsible for the control and government of the state police within it, and to see that the laws and ordinances for the safety and quietness of the state, the security of persons and property, and the equality of all before the law are carried out. The duty specially includes the supervision of strangers and their admission into and departure from the country, and extends even to the enforcement of shooting and fishing licences. In each district there is an officer of justice who directs the prosecution of criminal offences.

At the head of the communal police stand the burgomasters, and under them police commissaries entrusted with the observance of police regulations, whose appointment and removal rest with the crown, but they are paid by the commune. The whole of the communal police are bound to assist the state police; and, on the other hand, the latter assist the police, especially in the country districts. The duties of the officer of justice may be carried out by the commissary of police, who for the time being is an assistant officer of justice. In large communes the police force is divided into several grades. Besides commissaries, of whom one is chief, there are a chief inspector, classes of inspectors, and brigadiers; but the arrangements differ in almost every municipality.

The total strength of the police is 6000; at The Hague there is supposed to be one constable to 1000 inhabitants. Only in Amsterdam, Rotterdam, and The Hague are there special departments of detective police. Police salaries vary in different communes. The highest are at The Hague, and range from 600 florins for a third-class constable to 1800 florins for a chief inspector. The cost of the state police and the expenses incurred in prosecutions for crime are defrayed by the state. The expenses of the communal police are paid out of local rates on houses and land.

Russia. An official Russian document specially obtained for this article affords the following scanty particulars regarding the police in European Russia.

At the head of a police district there is a police master, who has subordinate officers on his staff. A number of constables are appointed, depending on the population. Large towns are subdivided into districts with inspectors and assistants, smaller towns with an assistant inspector. In villages police duties are executed by the inhabitants elected for that purpose, constituting "hundreds" or "tenths" according to the number of inhabitants. There is a control over the villages by the police of the district, and the governor general has a controlling power over all, including the police master. Besides the ordinary police there are police brigades

in large towns with duties of a special kind, as attending parades and fêtes. Each member of the brigade has five hundred inhabitants to look after or control. In the capitals there is a secret police having a staff in St Petersburg of a chief and his assistant, four clerks, and twenty inspectors, and in Moscow of a chief, two clerks, and twelve inspectors.

The principal active duties of the Russian police comprise the enforcement of police laws and the suppression of nuisances, disturbances, and crime. The details of these duties are laid down in a special Act, which is subdivided into different statutes, taken from the criminal code. The provincial towns are governed by a special law, passed in 1876, as supplementary to the already existing law. The towns provide the funds for the maintenance of the police. Laws of 1853 regulated the lodgings and necessaries for the whole police staff according to their rank; but a change has been introduced since 1873, and many officers receive payment in the place of lodgings. Police pay varies from 200 roubles upwards.

In closing this article, it is well to observe that the distinction between the exercise of judicial power and police functions should be always borne in mind. "The functions of justice and those of the police must be apt in many points to run into one another, especially as the business would be very badly managed if the same persons whose more particular duty it is to act as officers of the police were not upon occasion to act in the capacity of officers of justice. The idea, however, of the two functions may still be kept distinct" (Bentham). The employment of police powers in the ante-judicial part of criminal process, which previously to the establishment of a police force in England was thought to require an apology as founded on convenience and utility rather than on principle, has become a necessity.

The necessity for a police force as part of any system of orderly government is exemplified by its recent introduction into Egypt. Amid differences of opinion on every subject, and even on the administration of the force and its duties, the abstract propriety of a police force is apparently beyond dispute.

In every country the difficult question, apart from any as to the extent of interference with the freedom of individual action, arises in actual police administration—*Quis custodiet ipsos custodes?*

By whatever name the head of a police force is known, whether as commissioner, chief constable, superintendent, or otherwise, the efficient performance of his duty involves inquiry, and judgment upon that inquiry. The character and efficiency of his force must largely depend upon the insight as well as vigour brought to bear upon the individual members of that force.

In relation to the public generally a perfect police code must be full of restraints, with coextensive powers of inquiry, even in matters that do not involve punishment. The extent to which these restraints and powers are applied greatly depends on time and place. Precautions which are necessary, Bentham observes, at certain periods of danger and trouble, ought not to be continued in a period of quietness, and care should be taken not to shock the national spirit. One nation would not endure what is borne by another.

(J. E. D.)

POLIGNAC, an ancient French family, which had its seat in the Cevennes near Puy-en-Velay (Haute-Loire). Cardinal MELCHIOR DE POLIGNAC (1661-1742) was a younger son of Armand XVI, marquis de Polignac, and at an early age achieved distinction as a diplomatist. In 1695 he was sent as ambassador to Poland, where he contrived to bring about the election of the prince of Conti as successor to John Sobieski (1697). The subsequent failure of this intrigue led to his temporary disgrace, but in 1702 he was restored to favour, and in 1712 he was sent as the plenipotentiary of Louis XIV. to the congress of Utrecht. During the regency he became involved in the Cellamare plot, and was relegated to Flanders for three years. From 1725 to 1732 he acted for France at the Vatican. In

1726 he received the archbishopric of Auch, and he died at Paris in 1742. He left unfinished a motrical refutation of Lucretius which was published after his death by the Abbé de Rothelin (*Anti-Lucretius*, 1745), and had considerable vogue in its day. Count JULES DE POLIGNAC (ob. 1817), grand-nephew of the preceding, was created duke by Louis XVI. in 1780, and in 1782 was made postmaster-general. His position and influence at court were largely due to his wife, the bosom friend of Marie Antoinette; the duke and duchess alike shared the unpopularity of the court, and were among the first who were compelled to "emigrate" in 1789. The duchess died shortly after the queen, but her husband, who had received an estate from Catherine II. in the Ukraine, survived till 1817. Of their three sons the second, Prince JULES DE POLIGNAC (1780-1847), held various offices after the restoration of the Bourbons, received from the pope his title of "prince" in 1820, and in 1823 was made ambassador to the court of St James's. In August 8, 1829, he was called by Charles X. to the ministry of foreign affairs, and in the following November he became president of the council. On the revolution of July 1830 he fled for his life, but after wandering for some time among the wilds of Normandy was arrested at Granville. His trial before the chamber of peers resulted in his condemnation to perpetual imprisonment (at Ham), but he benefited by the amnesty of 1836, when the sentence was commuted to one of exile. During his captivity he wrote *Considerations politiques* (1832). He afterwards spent some years in England, but finally was permitted to re-enter France on condition that he did not take up his abode in Paris. He died at St Germain on March 29, 1847.

POLILLO. See PHILIPPINE ISLANDS.

POLITIAN (1454-1494). Angelo Ambrogini, known in literary annals as ANGELO POLIZIANO or POLITIANUS from his birth-place, was born at Montepulciano in Tuscany in the year 1454. His father, Benedetto, a jurist of good family and distinguished ability, was murdered by political antagonists for adopting the cause of Piero de' Medici in Montepulciano; and this circumstance gave his eldest son, Angelo, a claim on the family of Medici. At the age of ten the boy came to prosecute his studies at Florence, where he learned Latin under Cristoforo Landino, and Greek under Argyropoulos and Andronikos Kallistos. From Marsilio Ficino he imbibed the rudiments of philosophy. The precocity of his genius for scholarship and poetry was early manifested. At thirteen years of age he began to circulate Latin letters; at seventeen he sent forth essays in Greek versification; at eighteen he published an edition of Catullus. In 1470 he won for himself the title of *Homericus juvenis* by translating four books of the *Iliad* into Latin hexameters. Lorenzo de' Medici, who was then the autocrat of Florence and the chief patron of learning in Italy, took Poliziano into his household, made him the tutor of his children, and secured him a distinguished post in the university of Florence. Before he reached the age of thirty, Poliziano expounded the humanities with almost unexampled lustre even for that epoch of brilliant professors. Among his pupils could be numbered the chief students of Europe, the men who were destined to carry to their homes the *spolia opima* of Italian culture. Not to mention Italians, it will suffice to record the names of the German Reuchlin, the English Grocyn and Linacre, and the Portuguese Tassinari. Poliziano had few advantages of person to recommend him. He was ungainly in form, with eyes that squinted, and a nose of disproportionate length. Yet his voice was rich and capable of fine modulation; his eloquence, ease of utterance, and copious stream of erudition were incomparable. It was the method of

professors at that period to read the Greek and Latin authors with their class, dictating philological and critical notes, emending corrupt passages in the received texts, offering elucidations of the matter, and pouring forth stores of acquired knowledge regarding the laws, manners, religious and philosophical opinions of the ancients. Poliziano covered nearly the whole ground of classical literature during the years of his professorship, and published the notes of his courses upon Ovid, Suetonius, Statius, the younger Pliny, Quintilian, and the writers of Augustan histories. He also undertook a recension of the text of the *Pandects* of Justinian, which formed the subject of one of his courses; and this recension, though it does not rank high in the scale of juristic erudition, gave an impulse to the scholarly criticism of the Roman code. At the same time he was busy as a translator from the Greek. His versions of Epictetus, Herodian, Hippocrates, Galen, Plutarch's *Eroticus*, and Plato's *Charmides* delighted contemporaries by a certain limpid fluency of Latin style and grace of manner which distinguished him also as an original writer. Of these learned labours the most universally acceptable to the public of that time were a series of discursive essays on philology and criticism, first published in 1489 under the title of *Miscellanea*. They had an immediate, a lasting, and a wide renown, encouraging the scholars of the next century and a half to throw their occasional discoveries in the field of scholarship into a form at once so attractive and so instructive. Poliziano was not, however, contented with these simply professorial and scholastic compositions. Nature had endowed him with literary and poetic gifts of the highest order. These he devoted to the composition of Latin and Greek verses, which count among the best of those produced by men of modern times in rivalry with ancient authors. The *Manto*, in which he pronounced a panegyric of Virgil; the *Ambra*, which contains a beautiful idyllic sketch of Tuscan landscape, and a studied eulogy of Homer; the *Rusticus*, which celebrated the pleasures of country life in no frigid or scholastic spirit; and the *Nutricia*, which was intended to serve as a general introduction to the study of ancient and modern poetry,—these are the masterpieces of Poliziano in Latin verse, displaying an authenticity of inspiration, a sincerity of feeling, and a command of metrical resources which mark them out as original productions of poetic genius rather than as merely professorial lucubrations. Exception may be taken to their style, when compared with the best work of the Augustan or even of the Silver age. But what renders them always noteworthy to the student of modern humanistic literature is that they are in no sense imitative or conventional, but that they convey the genuine thoughts and emotions of a born poet in Latin diction and in metre moulded to suit the characteristics of the singer's temperament.

Poliziano was great as a scholar, as a professor, as a critic, and as a Latin poet at an age when the classics were still studied with the passion of assimilative curiosity, and not with the scientific industry of a later period. He was the representative hero of that age of scholarship in which students drew their ideal of life from antiquity and fondly dreamed that they might so restore the past as to compete with the classics in production and bequeath a golden age of resuscitated paganism to the modern world. Yet he was even greater as an Italian poet. Between Boccaccio and Ariosto, no single poet in the mother tongue of Italy deserves so high a place as Poliziano. What he might have achieved in this department of literature had he lived at a period less preoccupied with humanistic studies, and had he found a congenial sphere for his activity, can only be guessed. As it is, we must reckon him as decidedly the foremost and indubitably the most highly gifted among the Italian poets who obeyed Lorenzo

de' Medici's demand for a resuscitation of the vulgar literature. Lorenzo led the way himself, and Poliziano was more a follower in his path than an initiator. Yet what Poliziano produced, impelled by a courtly wish to satisfy his patron's whim, proves his own immeasurable superiority as an artist. His principal Italian works are the stanzas called *La Giostra*, written upon Giuliano de' Medici's victory in a tournament; the *Orfeo*, a lyrical drama performed at Mantua with musical accompaniment; and a collection of fugitive pieces, reproducing various forms of Tuscan popular poetry. *La Giostra* had no plan, and remained imperfect; but it demonstrated the capacities of the octave stanza for rich, harmonious, and sonorous metrical effect. The *Orfeo* is a slight piece of work, thrown off at a heat, yet abounding in unpremeditated lyrical beauties, and containing in itself the germ both of the pastoral play and of the opera. The Tuscan songs are distinguished by a "roseate fluency," an exquisite charm of half romantic half humorous abandonment to fancy, which mark them out as improvisations of genius. It may be added that in all these departments of Italian composition Poliziano showed how the taste and learning of a classical scholar could be engrafted on the stock of the vernacular, and how the highest perfection of artistic form might be attained in Italian without a sacrifice of native spontaneity and natural flow of language.

It is difficult to combine in one view the several aspects presented to us by this many-sided man of literary genius. At a period when humanism took the lead in forming Italian character and giving tone to European culture, he climbed with facility to the height of achievement in all the branches of scholarship which were then most seriously prized—in varied knowledge of ancient authors, in critical capacity, in rhetorical and poetical exuberance. This was enough at that epoch to direct the attention of all the learned men of Europe on Poliziano. At the same time, almost against his own inclination, certainly with very little enthusiasm on his part, he lent himself so successfully to Lorenzo de' Medici's scheme for resuscitating the decayed literature of Tuscany that his slightest Italian

effusions exercised a potent influence on the immediate future. He appears before us as the dictator of Italian culture in a double capacity—as the man who most perfectly expressed the Italian conception of humanism, and brought erudition into accord with the pursuit of noble and harmonious form, and also as the man whose vernacular compositions were more significant than any others of the great revolution in favour of Italian poetry which culminated in Ariosto. Beyond the sphere of pure scholarship and pure literature Poliziano did not venture. He was present, indeed, at the attack made by the Pazzi conspirators on the persons of Lorenzo and Giuliano de' Medici, and wrote an interesting account of its partial success. He also contributed a curious document on the death of Lorenzo de' Medici to the students of Florentine history. But he was not, like many other humanists of his age, concerned in public affairs of state or diplomacy, and he held no office except that of professor at Florence. His private life was also uneventful. He passed it as a house-friend and dependant of the Medici, as the idol of the learned world, and as a simple man of letters for whom (with truly Tuscan devotion to the Saturnian country) rural pleasures were always acceptable. He was never married; and his morals incurred suspicion, to which his own Greek verses lend a certain amount of plausible colouring. In character Poliziano was decidedly inferior to the intellectual and literary eminence which he displayed. He died half broken-hearted by the loss of his friend and patron Lorenzo de' Medici, in 1494, at the age of forty, just before the wave of foreign invasion which was gathering in France swept over Italy.

For the life and works of Politian, consult F. O. Mencken (Leipzig, 1736), a vast repository of accumulated erudition; Jac. Mahly, *Angelus Politianus* (Leipzig, 1864); Carducci's edition of the Italian poems (Florence, Barbera, 1863); Del Lungo's edition of the Italian prose works and Latin and Greek poems (Florence, Barbera, 1867); the *Opera Omnia* (Basel, 1554); Gresswell's *English Life of Politian*; Roscoe's *Lorenzo de' Medici*; Von Reumont's *Life of Lorenzo de' Medici*; Symonds's *Renaissance in Italy*, and translations from Poliziano's Italian poems in his *Sketches and Studies in Italy*, which include the *Orfeo*.  
(J. A. S.)

## P O L I T I C A L   E C O N O M Y

THE present condition of the study of political economy seems to prescribe, as most suitable for these pages, a treatment of the subject different from that adopted in relation to other departments of knowledge. There prevails wide-spread dissatisfaction with the existing state of economic science, and much difference of opinion both as to its method and as to its doctrines. There is, in fact, reason to believe that it has now entered on a transition stage, and is destined ere long to undergo a considerable transformation. Hence it has appeared to be unseasonable, and therefore inexpedient, to attempt in this place a new dogmatic treatise on political economy. What is known as the "orthodox" or "classical" system, though in our time very generally called in question, is to be found set out in numerous text-books accessible to every one. Again, some of the most important special branches of economics are so fully explained and discussed in other parts of the present work (see *BANKING, EXCHANGE, FINANCE, MONEY, &c.*) as to dispense with any further treatment of them here. It has been thought that the mode of handling the subject most appropriate to the circumstances of the case, and likely to be most profitable, would be that of tracing historically from a general point of view the course of speculation regarding economic phenomena, and contemplating the successive forms of opinion concerning them as products of the periods at which they were respectively evolved.

Such a study is in harmony with the best intellectual tendencies of our age, which is, more than anything else, characterized by the universal supremacy of the historical spirit. To such a degree has this spirit permeated all our modes of thinking that with respect to every branch of knowledge, no less than with respect to every institution and every form of human activity, we almost instinctively ask, not merely what is its existing condition, but what were its earliest discoverable germs, and what has been the course of its development? The assertion of J. B. Say that the history of political economy is of little value, being for the most part a record of absurd and justly exploded opinions, belongs to a system of ideas already obsolete, and requires at the present time no formal refutation. It deserves notice only as reminding us that we must discriminate between history and antiquarianism: what from the first had no significance it is mere pedantry to study now. We need concern ourselves only with those modes of thinking which have prevailed largely and seriously influenced practice in the past, or in which we can discover the roots of the present and the future.

When we thus place ourselves at the point of view of history, it becomes unnecessary to discuss the definition of political economy, or to enlarge on its method, at the outset. It will suffice to conceive it as the theory of social wealth, or to accept provisionally Say's definition which

makes it the science of the production, distribution, and consumption of wealth. Any supplementary ideas which require to be taken into account will be suggested in the progress of our survey, and the determination of the proper method of economic research will be treated as one of the principal results of the historical evolution of the science.

The history of political economy must of course be distinguished from the economic history of mankind, or of any separate portion of our race. The study of the succession of economic facts themselves is one thing; the study of the succession of theoretic ideas concerning the facts is another. And it is with the latter alone that we are here directly concerned. But these two branches of research, though distinct, yet stand in the closest relation to each other. The rise and the form of economic doctrines have been largely conditioned by the practical situation, needs, and tendencies of the corresponding epochs. With each important social change new economic questions have presented themselves; and the theories prevailing in each period have owed much of their influence to the fact that they seemed to offer solutions of the urgent problems of the age. Again, every thinker, however in some respects he may stand above or before his contemporaries; is yet a child of his time, and cannot be isolated from the social medium in which he lives and moves. He will necessarily be affected by the circumstances which surround him, and in particular by the practical exigencies of which his fellows feel the strain. This connexion of theory with practice has its advantages and its dangers. It tends to give a real and positive character to theoretic inquiry; but it may also be expected to produce exaggerations in doctrine, to lend undue prominence to particular sides of the truth, and to make transitory situations or temporary expedients be regarded as universally normal conditions.

There are other relations which we must not overlook in tracing the progress of economic opinion. The several branches of the science of society are so closely connected that the history of no one of them can with perfect rationality be treated apart, though such a treatment is recommended—indeed necessitated—by practical utility. The movement of economic thought is constantly and powerfully affected by the prevalent mode of thinking, and even the habitual tone of sentiment, on social subjects generally. All the intellectual manifestations of a period in relation to human questions have a kindred character, and bear a certain stamp of homogeneity, which is vaguely present to our minds when we speak of the spirit of the age. Social speculation again, and economic research as one branch of it, is both through its philosophic method and through its doctrine under the influence of those simpler sciences which in the order of development precede the social, especially of the science of organic nature.

It is of the highest importance to bear in mind these several relations of economic research both to external circumstance and to other spheres of contemporary thought, because by keeping them in view we shall be led to form less absolute and therefore juster estimates of the successive phases of opinion. Instead of merely praising or blaming these according to the degrees of their accordance with a predetermined standard of doctrine, we shall view them as elements in an ordered series, to be studied mainly with respect to their filiation, their opportuneness, and their influences. We shall not regard each new step in this theoretic development as implying an unconditional negation of earlier views, which often had a relative justification, resting, as they did, on a real, though narrower, basis of experience, or assuming the existence of a different social order. Nor shall we consider all the theoretic posi-

tions now occupied as definitive; for the practical system of life which they tacitly assume is itself susceptible of change, and destined, without doubt, more or less to undergo it. Within the limits of a sketch like the present these considerations cannot be fully worked out; but an effort will be made to keep them in view, and to mark the relations here indicated, wherever their influence is specially important or interesting.

The particular situation and tendencies of the several thinkers whose names are associated with economic doctrines have, of course, modified in a greater or less degree the spirit or form of those doctrines. Their relation to special predecessors, their native temperament, their early training, their religious prepossessions and political partialities, have all had their effects. To these we shall in some remarkable instances direct attention; but, in the main, they are, for our present purpose, secondary and subordinate. The *ensemble* must preponderate over the individual; and the constructors of theories must be regarded as organs of a common intellectual and social movement.

The history of economic inquiry is most naturally divided into the three great periods of (1) the ancient, (2) the mediæval, and (3) the modern worlds. In the two former, this branch of study could exist only in a rudimentary state. It is evident that for any considerable development of social theory two conditions must be fulfilled. First, the phenomena must have exhibited themselves on a sufficiently extended scale to supply adequate matter for observation, and afford a satisfactory basis for scientific generalizations; and secondly, whilst the spectacle is thus provided, the spectator must have been trained for his task, and armed with the appropriate aids and instruments of research, that is to say, there must have been such a previous cultivation of the less complex sciences as will have both furnished the necessary data of doctrine and prepared the proper methods of investigation. Sociology requires to use for its purposes theorems which belong to the domains of physics and biology, and which it must borrow from their professors; and, on the logical side, the methods which it has to employ—deductive, observational, comparative—must have been previously shaped in the cultivation of mathematics and the study of the inorganic world or of organisms less complex than the social. Hence it is plain that, though some laws or tendencies of society must have been forced on men's attention in every age by practical exigencies which could not be postponed, and though the questions thus raised must have received some empirical solution, a really scientific sociology must be the product of a very advanced stage of intellectual development. And this is true of the economic, as of other branches of social theory. We shall therefore content ourselves with a general outline of the character of economic thought in antiquity and the Middle Ages, and of the conditions which determined that character.

#### ANCIENT TIMES.

*The Oriental Theocracies.*—The earliest surviving expressions of thought on economic subjects have come down to us from the Oriental theocracies. The general spirit of the corresponding type of social life consisted in taking imitation for the fundamental principle of education, and consolidating nascent civilization by heredity of the different functions and professions, or even by a system of castes, hierarchically subordinated to each other according to the nature of their respective offices, under the common supreme direction of the sacerdotal caste. This last was charged with the traditional stock of conceptions, and their application for purposes of discipline. It sought to realize a com-

plete regulation of human life in all its departments on the basis of this transmitted body of practical ideas. Conservation is the principal task of this social order, and its most remarkable quality is stability, which tends to degenerate into stagnation. But there can be no doubt that the useful arts were long, though slowly, progressive under this regime, from which they were inherited by the later civilizations,—the system of classes or castes maintaining the degree of division of labour which had been reached in those early periods. The eminent members of the corporations which presided over the theocracies without doubt gave much earnest thought to the conduct of industry, which, unlike war, did not imperil their political pre-eminence by developing a rival class. But, conceiving life as a whole, and making its regulation their primary aim, they naturally considered most the social reactions which industry is fitted to exercise. The moral side of economics is the one they habitually contemplate, or (what is not the same) the economic side of morals. They abound in those warnings against greed and the haste to be rich which religion and philosophy have in all ages seen to be necessary. They insist on honesty in mutual dealings, on just weights and measures, on the faithful observance of contracts. They admonish against the pride and arrogance apt to be generated by riches, against undue prodigality and self-indulgence, and enforce the duties of justice and beneficence towards servants and inferiors. Whilst, in accordance with the theological spirit, the personal acquisition of wealth is in general thesis represented as determined by divine wills, its dependence on individual diligence and thrift is emphatically taught. There is indeed in the fully developed theocratic systems a tendency to carry precept, which there differs little from command, to an excessive degree of minuteness,—to prescribe in detail the time, the mode, and the accompaniments of almost every act of every member of the community. This system of exaggerated surveillance is connected with the union, or rather confusion, of the spiritual and temporal powers, whence it results that many parts of the government of society are conducted by direct injunction or restraint, which at a later stage are intrusted to general intellectual and moral influences.

*Greek and Roman Antiquity.*—The practical economic enterprises of Greek and Roman antiquity could not, even independently of any special adverse influences, have competed in magnitude of scale or variety of resource with those of modern times. The unadvanced condition of physical science prevented a large application of the less obvious natural powers to production, or the extensive use of machinery, which has acquired such an immense development as a factor in modern industry. The imperfection of geographical knowledge and of the means of communication and transport were impediments to the growth of foreign commerce. These obstacles arose necessarily out of the mere immaturity of the industrial life of the periods in question. But more deeply rooted impediments to a vigorous and expansive economic practical system existed in the characteristic principles of the civilization of antiquity. Some writers have attempted to set aside the distinction between the ancient and modern worlds as imaginary or unimportant, and, whilst admitting the broad separation between ourselves and the theocratic peoples of the East, to represent the Greeks and Romans as standing on a substantially similar ground of thought, feeling, and action with the Western populations of our own time. But this is a serious error, arising from the same too exclusive preoccupation with the cultivated classes and with the mere speculative intellect which has often led to an undue disparagement of the Middle Ages. There is this essential difference between the spirit and

life of ancient and of modern communities, that the former were organized for war, the latter during their whole history have increasingly tended to be organized for industry, as their practical end and aim. The profound influence of these differing conditions on every form of human activity must never be overlooked or forgotten. With the military constitution of ancient societies the institution of slavery was essentially connected. Far from being an excrescence on the contemporary system of life, as it was in the modern West Indies or the United States of America, it was so entirely in harmony with that life that the most eminent thinkers regarded it as no less indispensable than inevitable. It does, indeed, seem to have been a temporary necessity, and on the whole, regard being had to what might have taken its place, a relative good. But it was attended with manifold evils. It led to the prevalence amongst the citizen class of a contempt for industrial occupations; every form of production, with a partial exception in favour of agriculture, was branded as unworthy of a free man,—the only noble forms of activity being those directly connected with public life, whether military or administrative. Labour was degraded by the relegation of most departments of it to the servile class, above whom the free artisans were but little elevated in general esteem. The agents of production, being for the most part destitute of intellectual cultivation and excluded from any share in civic ideas, interests, or efforts, were unfitted in character as well as by position for the habits of skilful combination and vigorous initiation which the progress of industry demands. To this must be added that the comparative insecurity of life and property arising out of military habits, and the consequent risks which attended accumulation, were grave obstructions to the formation of large capitals, and to the establishment of an effective system of credit. These causes conspired with the undeveloped state of knowledge and of social relations in giving to the economic life of the ancients the limitation and monotony which contrast so strongly with the inexhaustible resource, the ceaseless expansion, and the thousandfold variety of the same activities in the modern world. It is, of course, absurd to expect incompatible qualities in any social system; each system must be estimated according to the work it has to do. Now the historical vocation of the ancient civilization was to be accomplished, not through industry, but through war, which was in the end to create a condition of things admitting of its own elimination and of the foundation of a regime based on pacific activity.

*The Greeks.*—This office was, however, reserved for Rome, as the final result of her system of conquest; the military activity of Greece, though continuous, was incoherent and sterile, except in the defence against Persia, and did not issue in the accomplishment of any such social mission. It was, doubtless, the inadequacy of the warrior life, under these conditions, to absorb the faculties of the race, that threw the energies of its most eminent members into the channel of intellectual activity, and produced a singularly rapid evolution of the æsthetic, philosophic, and scientific germs transmitted by the theocratic societies.

In the *Works and Days* of Hesiod, we find an order of thinking in the economic sphere very similar to that of the theocracies. With a recognition of the divine disposing power, and traditional rules of sacerdotal origin, is combined practical sagacity embodied in precept or proverbial saying. But the development of abstract thought, beginning from the time of Thales, soon gives to Greek culture its characteristic form, and marks a new epoch in the intellectual history of mankind.

The movement was now begun, destined to mould the whole future of humanity, which, gradually sapping the

old hereditary structure of theological convictions, tended to the substitution of rational theories in every department of speculation. The eminent Greek thinkers, while taking a deep interest in the rise of positive science, and most of them studying the only science—that of geometry—then assuming its definitive character, were led by the social exigencies which always powerfully affect great minds to study with special care the nature of man and the conditions of his existence in society. These studies were indeed essentially premature; a long development of the inorganic and vital sciences was necessary before sociology or morals could attain their normal constitution. But by their prosecution amongst the Greeks a noble intellectual activity was kept alive, and many of those partial lights obtained for which mankind cannot afford to wait. Economic inquiries, along with others, tended towards rationality: Plato was dethroned, and terrestrial substituted for supernatural agencies. But such inquiries, resting on no sufficiently large basis of practical life, could not attain any considerable results. The military constitution of society, and the existence of slavery, which was related to it, leading, as has been shown, to a low estimate of productive industry, turned away the habitual attention of thinkers from that domain. On the other hand, the absorption of citizens in the life of the state, and their preoccupation with party struggles, brought questions relating to politics, properly so called, into special prominence. The principal writers on social subjects are therefore almost exclusively occupied with the examination and comparison of political constitutions, and with the search after the education best adapted to train the citizen for public functions. And we find, accordingly, in them no systematic or adequate handling of economic questions,—only some happy ideas and striking partial anticipations of later research.

In their thinking on such questions, as on all sociological subjects, the following general features are observable.

1. The individual is conceived as subordinated to the state, through which alone his nature can be developed and completed, and to the maintenance and service of which all his efforts must be directed. The great aim of all political thought is the formation of good citizens; every social question is studied primarily from the ethical and educational point of view. The citizen is not regarded as a producer, but only as a possessor, of material wealth; and this wealth is not esteemed for its own sake or for the enjoyments it procures, but for the higher moral and public aims to which it may be made subservient.

2. The state, therefore, claims and exercises a controlling and regulating authority over every sphere of social life, including the economic, in order to bring individual action into harmony with the good of the whole.

3. With these fundamental notions is combined a tendency to attribute to institutions and to legislation an unlimited efficacy, as if society had no spontaneous tendencies, but would obey any external impulse, if impressed upon it with sufficient force and continuity.

Every eminent social speculator had his ideal state, which approximated to or diverged from the actual or possible, according to the degree in which a sense of reality and a positive habit of thinking characterized the author.

The most celebrated of these ideal systems is that of Plato. In it the Greek idea of the subordination of the individual to the state appears in its most extreme form. In that class of the citizens of his republic who represent the highest type of life, community of property and of wives is established, as the most effective means of suppressing the sense of private interest, and consecrating the individual entirely to the public service. It cannot perhaps be truly said that his scheme was incapable of realization in an ancient community favourably situated for the purpose. But it would soon be broken to pieces by the forces which would be developed in an industrial society. It has however, been the fruitful parent

of modern Utopias, specially attractive as it is to minds in which the literary instinct is stronger than the scientific judgment, in consequence of the freshness and brilliancy of Plato's exposition and the unrivalled charm of his style. Mixed with what we should call the chimerical ideas in his work, there are many striking and elevated moral conceptions, and, what is more to our present purpose, some just economic analyses. In particular, he gives a correct account of the division and combination of employments, as they naturally arise in society. The foundation of the social organization he traces, perhaps, too exclusively to economic grounds, not giving sufficient weight to the disinterested social impulses in men which tend to draw and bind them together. But he explains clearly how the different wants and capacities of individuals demand and give rise to mutual services, and how, by the restriction of each to the sort of occupation to which, by his position, abilities, and training, he is best adapted, everything useful for the whole is more easily and better produced or obtained. In the spirit of all the ancient legislators he desires a self-sufficing state, protected from unnecessary contacts with foreign populations, which might tend to break down its internal organization or to deteriorate the national character. Hence he discommences foreign trade, and with this view removes his ideal city to some distance from the sea. The limits of its territory are rigidly fixed, and the population is restrained by the prohibition of early marriages, by the exposure of infants, and by the maintenance of a determinate number of individual lots of land in the hands of the citizens who cultivate the soil. These precautions are inspired more by political and moral motives than by the Malthusian fear of failure of subsistence. Plato aims, as far as possible, at equality of property amongst the families of the community which are engaged in the immediate prosecution of industry. This last class, as distinguished from the governing and military classes, he holds, according to the spirit of his age, in but little esteem; he regards their habitual occupations as tending to the degeneration of the mind and the enfeeblement of the body, and wishing those who follow them unfit for the higher duties of men and citizens. The lowest forms of labour he would commit to foreigners and slaves. Again in the spirit of ancient theory, he wishes (*Legis.*, v. 12) to banish the precious metals, as far as practically, from use in internal commerce, and forbids the lending of money on interest, leaving indeed to the free will of the debtor even the repayment of the capital of the loan. All economic dealings he subjects to active control on the part of the Government, not merely to prevent violence and fraud, but to check the growth of luxurious habits, and secure to the population of the state a due supply of the necessities and comforts of life.

Contrasted with the exaggerated idealism of Plato is the somewhat limited but eminently practical genius of Xenophon. In him the man of action predominates, but he has also a large element of the speculative tendency and talent of the Greek. His treatise entitled *Oeconomicus* is well worth reading for the interesting and animated picture it presents of some aspects of contemporary life, and is justly praised by Sismondi for the spirit of mild philanthropy and tender piety which breathes through it. But it scarcely passes beyond the bounds of domestic economy, though within that limit its author exhibits much sound sense and sagacity. His precepts for the judicious conduct of private property do not concern us here, nor his wise suggestions for the government of the family and its dependants. Yet it is in this narrower sphere and in general in the concrete domain that his chief excellence lies; to economics in their wider aspects he does not contribute much. He shows the ordinary preference of his fellow countrymen for agriculture over other employments, and is, indeed, enthusiastic in his praises of it as developing patriotic and religious feeling and a respect for property, as the best preparation for military life, and as leaving sufficient time and thought disposable to admit of considerable intellectual and political activity. Yet his practical sense leads him to attribute greater importance than most other Greek writers to manufactures, and still more to trade, to enter more largely on questions relating to their conditions and development, and to bespeak for them the countenance and protection of the state. Though his views on the nature of money are vague and in some respects erroneous, he sees that its export in exchange for commodities will not impoverish the community. He also insists on the necessity, with a view to a flourishing commerce with other countries, of peace, of a courteous and respectful treatment of foreign traders, and of a prompt and equitable decision of their legal suits. The institution of slavery he of course recognizes and does not disapprove; he even recommends, for the increase of the Attic revenues, the hiring out of slaves by the state for labour in the mines, after branding them to prevent their escape, the number of slaves being constantly increased by fresh purchases out of the gains of the enterprise.

Almost the whole system of Greek ideas up to the time of Aristotle is represented in his encyclopedic construction. Mathematical and astronomical science was largely developed at a later stage, but in the field of social studies no higher point was ever

attained by the Greeks than is reached in the writings of this great thinker. Both his gifts and his situation eminently favoured him in the treatment of these subjects. He combined in rare measure a capacity for keen observation with generalizing power, and sobriety of judgment with ardour for the public good. All that was original or significant in the political life of Hellas had run its course before his time or under his own eyes, and he had thus a large basis of varied experience on which to ground his conclusions. Standing outside the actual movement of contemporary public life, he occupied the position of thoughtful spectator and impartial judge. He could not indeed, for reasons already stated, any more than other Greek speculators, attain a fully normal attitude in these researches. Nor could he pass beyond the sphere of what is now called statical sociology; the idea of laws of the historical development of social phenomena he scarcely apprehended, except in some small degree in relation to the succession of political forms. But there is to be found in his writings a remarkable body of sound and valuable thoughts on the constitution and working of the social organism. The special notices of economic subjects are neither so numerous nor so detailed as we should desire. Like all the Greek thinkers, he recognizes but one doctrine of the state, under which ethics, politics proper, and economics take their place as departments, bearing to each other a very close relation, and having indeed their lines of demarcation from each other not very distinctly marked. When wealth comes under consideration, it is studied not as an end in itself, but with a view to the higher elements and ultimate aims of the collective life.

The origin of society he traces, not to economic necessities, but to natural social impulses in the human constitution. The nature of the social union, when thus established, being determined by the partly spontaneous partly systematic combination of diverse activities, he respects the independence of the latter whilst seeking to effect their convergence. He therefore opposes himself to the suppression of personal freedom and initiative, and the excessive subordination of the individual to the state, and rejects the community of property and wives proposed by Plato for his governing class. The principle of private property he regards as deeply rooted in man, and the evils which are alleged to result from the corresponding social ordinance he thinks ought really to be attributed either to the imperfections of our nature or to the vices of other public institutions. Community of goods must, in his view, tend to neglect of the common interest and to the disturbance of social harmony.

Of the several classes which provide for the different wants of the society, those who are occupied directly with its material needs—the immediate cultivators of the soil, the mechanics and artificers—are excluded from any share in the government of the state, as being without the necessary leisure and cultivation, and apt to be debased by the nature of their occupations. In a celebrated passage he propounds a theory of slavery, in which it is based on the universality of the relation between command and obedience, and on the natural division by which the ruling is marked off from the subject race. He regards the slave as having no independent will, but as an "animated tool" in the hands of his master; and in his subjection to such control, if only it be intelligent, Aristotle holds that the true wellbeing of the inferior as well as of the superior is to be found. This view, so shocking to our modern sentiment, is of course not personal to Aristotle; it is simply the theoretic presentation of the facts of Greek life, in which the maintenance of a body of citizens pursuing the higher culture and devoted to the tasks of war and government was founded on the systematic degradation of a wronged and despised class, excluded from all the higher offices of human beings and sacrificed to the maintenance of a special type of society.

The methods of economic acquisition are divided by Aristotle into two, one of which has for its aim the appropriation of natural products and their application to the material uses of the household; under this head come hunting, fishing, cattle-rearing, and agriculture. With this "natural economy," as it may be called, is, in some sense, contrasted the other method to which Aristotle gives the name of "chrematistic," in which an active exchange of products goes on, and money comes into operation as its medium and regulator. A certain measure of this "money economy," as it may be termed in opposition to the preceding and simpler form of industrial life, is accepted by Aristotle as a necessary extension of the latter, arising out of increased activity of intercourse, and satisfying real wants. But its development on the great scale, founded on the thirst for enjoyment and the unlimited desire of gain, he condemns as unworthy and corrupting. Though his views on this subject appear to be principally based on moral grounds, there are some indications of his having entertained the erroneous opinion held by the physiocrats of the 18th century, that agriculture alone (with the other branches of natural economy) is truly productive, whilst the other kinds of industry, which either modify the products of nature or distribute them by way of exchange, however convenient and useful they may be, make no addition to the wealth of the community.

He rightly regards money as altogether different from wealth,

illustrating the difference by the story of Midas. And he seems to have seen that money, though its use rests on a social convention, must be composed of a material possessing an independent value of its own. That his views on capital were indistinct appears from his famous argument against interest on loans, which is based on the idea that money is barren and cannot produce money.

Like the other Greek social philosophers, Aristotle recommends to the care of Governments the preservation of a due proportion between the extent of the civic territory and its population, and relies on pre-nuptial continence, late marriages, and the prevention or destruction of births for the due limitation of the number of citizens, the insufficiency of the latter being dangerous to the independence and its superabundance to the tranquillity and good order of the state.

*The Romans.*—Notwithstanding the eminently practical, realistic, and utilitarian character of the Romans, there was no energetic exercise of their powers in the economic field; they developed no large and many-sided system of production and exchange. Their historic mission was military and political, and the national energies were mainly devoted to the public service at home and in the field. To agriculture, indeed, much attention was given from the earliest times, and on it was founded the existence of the hardy population which won the first steps in the march to universal dominion. But in the course of their history the cultivation of the soil by a native yeomanry gave place to the introduction on a great scale of slave labourers, acquired by their foreign conquests; and for the small properties of the earlier period were substituted the vast estates—the *latifundia*—which, in the judgment of Pliny, were the ruin of Italy. The industrial arts and commerce (the latter, at least when not conducted on a great scale) they regarded as ignoble pursuits, unworthy of free citizens; and this feeling of contempt was not merely a prejudice of narrow or uninstructed minds, but was shared by Cicero (*De Off. i. 42*) and others among the most liberal spirits of the nation. As might be expected from the want of speculative originality among the Romans, there is little evidence of serious theoretic inquiry on economic subjects. Their ideas on these as on other social questions were for the most part borrowed from the Greek thinkers. Such traces of economic thought as do occur are to be found in (1) the philosophers, (2) the writers *de re rustica*, and (3) the jurists. It must, however, be admitted that many of the passages in these authors referred to by those who assert the claim of the Romans to a more prominent place in the history of the science often contain only obvious truths or vague generalities.

In the philosophers, whom Cicero, Seneca, and the elder Pliny sufficiently represent (the last indeed being rather a learned encyclopedist or polyhistor than a philosopher), we find a general consciousness of the decay of industry, the relaxation of morals, and the growing spirit of self-indulgence amongst their contemporaries, who are represented as deeply tainted with the imported vices of the conquered nations. This sentiment, both in these writers and in the poetry and miscellaneous literature of their times, is accompanied by a half-factitious enthusiasm for agriculture and an exaggerated estimate of country life and of early Roman habits, which are principally, no doubt, to be regarded as a form of protest against the evils of the present, and, from this point of view, remind us of the declamations of Rousseau in a not dissimilar age. But there is little of large or just thinking on the economic evils of the time and their proper remedies. Pliny, still further in the spirit of Rousseau, is of opinion that the introduction of gold as a medium of exchange was a thing to be deplored, and that the age of barter was preferable to that of money. He expresses views on the necessity of preventing the efflux of money similar to those of the modern mercantile school—views which Cicero also, though not so clearly, appears to have entertained. Cato, Varro, and Columella concern themselves more with the technical precepts of husbandry than with the general conditions of industrial success and social wellbeing. But the two last named have the great merit of having seen and proclaimed the superior value of free to slave labour, and Columella is convinced that to the use of the latter the decline of the agricultural economy of the Romans was in a great measure to be attributed. These three writers agree in the belief that it was chiefly by the revival and reform of agriculture that the threatening inroads of moral corruption could be

stayed, the old Roman virtues fostered, and the foundations of the commonwealth strengthened. Their attitude is thus similar to that of the French physiocrats invoking the improvement and zealous pursuit of agriculture alike against the material evils and the social degeneracy of their time. The question of the comparative merits of the large and small systems of cultivation appears to have been much discussed in the old Roman, as in the modern European world; Columella is a decided advocate of the *petite culture*. The jurists were led by the coincidence which sometimes takes place between their point of view and that of economic science to make certain classifications and establish some more or less refined distinctions which the modern economists have either adopted from them or used independently. They appear also (though this has been disputed, Neri and Carli maintaining the affirmative, Pagnini the negative) to have had correct notions of the nature of money as having necessarily a value of its own, determined by economic conditions, and therefore incapable of being impressed upon it by convention or arbitrarily altered by public authority. But in general we find in these writers, as might be expected, not so much the results of independent thought as documents illustrating the facts of Roman economic life, and the historical policy of the nation with respect to economic subjects. From the latter point of view they are of much interest; and by the information they supply as to the course of legislation relating to property generally, to sumptuary control, to the restrictions imposed on spendthrifts, to slavery, to the encouragement of population, and the like, they give us much clearer insight than we should otherwise possess into influences long potent in the history of Rome and of the Western world at large. But, as it is with the more limited field of systematic thought on political economy that we are here occupied, we cannot enter into these subjects. One matter, however, ought to be adverted to, because it was not only repeatedly dealt with by legislation, but is treated more or less fully by all Roman writers of note, namely, the interest on money loans. The rate was fixed by the laws of the Twelve Tables; but lending on interest was afterwards (B.C. 311) entirely prohibited by the *Lex Genucia*. In the legislation of Justinian, rates were sanctioned varying from four to eight per cent. according to the nature of the case, the latter being fixed as the ordinary mercantile rate, whilst compound interest was forbidden. The Roman theorists almost without exception disapprove of lending on interest altogether. Cato, as Cicero tells us, thought it as bad as murder (*"Quid fenerari? Quid hominem occidere?" De Off. ii. 15*); and Cicero, Seneca, Pliny, Columella all join in condemning it. It is not difficult to see how in early states of society the trade of money-lending becomes, and not unjustly, the object of popular odium; but that these writers, at a period when commercial enterprise had made such considerable progress, should continue to reprobate it argues very imperfect or confused ideas on the nature and functions of capital. It is probable that practice took little heed either of these speculative ideas or of legislation on the subject, which experience shows can always be easily evaded. The traffic in money seems to have gone on all through Roman history, and the rate to have fluctuated according to the condition of the market.

Looking back on the history of ancient economic speculation, we see that, as might be anticipated *a priori*, the results attained in that field by the Greek and Roman writers were very scanty. As Dühring has well remarked, the questions with which the science has to do were regarded by the ancient thinkers rather from their political than their properly economic side. This we have already pointed out with respect to their treatment of the subject of population, and the same may be seen in the case of the doctrine of the division of labour, with which Plato and Aristotle are in some degree occupied. They regard that principle as a basis of social classification, or use it in showing that society is founded on a spontaneous co-operation of diverse activities. From the strictly economic point of view, there are three important propositions which can be enunciated respecting that division:—(1) that its extension within any branch of production makes the products cheaper; (2) that it is limited by the extent of the market; and (3) that it can be carried farther in manufactures than in agriculture. But we shall look in vain for these propositions in the ancient writers; the first alone might be *inferred* from their discussions of the subject. It has been the tendency especially of German scholars to magnify unduly the extent and value of the contributions of antiquity to economic knowledge. The Greek and Roman authors ought certainly not to be omitted

in any account of the evolution of this branch of study. But it must be kept steadily in view that we find in them only first hints or rudiments of general economic truths, and that the science is essentially a modern one. We shall indeed see hereafter that it could not have attained its definitive constitution before our own time.

#### MIDDLE AGES.

The Middle Ages (400–1300 A.D.) form a period of great significance in the economic, as in the general, history of Europe. They represent a vast transition, in which the germs of a new world were deposited, but in which little was fully elaborated. There is scarcely anything in the later movement of European society which we do not find there, though as yet, for the most part, crude and undeveloped. The mediæval period was the object of contemptuous depreciation on the part of the liberal schools of the last century, principally because it contributed so little to literature. But there are things more important to mankind than literature; and the great men of the Middle Ages had enough to do in other fields to occupy their utmost energies. The development of the Catholic institutions and the gradual establishment and maintenance of a settled order after the dissolution of the Western empire absorbed the powers of the thinkers and practical men of several centuries. The first mediæval phase, from the commencement of the 5th century to the end of the 7th, was occupied with the painful and stormy struggle towards the foundation of the new ecclesiastical and civil system; three more centuries were filled with the work of its consolidation and defence against the assaults of nomad populations; only in the final phase, during the 11th, 12th, and 13th centuries, when the unity of the West was founded by the collective action against impending Moslem invasion, did it enjoy a sufficiently secure and stable existence to exhibit its essential character, and produce its noblest personal types. The elaboration of feudalism was, indeed, in progress during the whole period, showing itself in the decomposition of power and the hierarchical subordination of its several grades, the movement being only temporarily suspended during the second phase by the necessary defensive concentration under Charlemagne. But not before the first century of the last phase was the feudal system fully constituted. In like manner, only in the final phase could the effort of Catholicism after a universal discipline be carried out on the great scale—an effort for ever admirable, though necessarily on the whole unsuccessful.

No large or varied economic activity was possible under the ascendancy of feudalism. That organization, as has been abundantly shown by philosophical historians, was indispensable for the preservation of order and for public defence, and contributed important elements to general civilization. But, whilst recognizing it as opportune and relatively beneficent, we must not expect from it advantages inconsistent with its essential nature and historical office. The class which predominated in it was not sympathetic with industry, and held the handicrafts in contempt, except those subservient to war or rural sports. The whole practical life of the society was founded on territorial property; the wealth of the lord consisted in the produce of his lands and the dues paid to him in kind; this wealth was spent in supporting a body of retainers whose services were repaid by their maintenance. There could be little room for manufactures, and less for commerce; and agriculture was carried on with a view to the wants of the family, or at most of the immediate neighbourhood, not to those of a wider market. The economy of the period was therefore simple, and, in the absence of special motors from without, unprogressive.

In the latter portion of the Middle Ages several circumstances came into action which greatly modified these conditions. The crusades undoubtedly produced a powerful economic effect by transferring in many cases the possessions of the feudal chiefs to the industrious classes, whilst by bringing different nations and races into contact, by enlarging the horizon and widening the conceptions of the populations, as well as by affording a special stimulus to navigation, they tended to give a new activity to international trade. The independence of the towns and the rising importance of the burgher class supplied a counterpoise to the power of the land aristocracy; and the strength of these new social elements was increased by the corporate constitution given to the urban industries, the police of the towns being also founded on the trade guilds, as that of the country districts was on the feudal relations. The increasing demand of the towns for the products of agriculture gave to the prosecution of that art a more extended and speculative character; and this again led to improved methods of transport and communication. But the range of commercial enterprise continued everywhere narrow, except in some favoured centres, such as the Italian republics, in which, however, the growth of the normal habits of industrial life was impeded or perverted by military ambition, which was not, in the case of those communities, checked as it was elsewhere by the pressure of an aristocratic class.

Every great change of opinion on the destinies of man and the guiding principles of conduct must react on the sphere of material interests; and the Catholic religion had a powerful influence on the economic life of the Middle Ages. Christianity inculcates, perhaps, no more effectively than the older religions the special economic virtues of industry, thrift, fidelity to engagements, obedience to lawful authority; but it brought out more forcibly and presented more persistently the higher aims of life, and so produced a more elevated way of viewing the different social relations. It purified domestic life, a reform which has the most important economic results. It taught the doctrine of fundamental human equality, heightened the dignity of labour, and preached with quite a new emphasis the obligations of love, compassion, and forgiveness, and the claims of the poor. The constant presentation to the general mind and conscience of these ideas, the dogmatic bases of which were scarcely as yet assailed by scepticism, must have had a powerful effect in moralizing life. But to the influence of Christianity as a moral doctrine was added that of the church as an organization, charged with the application of that doctrine to men's daily transactions. Besides the teachings of the sacred books, there was a mass of ecclesiastical legislation providing specific prescriptions for the conduct of the faithful. And this legislation dealt with the economic as with other provinces of social activity. In the *Corpus Juris Canonici*, which condenses the result of centuries of study and effort, along with much else is set out what we may call the Catholic economic theory, if we understand by theory, not a reasoned explanation of phenomena, but a body of ideas leading to prescriptions for the guidance of conduct. Life is here looked at from the point of view of spiritual interests; the aim is to establish and maintain amongst men a true kingdom of God.

The canonists are friendly to the notion of a community of goods from the side of sentiment ("Dulcissima rerum possessio communis est"), though they regard the distinction of *meum* and *tuum* as an institution necessitated by the fallen state of man. In cases of need the public authority is justified in re-establishing *pro hac vice* the primitive community. The care of the poor is not a matter of free choice; the relief of their necessities is

*debitum legale*. *Avaritia* is idolatry; *cupiditas*, even when it does not grasp at what is another's, is the root of all evil, and ought to be not merely regulated but eradicated. Agriculture and handiwork are viewed as legitimate modes of earning food and clothing; but trade is regarded with disfavour, because it was held almost certainly to lead to fraud: of agriculture it was said, "Deo non displicet"; but of the merchant, "Deo placere non potest." The seller was bound to fix the price of his wares, not according to the market rate, as determined by supply and demand, but according to their intrinsic value (*justum pretium*). He must not conceal the faults of his merchandise, nor take advantage of the need or ignorance of the buyer to obtain from him more than the fair price. Interest on money is forbidden; the prohibition of usury is, indeed, as Roscher says, the centre of the whole canonistic system of economy, as well as the foundation of a great part of the ecclesiastical jurisdiction. The question whether a transaction was or was not usurious turning mainly on the intentions of the parties; the innocence or blameworthiness of dealings in which money was lent became rightfully a subject of determination for the church, either by her casuists or in her courts.

The foregoing principles point towards a noble ideal, but by their ascetic exaggeration they worked in some directions as an impediment to industrial progress. Thus, whilst, with the increase of production, a greater division of labour and a larger employment of borrowed capital naturally followed, the laws on usury tended to hinder this expansion. Hence they were undermined by various exceptions, or evaded by fictitious transactions. These laws were in fact dictated by, and adapted to, early conditions—to a state of society in which money loans were commonly sought either with a view to wasteful pleasures or for the relief of such urgent distress as ought rather to have been the object of Christian beneficence. But they were quite unsuited to a period in which capital was borrowed for ends useful to the public, for the extension of enterprise and the employment of labour. The absolute theological spirit in this, as in other instances, could not admit the modification in rules of conduct demanded by a new social situation; and vulgar good sense better understood what were the fundamental conditions of industrial life.

When the intellectual activity previously repressed by the more urgent claims of social preoccupations tended to revive towards the close of the mediæval period, the want of a rational appreciation of the whole of human affairs was felt, and was temporarily met by the adoption of the results of the best Greek speculation. Hence we find in the writings of St Thomas Aquinas the political and economic doctrines of Aristotle reproduced with a partial infusion of Christian elements. His adherence to his master's point of view is strikingly shown by the fact that he accepts (at least if he is the author of the *De Regimine Principum*) his theory of slavery, though by the action of the forces of his own time the last relics of that institution were being eliminated from European society.

This great change—the enfranchisement of the working classes—was the most important practical outcome of the Middle Ages. The first step in this movement was the transformation of slavery, properly so called, into serfdom. The latter is, by its nature, a transitory condition. The serf was bound to the soil, had fixed domestic relations, and participated in the religious life of the society; and the tendency of all his circumstances, as well as of the opinions and sentiments of the time, was in the direction of liberation. This issue was, indeed, not so speedily reached by the rural as by the urban workman. Already in the second phase serfdom is abolished in the cities and towns, whilst agricultural serfdom does not disappear

before the third. The latter revolution is attributed by Adam Smith to the operation of selfish interests, that of the proprietor on the one hand, who discovered the superior productiveness of cultivation by free tenants, and that of the sovereign on the other, who, jealous of the great lords, encouraged the encroachments of the vassals on their authority. But that the church deserves a share of the merit seems beyond doubt—moral impulses, as often happens, conspiring with political and economic motives. The serfs were treated best on the ecclesiastical estates, and the members of the priesthood, both by their doctrine and by their situation since the Northern conquests, were constituted patrons and guardians of the oppressed or subject classes.

Out of the liberation of the serfs rose the first lineaments of the hierarchical constitution of modern industry in the separation between the entrepreneurs and the workers. The personal enfranchisement of the latter, stimulating activity and developing initiative, led to accumulations, which were further promoted by the establishment of order and good government by the civic corporations which grew out of the enfranchisement. Thus an active capitalist class came into existence. It appeared first in commerce, the inhabitants of the trading cities importing expensive luxuries from foreign countries, or the improved manufactures of richer communities, for which the great proprietors gladly exchanged the raw produce of their lands. In performing the office of carriers, too, between different countries, these cities had an increasing field for commercial enterprise. At a later period, as Adam Smith has shown, commerce promoted the growth of manufactures, which were either produced for foreign sale, or made from foreign materials, or imitated from the work of foreign artificers. But the first important development of handicrafts in modern Europe belongs to the 14th and 15th centuries, and the rise of manufacturing entrepreneurs is not conspicuous within the Middle Ages properly so called. Agriculture, of course, lags behind; though the feudal lords tend to transform themselves into directors of agricultural enterprise, their habits and prejudices retard such a movement, and the advance of rural industry proceeds slowly. It does, however, proceed, partly by the stimulation arising from the desire to procure the finer objects of manufacture imported from abroad or produced by increased skill at home, partly by the expenditure on the land of capital amassed in the prosecution of urban industries.

Some of the trade corporations in the cities appear to have been of great antiquity; but it was in the 13th century that they rose to importance by being legally recognized and regulated. These corporations have been much too absolutely condemned by most of the economists, who insist on applying to the Middle Ages the ideas of the 18th and 19th centuries. They were, it is true, unfitted for modern times, and it was necessary that they should disappear; their existence indeed was quite unduly prolonged. But they were at first in several respects highly beneficial. They were a valuable rallying point for the new industrial forces, which were strengthened by the rise of the *esprit de corps* which they fostered. They improved technical skill by the precautions which were taken for the solidity and finished execution of the wares produced in each locality, and it was with a view to the advancement of the industrial arts that St. Louis undertook the better organization of the trades of Paris. The corporations also encouraged good moral habits through the sort of spontaneous surveillance which they exercised, and they tended to develop the social sentiment within the limits of each profession, in times when a larger public spirit could scarcely yet be looked for.

#### MODERN TIMES.

The close of the Middle Ages, as Comte has shown, must be placed at the end, not of the 15th, but of the 13th century. The modern period, which then began, is filled by a development exhibiting three successive phases, and issuing in the state of things which characterizes our own epoch. During the 14th and 15th centuries the Catholic-feudal system was breaking down by the mutual conflicts of its own official members, whilst the constituent elements of a new order were rising beneath it. On the practical side the antagonists matched against each other were the crown and the feudal chiefs; and these rival powers sought to strengthen themselves by forming alliances with the towns and the industrial forces they represented. The movements of this phase can scarcely be said to find an echo in any contemporary economic literature. In the second phase of the modern period, which opens with the beginning of the 16th century, the spontaneous collapse of the mediæval structure is followed by a series of systematic assaults which still further disorganize it. During this phase the central temporal power, which has made a great advance in stability and resources, lays hold of the rising elements of manufactures and commerce, and seeks, whilst satisfying the popular enthusiasm for their promotion, to use them for political ends, and make them subserve its own strength and splendour by furnishing the treasure necessary for military success. With this practical effort and the social tendencies on which it rests the mercantile school of political economy, which then obtains a spontaneous ascendancy, is in close relation. Whilst partially succeeding in the policy we have indicated, the European Governments yet on the whole necessarily fail, their origin and nature disqualifying them for the task of guiding the industrial movement; and the discredit of the spiritual power, with which most of them are confederate, further weakens and undermines them. In the last phase, which coincides approximately with the 18th century, the tendency to a completely new system, both temporal and spiritual, becomes decisively pronounced, first in the philosophy and general literature of the period, and then in the great French explosion. The universal critical doctrine, which had been announced by the Protestantism of the previous phase, and systematized in England towards the close of that phase, is propagated and popularized, especially by French writers. The spirit of individualism inherent in the doctrine was eminently adapted to the wants of the time, and the general favour with which the dogmas of the social contract and *laissez faire* were received indicated a just sentiment of the conditions proper to the contemporary situation of European societies. So long as a new coherent system of thought and life could not be introduced, what was to be desired was a large and active development of personal energy under no further control of the old social powers than would suffice to prevent anarchy. Governments were therefore rightly called on to abandon any effective direction of the social movement, and, as far as possible, to restrict their intervention to the maintenance of material order. This policy was, from its nature, of temporary application only; but the negative school, according to its ordinary spirit, erected what was merely a transitory and exceptional necessity into a permanent and normal law. The unanimous European movement towards the liberation of effort, which sometimes rose to the height of a public passion, had various sides, corresponding to the different aspects of thought and life; and of the economic side the French physiocrats were the first theoretic representatives on the large scale, though the office they undertook was, both in its destructive and organic provinces, more thoroughly and effectively done

by Adam Smith, who must be regarded as continuing and completing their work.

It must be admitted that with the whole modern movement serious moral evils were almost necessarily connected. The general discipline which the Middle Ages had sought to institute and had partially succeeded in establishing, though on precarious bases, having broken down, the sentiment of duty was weakened along with the spirit of *ensemble* which is its natural ally, and individualism in doctrine tended to encourage egoism in action. In the economic field this result is specially conspicuous. National selfishness and private cupidity increasingly dominate; and the higher and lower industrial classes tend to separation and even to mutual hostility. The new elements—science and industry—which were gradually acquiring ascendancy bore indeed in their bosom an ultimate discipline more efficacious and stable than that which had been dissolved; but the final synthesis was long too remote, and too indeterminate in its nature, to be seen through the dispersive and seemingly incoherent growth of those elements. Now, however, that synthesis is becoming appreciable; and it is the effort towards it, and towards the practical system to be founded on it, that gives its peculiar character to the period in which we live. And to this spontaneous *nisus* of society corresponds, as we shall see, a new form of economic doctrine, in which it tends to be absorbed into general sociology and subordinated to morals.

It will be the object of the following pages to verify and illustrate in detail the scheme here broadly indicated, and to point out the manner in which the respective features of the several successive modern phases find their counterpart and reflexion in the historical development of economic speculation.

#### FIRST MODERN PHASE.

The first phase was marked, on the one hand, by the spontaneous decomposition of the mediæval system, and, on the other, by the rise of several important elements of the new order. The spiritual power became less apt as well as less able to fulfil its moral office, and the social movement was more and more left to the irregular impulses of individual energy, often enlisted in the service of ambition and cupidity. Strong Governments were formed, which served to maintain material order amidst the growing intellectual and moral disorder. The universal admission of the commons as an element in the political system showed the growing strength of the industrial forces, as did also in another way the insurrections of the working classes. The decisive prevalence of peaceful activity was indicated by the rise of the institution of paid armies—at first temporary, afterwards permanent—which prevented the interruption or distraction of labour by devoting a determinate minority of the population to martial operations and exercises. Manufactures became increasingly important; and in this branch of industry the distinction between the entrepreneur and the workers was first firmly established, whilst fixed relations between these were made possible by the restriction of military training and service to a special profession. Navigation was facilitated by the use of the mariner's compass. The art of printing showed how the intellectual movement and the industrial development were destined to be brought into relation with each other and to work towards common ends. Public credit rose in Florence, Venice, and Genoa long before Holland and England attained any great financial importance. Just at the close of the phase, the discovery of America and of the new route to the East, whilst revolutionizing the course of trade, prepared the way for the establishment of colonies, which contributed powerfully to the growing preponderance

of industrial life, and pointed to its ultimate universality. It is doubtless due to the equivocal nature of the stage, standing between the mediæval and the fully characterized modern period, that on the theoretic side we find nothing corresponding to this marvellous practical ferment and expansion. The general political doctrine of Aquinas was retained, with merely subordinate modifications. The only special economic question which seems to have received particular attention was that of the nature and functions of money, the importance of which began to be felt as payments in service or in kind were discontinued, and regular systems of taxation began to be introduced.

Roscher, and after him Wolowski, have called attention to Nicole Oresme, who died bishop of Lisieux in 1382. Roscher pronounces him a great economist. His *Tractatus de Origine, Natura, Jure, et Mutationibus Monetarium* (reprinted by Wolowski, 1864) contains a theory of money which is almost entirely correct according to the views of the 19th century, and is stated with such brevity, clearness, and simplicity of language as, more than anything else, show the work to be from the hand of a master.

#### SECOND MODERN PHASE: MERCANTILE SYSTEM.

Throughout the first modern phase the rise of the new social forces had been essentially spontaneous; in the second they became the object of systematic encouragement on the part of Governments, which, now that the financial methods of the Middle Ages no longer sufficed, could not further their military and political ends by any other means than increased taxation, implying augmented wealth of the community. Industry thus became a permanent interest of European Governments, and even tended to become the principal object of their policy. In natural harmony with this state of facts, the mercantile system arose and grew, attaining its highest development about the middle of the 17th century.

The mercantile doctrine, stated in its most extreme form, makes wealth and money identical, and regards it therefore as the great object of a community so to conduct its dealings with other nations as to attract to itself the largest possible share of the precious metals. Each country must seek to export the utmost possible quantity of its own manufactures, and to import as little as possible of those of other countries, receiving the difference of the two values in gold and silver. This difference is called the balance of trade, and the balance is favourable when more money is received than is paid. Governments must resort to all available expedients—prohibition of, or high duties on, the importation of foreign wares, bounties on the export of home manufactures, restrictions on the export of the precious metals—for the purpose of securing such a balance.

But this statement of the doctrine, though current in the text books, does not represent correctly the views of all who must be classed as belonging to the mercantile school. Many of the members of that school were much too clear-sighted to entertain the belief, which the modern student feels difficulty in supposing any class of thinkers to have professed, that wealth consists exclusively of gold and silver. The mercantilists may be best described, as Roscher has remarked, not by any definite economic theorem which they held in common, but by a set of theoretic tendencies, commonly found in combination, though severally prevailing in different degrees in different minds. These tendencies may be enumerated as follows:—(1) towards overestimating the importance of possessing a large amount of the precious metals; (2) towards an undue exaltation (a) of foreign trade over domestic, and (b) of the industry which works up materials over that which provides them; (3) towards attaching too high a value to a dense population as an element of national strength; and (4) towards invoking the action of the state

in furthering artificially the attainment of the several ends thus proposed as desirable.

If we consider the contemporary position of affairs in western Europe, we shall have no difficulty in understanding how these tendencies would inevitably arise. The discoveries in the New World had led to a large development of the European currencies. The old feudal economy, founded principally on dealings in kind, had given way before the new "money economy," and the dimensions of the latter were everywhere expanding. Circulation was becoming more rapid, distant communications more frequent, city life and movable property more important. The mercantilists were impressed by the fact that money is wealth *sui generis*, that it is at all times in universal demand, and that it puts into the hands of its possessor the power of acquiring all other commodities. The period, again, was marked by the formation of great states, with powerful Governments at their head. These Governments required men and money for the maintenance of permanent armies, which, especially for the religious and Italian wars, were kept up on a great scale. Court expenses, too, were more lavish than ever before, and a larger number of civil officials was employed. The royal domains and dues were insufficient to meet these requirements, and taxation grew with the demands of the monarchies. Statesmen saw that for their own political ends industry must flourish. But manufactures make possible a denser population and a higher total value of exports than agriculture; they open a less limited and more promptly extensible field to enterprise. Hence they became the object of special Governmental favour and patronage, whilst agriculture fell comparatively into the background. The growth of manufactures reacted on commerce, to which a new and mighty arena had been opened by the establishment of colonies. These were viewed simply as estates to be worked for the advantage of the mother countries, and the aim of statesmen was to make the colonial trade a new source of public revenue. Each nation, as a whole, working for its own power, and the greater ones for predominance, they entered into a competitive struggle in the economic no less than in the political field, success in the former being indeed, by the rulers, regarded as instrumental to pre-eminence in the latter. A national economic interest came to exist, of which the Government made itself the representative head. States became a sort of artificial hothouses for the rearing of urban industries. Production was subjected to systematic regulation with the object of securing the goodness and cheapness of the exported articles, and so maintaining the place of the nation in foreign markets. The industrial control was exercised, in part directly by the state, but largely also through privileged corporations and trading companies. High duties on imports were resorted to, at first perhaps mainly for revenue, but afterwards in the interest of national production. Commercial treaties were a principal object of diplomacy, the end in view being to exclude the competition of other nations in foreign markets, whilst in the home market as little room as possible was given for the introduction of anything but raw materials from abroad. The colonies were prohibited from trading with other European nations than the parent country, to which they supplied either the precious metals or raw produce purchased with home manufactures. It is evident that what is known as the mercantile doctrine was essentially the theoretic counterpart of the practical activities of the time, and that nations and Governments were led to it, not by any form of scientific thought, but by the force of outward circumstance, and the observation of facts which lay on the surface.

And yet, if we regard the question from the highest

point of view of philosophic history, we must pronounce the universal enthusiasm of this second modern phase for manufactures and commerce to have been essentially just, as leading the nations into the main avenues of general social development. If the thought of the period, instead of being impelled by contemporary circumstances, could have been guided by sociological prevision, it must have entered with zeal upon the same path which it empirically selected. The organization of agricultural industry could not at that period make any marked progress, for the direction of its operations was still in the hands of the feudal class, which could not in general really learn the habits of industrial life, or place itself in sufficient harmony with the workers on its domains. The industry of the towns had to precede that of the country, and the latter had to be developed mainly through the indirect action of the former. And it is plain that it was in the life of the manufacturing proletariat, whose labours are necessarily the most continuous and the most social, that a systematic discipline could at a later period be first applied, to be afterwards extended to the rural populations.

That the efforts of Governments for the furtherance of manufactures and commerce were really effective towards that end is admitted by Adam Smith, and cannot reasonably be doubted, though free trade doctrinaires have often denied it. Technical skill must have been promoted by their encouragements; whilst new forms of national production were fostered by attracting workmen from other countries, and by lightening the burden of taxation on struggling industries. Communication and transport by land and sea were more rapidly improved with a view to facilitate traffic; and, not the least important effect, the social dignity of the industrial professions was enhanced relatively to that of the classes before exclusively dominant.

It has often been asked to whom the foundation of the mercantile system, in the region whether of thought or of practice, is to be attributed. But the question admits of no absolute answer. That mode of conceiving economic facts arises spontaneously in unscientific minds, and ideas suggested by it are to be found in the Greek and Latin writers. The policy which it dictates was, as we have shown, inspired by the situation of the European nations at the opening of the modern period. Such a policy had been already in some degree practised in the 14th and 15th centuries, thus preceding any formal exposition or defence of its speculative basis. At the commencement of the 16th century it began to exercise a widely extended influence. Charles V. adopted it, and his example contributed much to its predominance. Henry VIII. and Elizabeth conformed their measures to it. The leading states soon entered on a universal competition, in which each power brought into play all its political and financial resources for the purpose of securing to itself manufacturing and commercial preponderance. Through almost the whole of the 17th century the prize, so far as commerce was concerned, remained in the possession of Holland, Italy having lost her former ascendancy by the opening of the new maritime routes, and Spain and Germany being depressed by protracted wars and internal dissensions. The admiring envy of Holland felt by English politicians and economists appears in such writers as Raleigh, Mun, Child, and Temple; and how strongly the same spectacle acted on French policy is shown by a well-known letter of Colbert to M. de Pomponne, ambassador to the Dutch States. Cromwell, by his Navigation Act, which destroyed the carrying trade of Holland and founded the English empire of the sea, and Colbert, by his whole economic policy, domestic and international, were the chief practical representatives of the mercantile system. From the latter great statesman the Italian

publicist Mengotti gave to that system the name of *Colbertismo*; but it would be an error to consider the French minister as having absolutely accepted its dogmas. He regarded his measures as temporary only, and spoke of protective duties as crutches by the help of which manufacturers might learn to walk and then throw them away. The policy of exclusions had been previously pursued by Sully, partly with a view to the accumulation of a royal treasure, but chiefly from his special enthusiasm for agriculture, and his dislike of the introduction of foreign luxuries as detrimental to the national character. Colbert's tariff of 1664 not merely simplified but considerably reduced the existing duties; the tariff of 1667 indeed increased them, but that was really a political measure directed against the Dutch. It seems certain that France owed in a large measure to his policy the vast development of trade and manufactures which so much impressed the imagination of contemporary Europe, and of which we hear so much from English writers of the time of Petty. But this policy had also undeniably its dark side. Industry was forced by such systematic regulation to follow invariable courses, instead of adapting itself to changing tastes and popular demand. Nor was it free to simplify the processes of production, or to introduce increased division of labour and improved appliances. Spontaneity, initiation, and invention were repressed or discouraged, and thus ulterior sacrificed in a great measure to immediate results. The more enlightened statesmen, and Colbert in particular, endeavoured, it is true, to minimize these disadvantages by procuring, often at great expense, and communicating to the trades through inspectors nominated by the Government, information respecting improved processes employed elsewhere in the several arts; but this, though in some degree a real, was certainly on the whole, and in the long run, an insufficient compensation.

We must not expect from the writers of this stage any exposition of political economy as a whole; the publications which appeared were for the most part evoked by special exigencies, and related to particular questions, usually of a practical kind, which arose out of the great movements of the time. They were in fact of the nature of counsels to the Governments of states, pointing out how best they might develop the productive powers at their disposal and increase the resources of their respective countries. They are conceived (as List claims for them) strictly in the spirit of *national* economy; and cosmopolitanism is essentially foreign to them. On these monographs the mercantile theory sometimes had little influence, the problems discussed not involving its tenets. But it must in most cases be taken to be the scheme of fundamental doctrine (so far as it was ever entitled to such a description) which in the last resort underlies the writer's conclusions.

The rise of prices following on the discovery of the American mines was one of the subjects which first attracted the attention of theorists. This rise brought about a great and gradually increasing disturbance of existing economic relations, and so produced much perplexity and anxiety, which were all the more felt because the cause of the change was not understood. To this was added the loss and inconvenience arising from the debasement of the currency often resorted to by sovereigns as well as by republican states. Italy suffered most from this latter abuse, which was multiplied by her political divisions. It was this evil which called forth the work of Count Gasparo Scaruffi (*Discorso sopra le monete e della vera proporzione fra l'oro e l'argento*, 1582). In this he put forward the bold idea of a universal money, everywhere identical in size, shape, composition, and designation. The project was, of course, premature, and was not adopted even by the Italian princes to whom the author specially appealed; but the reform is one which, doubtless, the future will see realized. Gian Donato Turbolo, master of the Neapolitan mint, in his *Discorsi e Relazioni*, 1629, protested against any tampering with the currency. Another treatise relating to the subject of money was that of the Florentine

Bernardo Davanzati, otherwise known as the able translator of Tacitus, *Lezioni delle Monete*, 1588. It is a slight and somewhat superficial production, only remarkable as written with correctness and elegance of style.

A French writer who dealt with the question of money, but from Bodin a different point of view, was Jean Bodin. In his *Réponse aux paradoxes de M. Malestroit touchant l'encherissement de toutes les choses et des monnaies*, 1568, and in his *Discours sur le relèvement et diminution des monnaies*, 1578, he showed a more rational appreciation than many of his contemporaries of the causes of the revolution in prices, and the relation of the variations in money to the market values of wares in general as well as to the wages of labour. He saw that the amount of money in circulation did not constitute the wealth of the community, and that the prohibition of the export of the precious metals was useless, because rendered inoperative by the necessities of trade. Bodin is no inconsiderable figure in the literary history of the epoch, and did not confine his attention to economic problems; in his *Six livres de la République*, about 1576, he studies the general conditions of the prosperity and stability of states. In harmony with the conditions of his age, he approves of absolute Governments as the most competent to ensure the security and wellbeing of their subjects. He enters into an elaborate defence of individual property against Plato and More, rather perhaps because the scheme of his work required the treatment of that theme than because it was practically urgent in his day, when the excesses of the Anabaptists had produced a strong feeling against communistic doctrines. He is under the general influence of the mercantilist views, and approves of energetic Governmental interference in industrial matters, of high taxes on foreign manufactures and low duties on raw materials and articles of food, and attaches great importance to a dense population. But he is not a blind follower of the system; he wishes for unlimited freedom of trade in many cases; and he is in advance of his more eminent contemporary Montaigne in perceiving that the gain of one nation is not necessarily the loss of another. To the public finances, which he calls the sinews of the state, he devotes much attention, and insists on the duties of the Government in respect to the right adjustment of taxation. In general he deserves the praise of steadily keeping in view the higher aims and interests of society in connexion with the regulation and development of its material life.

Correct views as to the cause of the general rise of prices are also set forth by the English writer, W. S. (William Stafford), in his *Briefe Conception of English Policy*, published in 1581, and dedicated to Queen Elizabeth. It is in the form of a dialogue, and is written with liveliness and spirit. The author seems to have been acquainted with the writings of Bodin. He has just ideas as to the nature of money, and fully understands the evils arising from a debased coinage. He describes in detail the way in which the several interests in the country had been affected by such debasement in previous reigns, as well as by the change in the value of the precious metals. The great popular grievance of his day, the conversion of arable land into pasture, he attributes chiefly to the restrictions on the export of corn, which he desires to see abolished. But in regard to manufactures he is at the same point of view with the later mercantilists, and proposes the exclusion of all foreign wares which might as well be provided at home, and the prohibition of the export of raw materials intended to be worked up abroad.

Out of the question of money, too, arose the first remarkable All-German production on political economy which had an original pamphlet national character and addressed the public in the native tongue. Duke George of the Ernestine Saxon line was inclined (1530) to introduce a debasement of the currency. A pamphlet, *Geneine Symmen von der Münze*, was published in opposition to this proceeding, under the auspices of the Albertine branch, whose policy was sounder in the economic sphere no less than in that of ecclesiastical affairs. A reply appeared justifying the Ernestine project. This was followed by a rejoinder from the Albertine side. The Ernestine pamphlet is described by Roscher as ill-written, obscure, inflated, and, as might be expected from the thesis it maintained, sophistical. But it is interesting as a statement of the fundamental principles of the currency. It contains more than one hundred years before the publication of Mun's book, and forty-six before that of Bodin's *Six livres de la République*. The Albertine tracts, according to Roscher, exhibit such sound views of the conditions and evidences of national wealth, of the nature of money and trade, and of the rights and duties of Governments in relation to economic action, that he regards the unknown author as entitled to a place beside Raleigh and the other English "colonial-theorists" of the end of the 16th and beginning of the 17th century.

In connexion with the same subject of money we meet the great Copernicus. His treatise *De monetae emendanda ratione*, 1526 (first printed in 1816), was written by order of King Sigismund I., and is an exposition of the principles on which it was proposed to reform the currency of the Prussian provinces of Poland. It advocates unity of the monetary system throughout the entire

state, with strict integrity in the quality of the coin, and the charge of a seigniorage sufficient to cover the expenses of minting.

Antonio Serra is regarded by some as the creator of modern political economy. He was a native of Cosenza in Calabria. His *Breve Trattato delle cause che possono fare abbandare il regno d'oro e d'argento dove non sono miniere*, 1613, was written during his imprisonment, which is believed to have been due to his having taken part in the conspiracy of Campanella for the liberation of Naples from the Spanish yoke and the establishment of a republican government. This work, long overlooked, was brought into notice in the following century by Galiani and others. Its title alone would sufficiently indicate that the author had adopted the principles of the mercantile system, and in fact in this treatise the essential doctrines of that system are expounded in a relatively formal and conservative manner. He strongly insists on the superiority of manufactures over agriculture as a source of national wealth, and uses in support of this view the prosperity of Genoa, Florence, and Venice, as contrasted with the depressed condition of Naples. With larger insight than many of the mercantilists exhibit, he points out the importance towards the acquisition of wealth, not alone of favourable external conditions, but of energetic character and industrious habits in a population, as well as of a stable government and a good administration of the laws.

The first systematic treatise on our science which proceeded from a French author was the *Traité de l'Economie Politique*, published by Montesquieu de Waverille in 1615. The use of the title, says Roscher, now for the first time given to the science, was in itself an important service, since even Bacon understood by "Economic" only the theory of domestic management. The general tendencies and aims of the period are seen in the fact that this treatise, notwithstanding the comprehensive name it bears, does not deal with agriculture at all, but only with the mercantile arts, navigation, commerce, and public finance. The author is filled with the then dominant enthusiasm for foreign trade and colonies. He advocates the control by princes of the industry of their subjects, and condemns the too great freedom, which, in his opinion to their own detriment, the Governments of Spain, Portugal, and Holland had given to trade. His book may be regarded as a formal exposition of the principles of the mercantile system for the use of Frenchmen.

A similar office was performed in England by Thomas Mun. In his two works *A Discourse of Trade from England unto the East Indies*, 2d ed., 1621, and especially in *England's Treasure by Foreign Trade*, 1664 (posthumous), we have for the first time a clear and systematic statement of the theory of the balance of trade, as well as of the means by which, according to the author's view, a favourable balance could be secured for England. The great object of the economic policy of a state, according to him, should be so to manage its export of manufactures, its direct and carrying trade, and its customs duties as to attract to itself money from abroad. He was, however, opposed to the prohibition of the export of the precious metals in exchange for foreign wares, but on the ground, fully according with his general principles, that these wares might afterwards be re-exported and might then bring back more treasure than had been originally expended in their purchase; the first export of money might be, as he said, the seed-time, of which the ultimate receipt of a larger amount would be the harvest. He saw, too, that it is inexpedient to have too much money circulating in a country, as this enhances the prices of commodities, and so makes them less saleable to foreigners, but he is favourable to the formation and maintenance of a state treasury.<sup>1</sup>

One of the most remarkable of the moderate mercantilists was Sir Josiah Child (*Brief Observations concerning Trade and the Interest of Money*, 1662, and *A New Discourse of Trade*, 1663 and 1690). He was one of those who held up Holland as a model for the imitation of his fellow-countrymen. He is strongly impressed with the importance for national wealth and wellbeing of a low rate of interest, which he says is to commerce and agriculture what the soil is to the body, and which he held to be the "great enemy" of all the other enemies of the riches of the Dutch people.<sup>2</sup> Instead of regarding such low rate as dependent on determinate conditions, which should be allowed to evolve themselves spontaneously, he thinks it should be created and maintained by public authority. Child, whilst adhering to the doctrine of the balance of trade, observes that a people cannot always sell to foreigners without ever buying from them, and denies that the export of the precious metals is necessarily detrimental. He has the ordinary mercantilist partiality for a numerous population. He advocates the reservation by the mother country of the sole right of trade with her colonies, and under certain limitations, the formation of privileged trading companies. As to the Navigation Act, he takes up a position not

unlike that afterwards occupied by Adam Smith, regarding that measure much more favourably from the political than from the economic point of view. It will be seen that he is somewhat eclectic in his opinions; but he cannot properly be regarded, though some have attributed to him that character, as a proponent of the free-trade school of the 18th century.

Two other ecclesies may be here mentioned, in whom his views are mingled with mercantilist prejudices—Sir William Temple and Charles Davenant. The former in his *Observations upon the United Provinces of the Netherlands*, 1672, and his *Essay on the Trade of Ireland*, 1673, has many excellent remarks on fundamental economic principles, as on the functions of labour and of saving in the production of national wealth; but he is infected with the errors of the theory of the balance of trade. He follows the lead of Raleigh and Child in urging his fellow-countrymen to imitate the example of the Dutch in their economic policy—a vice which in his case was founded on his observations during a lengthened residence in Holland as ambassador to the States. Davenant, in his *Essay on the East-India Trade*, 1694-95, *Essay Davenant on the Private Ways of making the People Gainers in the Balance of Trade*, 1695, &c., also takes up an eclectic position, combining some correct views on wealth and money with mercantilist notions on trade, and recommending Governmental restrictions on colonial commerce as strongly as he advocates freedom of exchange at home.

Whilst the mercantile system represented the prevalent form of economic thought in the 17th century, and was alone dominant in the region of practical statesmanship, there was growing up, side by side with it, a body of opinion, different and indeed hostile in character, which was destined ultimately to drive it from the field. The new ideas were first developed in England, though it was in France that in the following century they took hold of the public mind, and became a power in politics. That they should first show themselves here, and afterwards be extended, applied, and propagated throughout Europe by French writers, belongs to the order of things according to which the general negative doctrine in morals and politics, undoubtedly of English origin, found its chief home in France, and was thence diffused in widening circles through the civilized world. In England this movement of economic thought took the shape mainly of individual criticism of the prevalent doctrines, founded on a truer analysis of facts and conceptions; in France it was permeated with a powerful social sentiment, furnished the creed of a party, and inspired a protest against institutions and an urgent demand for practical reform.

Regarded from the theoretic side, the characteristic features of the new direction were the following. The view of at least the extreme mercantilists that national wealth depends on the accumulation of the precious metals is proved to be false, and the gifts of nature and the labour of man are shown to be its real sources. The exaggerated estimate of the importance of foreign commerce is reduced, and attention is once more turned to agriculture and the conditions of its successful prosecution. On the side of practical policy, a so-called favourable balance of trade is seen not to be the true object of a nation's or a statesman's efforts, but the procuring for the whole population in the fullest measure the enjoyment of the necessities and conveniences of life. And—what more than anything else contrasts the new system with the old—the elaborate apparatus of prohibitions, protective duties, bounties, monopolies, and privileged corporations, which the European Governments had created in the supposed interests of manufactures and trade, is denounced or deprecated as more an impediment than a furtherance, and the freedom of industry is insisted on as the one thing needful. This circle of ideas, of course, emerges only gradually, and its earliest representatives in economic literature in general apprehend it imperfectly and advocate it with reserve; but it rises steadily in importance, being more and more favoured by the highest minds, and finding an increasing body of supporters amongst the intelligent public.

<sup>1</sup> Writers of less importance who followed the same doctrine were Sir Thomas Cooper (*A Treatise upon the Right East of Wares*, 1670, and *Charles' Emancipation*, 1671); Sir Josiah Child (*Discourse of Trade*, 1673); G. Milnes (*Grounds of the Law of Trade*, 1675); E. Maresca (*Grounds of Commerce*, 1675); Samuel Parnley (*Essays in Trade and Improvement*, 1673 and 1675); and John P. Gordon (*Essay on the Trade and Improvement in the West Indies*, 1675).

Hobbes. Some occasional traits of an economic scheme in harmony with these new tendencies are to be found in the *De Cive* and *Leviathan* of Hobbes. But the efficacy of that great thinker lay rather in the general philosophic field; and by systematizing, for the first time, the whole negative doctrine, he gave a powerful impulse towards the demolition of the existing social order, which was destined, as we shall see, to have momentous consequences in the economic no less than in the strictly political department of things.

A writer of no such extended range, but of much sagacity and good sense, was Sir WILLIAM PETTY (q.v.), author of a number of pieces containing germs of a sound economic doctrine. A leading thought in his writings is that "labour is the father and active principle of wealth, lands are the mother." He divides a population into two classes, the productive and the unproductive, according as they are or are not occupied in producing useful material things. The value of any commodity depends, he says, anticipating Ricardo, on the amount of labour necessary for its production. He is desirous of obtaining a universal measure of value, and chooses as his unit the average food of the cheapest kind required for a man's daily sustenance. He understands the nature of the rent of land as the excess of price over the cost of production. He disapproves of the attempt to fix by authority a maximum rate of interest, and is generally opposed to Governmental interference with the course of industry. He sees that a country requires for its exchanges a definite quantity of money and may have too much of it, and condemns the prohibition of its exportation. He holds that one only of the precious metals must be the foundation of the currency, the other circulating as an ordinary article of merchandise. Petty's name is specially associated with the progress of statistics, with which he was much occupied, and which he called by the name of political arithmetic. Relying on the results of such inquiries, he set himself strongly against the opinion which had been advanced by the author of *Brillannia Lau-guens* (1680), Fortrey, Roger Coke, and other writers, that the prosperity of England was on the decline.

The most thorough-going and emphatic assertion of the free-trade doctrine against the system of prohibitions which had gained strength by the Revolution was contained in Sir Dudley North's *Discourses upon Trade*, 1691. He shows that wealth may exist independently of gold or silver, its source being human industry, applied either to the cultivation of the soil or to manufactures. The precious metals, however, are one element of national wealth, and perform highly important offices. Money may exist in excess, as well as in defect, in a country; and the quantity of it required for the purposes of trade will vary with circumstances; its ebb and flow will regulate themselves spontaneously. It is a mistake to suppose that stagnation of trade arises from want of money; it must arise either from a glut of the home market, or from a disturbance of foreign commerce, or from diminished consumption caused by poverty. The export of money in the course of traffic, instead of diminishing, increases the national wealth, trade being only an exchange of superfluities. Nations are related to the world just in the same way as cities to the state or as families to the city. North emphasizes more than his predecessors the value of the home trade. With respect to the interest of capital, he maintains that it depends, like the price of any commodity, on the proportion of demand and supply, and that a low rate is a result of the relative increase of capital, and cannot be brought about by arbitrary regulations, as had been proposed by Child and others. In arguing the question of free trade, he urges that individuals often take their private interest as the measure of good and evil, and would for its sake deprive others from their equal right of buying and selling, but that every advantage given to one interest or branch of trade over another is injurious to the public. No trade is unprofitable to the public; if it were, it would be given up; when trades thrive, so does the public, of which they form a part. Prices must determine themselves, and cannot be fixed by law; and all forcible interference with them does harm instead of good. No people can become rich by state regulations,—only by peace, industry, freedom, and unimpeded economic activity. It will be seen how closely North's view of things approaches to that embodied some eighty years later in Adam Smith's great work.

Locke. Locke is represented by Roscher as, along with Petty and North, making up the "triumvirate" of eminent British economists of this period who laid the foundations of a new and more rational doctrine than that of the mercantilists. But this view of his claims seems capable of being accepted only with considerable deductions. His specially economic writings are *Considerations of the lowering of Interest and raising the value of Money*, 1691, and *Further Considerations*, 1693. Though Leibnitz declared with respect to these treatises that nothing more solid or intelligent could be said on their subject, it is difficult to adopt that verdict. Locke's spirit of sober observation and patient analysis led him indeed to some just conclusions; and he is entitled to the credit of having energetically resisted the debasement of the currency, which was then recommended by some who were held to be eminent practical authorities. But he falls into errors

which show that he had not by any means completely emancipated himself from the ideas of the mercantile system. He attaches far too much importance to money as such. He says expressly that riches consist in a plenty of gold and silver, that is, as he explains, in having more in proportion of those metals than the rest of the world or than our neighbours. "In a country not furnished with mines, there are but two ways of growing rich, either conquest or commerce." Hence he accepts the doctrine of the balance of trade. He shows that the rate of interest can no more be fixed by law than the rent of houses or the hire of ships, and opposes Child's demand for legislative interference with it. But he erroneously attributed the fall of the rate which had taken place generally in Europe to the increase of the quantity of gold and silver by the discovery of the American mines. He sets too absolute a value on a numerous population, in this point agreeing with Petty. On wages he observes that the rate must be such as to cover the indispensable wants of the labourer; when the price of subsistence rises, wages must rise in a like ratio, or the working population must come on the poor-rates. The fall of the rent of land he regards as a sure sign of the decline of national wealth. "Taxes, however contrived, and out of whose hands soever immediately taken, do, in a country where their great fund is in land, for the most part terminate upon land." In this last proposition we see a foreshadowing of the *impitoyable* unique of the physiocrats. Whatever may have been Locke's direct economic services, his principal importance, like that of Hobbes, lies in his general philosophic and political principles, which powerfully affected French and indeed European thought, exciting a spirit of opposition to arbitrary power, and laying the foundation of the doctrine developed in the *Contrat Social*.<sup>1</sup>

### THIRD MODERN PHASE: SYSTEM OF NATURAL LIBERTY.

Both in England and France the ruling powers had already begun to be alarmed by the subversive tendencies which appeared inherent in the modern movement, and took up in consequence an attitude of resistance. Reaction became triumphant in France during the latter half of the reign of Louis XIV. under the disastrous influence of Madame de Maintenon. In England, after the transaction of 1688, by which the government was consolidated on the double basis of aristocratic power and official orthodoxy, the state policy became not so much retrograde as stationary, industrial conquest being put forward to satisfy the middle class and wean it from the pursuit of a social renovation. In both countries there was for some time a noticeable check in the intellectual development, and Roscher and others have observed that, in economic studies particularly, the first three decades of the 18th century were a period of general stagnation, eclectic for the most part taking the place of originality. The movement was, however, soon to be resumed, but with an altered and more formidable character. The negative doctrine, which had risen and taken a definite form in England, was diffused and popularized in France, where it became evident, even before the decisive explosion, that the only possible issue lay in a radical social transformation. The partial schools of Voltaire and Rousseau in different ways led up to a violent crisis, whilst taking little thought of the conditions of a system which could replace the old; but the more complete and organic school, of which Diderot is the best representative, looked through freedom to reorganization. Its constructive aim is shown by the design of the *Encyclopédie*,—a project, however, which could have only a temporary success, because no real synthesis was forthcoming, and this joint production of minds often divergent could possess no more than an external unity. It was with this great school that the physiocrats were specially connected; and, in common with its other members, whilst

<sup>1</sup> Minor English writers who followed the new economic direction were Lewis Roberts, *Treasure of Traffick*, 1641; Rice Vaughan, *Discourse of Coin and Coinage*, 1673; Nicholas Barbon, *Discourse concerning Raising the new money upon*, 1680, in which some of Locke's errors were pointed out; and the author of an anonymous book entitled *Considerations on the East India Trade*, 1701. Practical questions lengthened controversy took place, S. Lema, W. Putter, F. Cradocke, M. Lewis, J. Godfrey, R. Murray, H. Chamberlen, and W. Peterson, founder of the Bank of England (1694), producing many pamphlets on the subject; and the management of the poor, which was treated by Locke, Sir Matthew Hale, R. Haines, T. Firmin, and others.

pushing towards an entire change of the existing system, they yet would gladly have avoided political demolition through the exercise of a royal dictatorship, or contemplated it only as the necessary condition of a new and better order of things. But, though marked off by such tendencies from the purely revolutionary sects, their method and fundamental ideas were negative, resting, as they did, essentially on the basis of the *jus naturæ*. We shall follow in detail these French developments in their special relation to economic science, and afterwards notice the corresponding movements in other European countries which showed themselves before the appearance of Adam Smith, or were at least unaffected by his influence.

### 1. Before Adam Smith.

*France.*—The more liberal, as well as more rational, principles put forward by the English thinkers of the new type began, early in the 18th century, to find an echo in France, where the clearer and more vigorous intellects were prepared for their reception by a sense of the great evils which exaggerated mercantilism, serving as instrument of political ambition, had produced in that country. The impoverished condition of the agricultural population, the oppressive weight and unequal imposition of taxation, and the unsound state of the public finances had produced a general feeling of disquiet, and led several distinguished writers to protest strongly against the policy of Colbert and to demand a complete reform.

Bois-guillebert. The most important amongst them was Pierre Boisguillebert, whose whole life was devoted to these controversies. In his statistical writings (*Détail de la France sous le règne présent*, 1697; *Factum de la France*, 1707) he brings out in gloomy colours the dark side of the age of Louis XIV., and in his theoretic works (*Traité de la nature et du commerce des grains*; *Dissertations sur la nature des richesses de l'argent et des tributs*; and *Essai sur la rareté de l'argent*) he appears as an earnest, even passionate, antagonist of the mercantile school. He insists again and again on the fact that national wealth does not consist in gold and silver, but in useful things, foremost among which are the products of agriculture. He even goes so far as to speak of "argent criminel," which from being the slave of trade, as it ought to be, had become its tyrant. He sets the "genuinely French Snlly" far above the "Italianizing Colbert," and condemns all arbitrary regulations affecting either foreign or internal commerce, especially as regards the corn trade. National wealth does not depend on Governments, whose interference does more harm than good; the natural laws of the economic order of things cannot be violated or neglected with impunity; the interests of the several classes of society in a system of freedom are identical, and those of individuals coincide with that of the state. A similar solidarity exists between different nations; in their economic dealings they are related to the world as individual towns to a nation, and not merely plenty, but peace and harmony, will result from their unfettered intercourse. Then he divides into two classes—those who do nothing and enjoy everything, and those who labour from morning to night often without earning a bare subsistence; the latter he would favour in every way. Here we catch the breath of popular sympathy which fills the social atmosphere of the 18th century. He dwells with special emphasis on the claims of agriculture, which had in France fallen into unmerited neglect, and with a view to its improvement calls for a reform in taxation. He would replace indirect taxes by taxes on income, and would restore the payment of taxes in kind, with the object of securing equality of burden and eliminating every element of the arbitrary. He has some interesting views of a general character: thus he approximates to a correct conception of agricultural rent; and he points to the order in which human wants follow each other,—those of necessity, convenience, comfort, superfluity, and ostentation succeeding in the order named, and ceasing in the inverse order to be felt as wealth decreases. The depreciating tone in which Voltaire speaks of Boisguillebert (*Siccle de Louis XIV.*, chap. 30) is certainly not justified; he had a great economic talent, and his writings contain important germs of truth. But he appears to have exerted little influence, theoretical or practical, in his own time.

Vauban. The same general line of thought was followed by the illustrious Vauban in his economic tracts, especially that bearing the title of *Projet d'une dixme Royale*, 1707. He is deeply impressed with the deplorable condition of the working classes of France in his day. He urges that the aim of the Government should be the welfare of all orders of the community; that all are entitled to like favour

and furtherance; that the often despised and wronged lower class is the basis of the social organization; that labour is the foundation of all wealth, and agriculture the most important species of labour; that the most essential condition of successful industry is freedom; and that all unnecessary or excessive restrictions on manufactures and commerce should be swept away. He protests in particular against the inequalities of taxation, and the exemptions and privileges enjoyed by the higher ranks. With the exception of some duties on consumption he would abolish all the existing taxes, and substitute for them a single tax on income and land, impartially applied to all classes, which he describes under the name of "Dixme Royale," that is to say, a tenth in kind of all agricultural produce, and a tenth of money income chargeable on manufacturers and traders.

The liberal and humane spirit of Fénelon led him to aspire after Fénelon. freedom of commerce with foreign nations, and to preach the doctrine that the true superiority of one state over another lies in the number indeed, but also in the morality, intelligence, and industrious habits of its population. The *Télémaque*, in which these views were presented in an attractive form, was welcomed and read amongst all ranks and classes, and was thus an effective organ for the propagation of opinion.

After these writers there is a marked blank in the field of French economic thought, broken only by the *Réflexions Politiques sur les Finances et le Commerce* (1738) of Dutot, a pupil of Law, and the semi-mercantilist *Essais Politiques sur le Commerce* (1731) of Mélon, till we come to the great name of Montesquieu. The *Esprit des Montes-Louis*, so far as it deals with economic subjects, is written upon quiet, the whole from a point of view adverse to the mercantile system, especially in his treatment of money, though in his observations on colonies and elsewhere he falls in with the ideas of that system. His immortal service, however, was not rendered by any special research, but by his enforcement of the doctrine of natural laws regulating social no less than physical phenomena. There is no other thinker of importance on economic subjects in France till the appearance of the physiocrats, which marks an epoch in the history of the science.

The heads of the physiocratic school were François Quesnay (1694–1774) and Jean Claude Marie Vincent, crats. sieur de Gournay (1712–1759). The principles of the school had been put forward in 1755 by Cantillon, a French merchant of Irish extraction (*Essai sur la nature du Commerce en général*), whose biography Jevons has elucidated, and whom he regards as the true founder of political economy; but it was in the hands of Quesnay and Gournay that they acquired a systematic form, and became the creed of a united group of thinkers and practical men, bent on carrying them into action. The members of the group called themselves "les économistes," but it is more convenient, because unambiguous, to designate them by the name "physiocrates," invented by Dupont de Nemours, who was one of their number. In this name, intended to express the fundamental idea of the school, much more is implied than the subjection of the phenomena of the social, and in particular the economic, world to fixed relations of co-existence and succession. This is the positive doctrine which lies at the bottom of all true science. But the law of nature referred to in the title of the sect was something quite different. The theological dogma which represented all the movements of the universe as directed by divine wisdom and benevolence to the production of the greatest possible sum of happiness had been transformed in the hands of the metaphysicians into the conception of a *jus naturæ*, a harmonious and beneficial code established by the favourite entity of these thinkers, Nature, antecedent to human institutions, and furnishing the model to which they should be made to conform. This idea, which Buckle apparently supposes to have been an invention of Hutcheson's, had come down through Roman juridical theory from the speculations of Greece. It was taken in hand by the modern negative school from Hobbes to Rousseau, and used as a powerful weapon of assault upon the existing order of society, with which the "natural" order was perpetually contrasted as offering the perfect type from which fact had deplorably diverged. The theory received different applications according to the diversity of minds or circumstances. By some it was

directed against the artificial manners of the times, by others against contemporary political institutions; it was specially employed by the physiocrats in criticizing the economic practice of European Governments.

The general political doctrine is as follows. Society is composed of a number of individuals all having the same natural rights. If all do not possess (as some members of the negative school maintained) equal capacities, each can at least best understand his own interest, and is led by nature to follow it. The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each, just so far as it is inconsistent with the rights of the others. Government, though necessary, is a necessary evil; and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere, this implies the right of the individual to such natural enjoyments as he can acquire by his labour. That labour, therefore, should be undisturbed and unfettered; and its fruits should be guaranteed to the possessor; in other words, property should be sacred. Each citizen must be allowed to make the most of his labour; and therefore freedom of exchange should be ensured, and competition in the market should be unrestricted, no monopolies or privileges being permitted to exist.

The physiocrats then proceed with the economic analysis as follows. Only those labours are truly "productive" which add to the quantity of raw materials available for the purposes of man; and the real annual addition to the wealth of the community consists of the excess of the mass of agricultural products (including, of course, metals) over their cost of production. On the amount of this "produit net" depends the wellbeing of the community, and the possibility of its advance in civilization. The manufacturer merely gives a new form to the materials extracted from the earth; the higher value of the object, after it has passed through his hands, only represents the quantity of provisions and other materials used and consumed in its elaboration. Commerce does nothing more than transfer the wealth already existing from one hand to another; what the trading classes gain thereby is acquired at the cost of the nation, and it is desirable that its amount should be as small as possible. The occupations of the manufacturer and merchant, as well as the liberal professions, and every kind of personal service, are "useful" indeed, but they are "sterile," drawing their income, not from any fund which they themselves create, but from the superfluous earnings of the agriculturist. Perfect freedom of trade not only rests, as we have already seen, on the foundation of natural right, but is also recommended by the consideration that it makes the "produit net," on which all wealth and general progress depend, as large as possible. "*Laissez faire, laissez passer*" should therefore be the motto of Governments. The revenue of the state, which must be derived altogether from this net product, ought to be raised in the most direct and simplest way,—namely, by a single impost of the nature of a land tax.

The special doctrine relating to the exclusive productivity of agriculture arose out of a confusion between "value" on the one hand and "matter and energy" on the other. Smith and others have shown that the attempt to fix the character of "sterility" on manufactures and commerce was founded in error. And the proposal of a single *impôt territorial* falls to the ground with the doctrine on which it was based. But such influence as the school exerted depended little, if at all, on these peculiar tenets, which indeed some of its members did not hold. The effective result of its teaching was mainly destructive. It

continued in a more systematic form the efforts in favour of the freedom of industry already begun in England and France. The essential historical office of the physiocrats was to discredit radically the methods followed by the European Governments in their dealings with industry. For such criticism as theirs there was, indeed, ample room: the policy of Colbert, which could be only temporarily useful, had been abusively extended and intensified; Governmental action had intruded itself into the minutest details of business, and every process of manufacture and transaction of trade was hampered by legislative restrictions. It was to be expected that the reformers should, in the spirit of the negative philosophy, exaggerate the vices of established systems; and there can be no doubt that they condemned too absolutely the economic action of the state, both in principle and in its historic manifestations, and pushed the "*laissez faire*" doctrine beyond its just limits. But this was a necessary incident of their connexion with the revolutionary movement, of which they really formed one wing. In the course of that movement, the primitive social contract, the sovereignty of the people, and other dogmas now seen to be untenable were habitually invoked in the region of politics proper, and had a transitory utility as ready and effective instruments of warfare. And so also in the economic sphere the doctrines of natural rights of buying and selling, of the sufficiency of enlightened selfishness as a guide in mutual dealings, of the certainty that each member of the society will understand and follow his true interests, and of the coincidence of those interests with the public welfare, though they will not bear a dispassionate examination, were temporarily useful as convenient and serviceable weapons for the overthrow of the established order. The tendency of the school was undoubtedly to consecrate the spirit of individualism, and the state of non-government. But this tendency, which may with justice be severely condemned in economists of the present time, was then excusable because inevitable. And, whilst it now impedes the work of reconstruction which is for us the order of the day, it then aided the process of social demolition, which was the necessary, though deplorable, condition of a new organization.

These conclusions as to the revolutionary tendencies of the school are not at all affected by the fact that the form of government preferred by Quesnay and some of his chief followers was what they called a legal despotism, which should embrace within itself both the legislative and the executive function. The reason for this preference was that an enlightened central power could more promptly and efficaciously introduce the policy they advocated than an assembly representing divergent opinions, and fettered by constitutional checks and limitations. Turgot, as we know, used the absolute power of the crown to carry into effect some of his measures for the liberation of industry, though he ultimately failed because unsustained by the requisite force of character in Louis XVI. But what the physiocratic idea with respect to the normal method of government was appears from Quesnay's advice to the dauphin, that when he became king he should "do nothing, but let the laws rule," the laws having been of course first brought into conformity with the *jus naturæ*. The partiality of the school for agriculture was in harmony with the sentiment in favour of "nature" and primitive simplicity which then showed itself in so many forms in France, especially in combination with the revolutionary spirit, and of which Rousseau was the most eloquent exponent. It was also associated in these writers with a just indignation at the wretched state in which the rural labourers of France had been left by the scandalous neglect of the superior orders of society—a state of which the

terrible picture drawn by La Bruyère is an indestructible record. The members of the physiocratic group were undoubtedly men of thorough uprightness, and inspired with a sincere desire for the public good, especially for the material and moral elevation of the working classes. Quesnay was physician to Louis XV., and resided in the palace at Versailles; but in the midst of that corrupt court he maintained his integrity, and spoke with manly frankness what he believed to be the truth. And never did any statesman devote himself with greater singleness of purpose or more earnest endeavour to the service of his country than Turgot, who was the principal practical representative of the school.

**Quesnay.** The publications in which Quesnay expounded his system were the following:—two articles, on "Fermiers" and on "Grains," in the *Encyclopédie* of Diderot and D'Alembert (1756, 1757); a discourse on the law of nature in the *Physiocratie* of Dupont de Nemours (1768); *Maximes générales de gouvernement économique d'un royaume agricole* (1758), and the simultaneously published *Tableau Économique avec son explication, ou Extrait des Économies Royales de Sully* (with the celebrated motto "pauvres paysans, pauvre royaume; pauvre royaume, pauvre roi"); *Dialogue sur le commerce et les travaux des artisans*; and other minor pieces. The *Tableau Économique*, though on account of its dryness and abstract form it met with little general favour, may be considered the principal manifesto of the school. It was regarded by the followers of Quesnay as entitled to a place amongst the foremost products of human wisdom, and is named by the elder Mirabeau, in a passage quoted by Adam Smith, as one of the three great inventions which have contributed most to the stability of political societies, the other two being those of writing and of money. Its object was to exhibit by means of certain formulas the way in which the products of agriculture, which is the only source of wealth, would in a state of perfect liberty be distributed among the several classes of the community (namely, the productive classes of the proprietors and cultivators of land, and the unproductive class composed of manufacturers and merchants), and to represent by other formulas the modes of distribution which take place under systems of Governmental restraint and regulation, with the evil results arising to the whole society from different degrees of such violations of the natural order. It follows from Quesnay's theoretic views that the one thing deserving the solicitude of the practical economist and the statesman is the increase of the net product; and he infers also what Smith afterwards affirmed on not quite the same ground, that the interest of the landowner is "strictly and indissolubly connected with the general interest of the society."

**Gournay.** Jean V. Gournay, as we have seen, was regarded as one of the founders of the school, and appears to have exercised some influence even upon the formation of Quesnay's own opinions. With the exception of a translation of Sir Josiah Child, Gournay wrote nothing but memoirs addressed to ministers, which have not seen the light; but we have a full statement of his views in the *Éloge* dedicated to his memory by his illustrious friend Turgot. Whilst Quesnay had spent his youth amidst rural scenes, and had been early familiar with the labours of the field, Gournay had been bred as a merchant, and had passed from the counting-house to the office of intendant of commerce. They thus approached the study of political economy from different sides, and this diversity of their antecedents may in part explain the amount of divergence which existed between their views. Gournay softened the rigour of Quesnay's system, and brought it nearer to the truth, by rejecting what Smith calls its "capital error"—the doctrine, namely, of the unproductiveness of manufactures and commerce. He directed his efforts to the assertion and vindication of the principle of industrial liberty, and it was by him that this principle was formulated in the phrase, since so often heard for good and for evil,

**V. Mirabeau.** "Laissez faire, laissez passer." One of the earliest and most complete adherents of the physiocratic school, as well as an ardent and unwearying propagator of its doctrines, was Victor Mirabeau, whose sincere and independent, though somewhat perverse and whimsical, character is familiar to English readers through Carlyle's essay on his more celebrated son. He had expressed some physiocratic views earlier than Quesnay, but owned the latter for his spiritual father, and adopted most of his opinions, the principal difference being that he was favourable to the *prête* as opposed to the *grande culture*, which latter was preferred by his chief as giving, not indeed the largest gross, but the largest net product. Mirabeau's principal writings were *Ami des Hommes, ou traité sur la population* (1756, 1760), *Théorie de l'impôt* (1760), *Les Économiques* (1769), and *Philosophie rurale, ou Économie générale et politique de l'Agriculture* (1763). The last of these was the earliest complete exposition of the physiocratic system. Another earnest and persevering apostle of the system was Dupont de Nemours (1739–1817), known by his

treatises *De l'exportation et de l'importation des grains* (1764), *De l'origine et des progrès d'une science nouvelle* (1767), *Du commerce de la Compagnie des Indes* (1767), and especially by his more comprehensive work *Physiocratie, ou Constitution naturelle du gouvernement le plus avantageux au genre humain* (1768). The title of this work gave, as has been already mentioned, a name to the school. Another formal exposition of the system, to which Adam Smith Larivière refers as "the most distinct and best connected account" of it, was produced by Mercier-Larivière, under the title *L'Ordre naturel et essentiel des sociétés politiques* (1767), a title which is interesting as embodying the idea of the *jus naturæ*. Both he and Dupont de Nemours professed to study human communities, not only in relation to their economic, but also to their political and general social aspects; but, notwithstanding these larger pretensions, their views were commonly restricted in the main to the economic sphere; at least material considerations decidedly preponderated in their inquiries, as was naively indicated by Larivière when he said, "Property, security, liberty—these comprise the whole social order; the right of property is a tree of which all the institutions of society are branches."

The most eminent member of the group was without doubt Anne Turgot. Robert Jacques Turgot (1727–1781). This is not the place to speak of his noble practical activity, first as intendant of Limoges, and afterwards for a brief period as finance minister, or of the circumstances which led to his removal from office, and the consequent failure of his efforts for the salvation of France. His economic views are explained in the introductions to his edicts and ordinances, in letters and occasional papers, but especially in his *Réflexions sur la formation et la distribution des richesses* (1766). This is a condensed but eminently clear and attractive exposition of the fundamental principles of political economy, as they were conceived by the physiocrats. It embodies, indeed, the elements no less than the sound doctrines of that school; but several subjects, especially the various forms of land-economy, the different employments of capital, and the legitimacy of interest, are handled in a generally just as well as striking manner; and the mode of presentation of the ideas, and the luminous arrangement of the whole, are Turgot's own. The treatise, which contains a surprising amount of matter in proportion to its length, must always retain a place among the classics of the science.

The physiocratic school never obtained much direct popular influence, even in its native country, though it strongly attracted many of the more gifted and earnest minds. Its members, writing on dry subjects in an austere and often heavy style, did not find acceptance with a public which demanded before all things charm of manner in those who addressed it. When Morellet, one of their number, entered the lists with Galiani, it was seen how *esprit* and eloquence could triumph over science, solid indeed, but clumsy in its movements. The physiocratic tenets, which were in fact partially erroneous, were regarded by many as chimerical, and were ridiculed in the contemporary literature, as, for example, the *impôt unique* by Voltaire in his *L'homme aux quarante écus*, which was directed in particular against Mercier-Larivière. It was justly objected to the group that they were too absolute in their view of things; they supposed, as Smith remarks in speaking of Quesnay, that the body politic could thrive only under one precise régime,—that, namely, which they recommended,—and thought their doctrines universally and immediately applicable in practice. They did not, as theorists, sufficiently take into account national diversities, or different stages in social development; nor did they, as politicians, adequately estimate the impediments which ignorance, prejudice, and interested opposition present to enlightened statesmanship. It is possible that Turgot himself, as Grimm suggests, owed his failure in part to the too unbending rigour of his policy and the absence of any attempt at conciliation. Be this as it may, his defeat helped to impair the credit of his principles, which were represented as having been tried and found wanting.

The physiocratic system, after guiding in some degree the policy of the Constituent Assembly, and awakening a few echoes here and there in foreign countries, soon ceased to exist as a living power; but the good elements it comprised were not lost to mankind, being incorporated into

the sounder and more complete construction of Adam Smith.

*Italy.*—In Italy, as in the other European nations, there was little activity in the economic field during the first half of the 18th century. It was then, however, that a really remarkable man appeared, the archdeacon Salustio Antonio Bandini (1677-1760), author of the *Discorso sulla Maremma Senese*, written in 1737, but not published till 1775. The object of the work was to raise the Maremma from the wretched condition into which it had fallen through the decay of agriculture. This decay he showed to be, at least in part, the result of the wretched fiscal system which was in force; and his book led to important reforms in Tuscany, where his name is held in high honour. Not only by Pecchio and other Italian writers, but by Roscher also, he is alleged to have anticipated some leading doctrines of the physiocrats, but this claim is disputed. There was a remarkable renaissance of economic studies in Italy during the latter half of the century, partly due to French influence, and partly, it would appear, to improved government in the northern states.

The movement at first followed the lines of the mercantile school. Thus, in Antonio Broggia's *Trattati dei tributi e delle monete e del governo politico della società* (1743), and Girolamo Belloni's *Dissertazione sopra il commercio* (1750), which seems to have had a success and reputation much above its merits, mercantilist tendencies decidedly preponderate. But the most distinguished writer who represented that economic doctrine in Italy in the last century was Antonio Genovesi, a Neapolitan (1712-1769). He felt deeply the depressed intellectual and moral state of his fellow-countrymen, and aspired after a revival of philosophy and reform of education as the first condition of progress and wellbeing. With the object of protecting him from the theological persecutions which threatened him on account of his advanced opinions, Bartolomeo Intieri, of whom we shall hear again in relation to Galiani, founded in 1755, expressly for Genovesi, a chair of commerce and mechanics, one of the conditions of foundation being that it should never be filled by a monk. This was the first professorship of economics established in Europe; the second was founded at Stockholm in 1758, and the third in Lombardy ten years later, for Beccaria. The fruit of the labours of Genovesi in this chair was his *Lezioni di commercio, ossia di economia civile* (1769), which contained the first systematic treatment of the whole subject which had appeared in Italy. As the model for Italian imitation he held up England, a country for which, says Pecchio, he had a predilection almost amounting to fanaticism. He does not rise above the false economic system which England then pursued; but he rejects some of the grosser errors of the school to which he belonged; he advocates the freedom of the corn trade, and deprecates regulation of the interest on loans. In the spirit of his age, he denounces the relics of mediæval institutions, such as entails and tenures in mortmain, as impediments to the national prosperity. Ferdinando Galiani was another distinguished disciple of the mercantile school. Before he had completed his twenty-first year he published a work on money (*Della moneta libri cinque*, 1750), the principles of which are supposed to have been dictated by two experienced practical men, the marquis Ruffaceini and Bartolomeo Intieri, whose name we have already

ence of the modern spirit, and in closest harmony with the general movement which was impelling the Western nations towards a new social order, Cesare Beccaria (1738-1794) holds a foremost place. He is best known by his celebrated treatise *Dei delitti e delle pene*, by which Voltaire said he had made himself a benefactor of all Europe, and which, we are told, has been translated into twenty-two languages. The empress Catherine having invited him to fix his residence at St Petersburg, the Austrian Government of Lombardy, in order to keep him at home, established expressly for him a chair of political economy; and in his *Elementi di economia pubblica* (1769-1771; not published, however, till 1804) are embodied his teachings as professor. The work is unfinished: he had divided the whole subject under the heads of agriculture, manufactures, commerce, taxation, government; but he has treated adequately only the first two heads, and the last two not at all, having been called to take part in the councils of the state. He was in some degree under the influence of physiocratic ideas, and holds that agriculture is the only strictly productive form of industry, whilst manufacturers and artisans are a sterile class. He was strongly opposed to monopolies and privileges, and to corporations in arts and trades; in general he warmly advocated internal industrial freedom, though in regard to foreign commerce a protectionist. In the special case of the corn trade he was not, any more than Galiani, a partisan of absolute liberty. His exposition of economic principles is concise and sententious, and he often states correctly the most important considerations relating to his subject without adding the developments which would be desirable to assist comprehension and strengthen conviction. Thus on "production capital" (*capitali fondatori*), as distinct from "revenue capital," in its application to agriculture, he presents in a condensed form essentially the same explanations as Turgot about the same time gave; and on the division of labour and the circumstances which cause different rates of wages in different employments, he in substance comes near to Smith, but without the fulness of illustration which is so attractive a feature of the *Wealth of Nations*. Pietro Verri (1728-1797), Verri, an intimate and life-long friend of Beccaria, was for twenty-five years one of the principal directors of the administration of Lombardy, in which capacity he originated many economic and other reforms. In his *Riflessioni sulle leggi vincolanti, principalmente nel commercio de' grani* (written in 1769, printed in 1796), he considers the question of the regulation of the corn trade both historically and in the light of theoretic principles, and arrives at the conclusion that liberty is the best remedy against famine and against excessive fluctuations of price. He is generally opposed to Governmental interference with internal commerce, as well as to trade corporations, and the attempts to limit prices or fix the rate of interest, but is in favour of the protection of national industry by a judiciously framed tariff. These views are explained in his *Meditazioni sull'economia politica* (1771), an elementary treatise on the science, which was received with favour, and translated into several foreign languages. A primary principle with him is what he calls the augmentation of reproduction—that is, in Smith's language, of "the annual produce of the land and labour" of a nation; and by its tendency to promote or to restrict this augmentation he tests every enactment and institution. Accordingly, unlike Beccaria, he prefers the *petite* to the *grande culture*, as giving a larger total produce. In dealing with taxation, he rejects the physiocratic proposal of a single *impôt territorial*. Giovanni R. Carli (1720-1795), Carli, also an official promoter of the reforms in the government of Austrian Lombardy, besides learned and sound treatises on money, was author of *Ragionamenti sopra i bilanci economici delle nazioni*, in which he shows the falsity of the notion that a state gains or loses in foreign commerce according to the so-called balance of trade. In his letter to Pompeo Neri *Sul libero commercio de' grani* (1771), he takes up a position similar to that of Galiani, regarding the question of the freedom of the corn trade as not so much a scientific as an administrative one, to be dealt with differently under different local or other conditions. Rejecting the physiocratic doctrine of the exclusive productiveness of agriculture, he illustrates in an interesting way the necessity of various economic classes in a society, and the reflex agency of manufactures in stimulating the cultivation of the soil. Giambattista Vasco (1733-1796) wrote discourses on several questions proposed by academies and sovereigns. In these he condemns trade corporations and the attempts by Governments to fix the price of bread and to limit the interest on loans. In advocating the system of a peasant proprietary, he suggests that the law should determine the minimum and maximum portions of land which a citizen should be permitted to possess. He also, with a view to prevent the undue accumulation of property, proposes the abolition of the right of bequest, and the equal division of the inheritance amongst the children of the deceased. Gaetano Filangieri (1752-1788), one of the Italian writers of the last century, whose names are most widely known throughout Europe, devoted to economic questions the second book of his *Scienza della legislazione* (5 vols., 1780-1785). Filled with reforming ardour and a passionate patriotism, he employed his vehement eloquence in denouncing all the abuses of his time. Apparently without any

knowledge of Adam Smith, he insists on unlimited freedom of trade, calls for the abolition of the mediæval institutions which impeded production and national wellbeing, and condemns the colonial system then followed by England, Spain, and Holland. He prophesies, as Raynal and Genovesi had done before him, that all America would one day be independent, a prediction which probably helped to elicit Benjamin Franklin's tribute of admiration for his work. Rather a propagator than a discoverer, he sometimes adopted from others erroneous opinions, as, for example, when he approves the *impôt unique* of the physiocrats. On the whole, however, he represents the most advanced political and social tendencies of his age; whilst strongly contrasted with Beccaria in temperament and style, he was a worthy labourer in the same cause of national and universal progress.

Ricci.

Ludovico Ricci (1742-1799) was author of an able report *Sulla riforma degli istituti pii della città di Modena* (1787). He treated the subject of poor relief and charitable institutions in so general a way that the work possesses a universal and permanent interest. He dwells on the evils of indiscriminate relief as tending to increase the misery it seeks to remove, and as lowering the moral character of a population. He exposes especially the abuses connected with lying-in and foundling hospitals. There is much in him which is akin to the views of Malthus; like him he is opposed to any state provision for the destitute, who ought, he thinks, to be left to voluntary private beneficence. Ferdinando Paoletti (1717-1801) was an excellent and public-spirited priest, who did much for the diffusion of the agricultural population of Tuscany, and the taxes which pressed upon them. He corresponded with the "Friend of Men", and appears to have accepted the physiocratic doctrine, at least in their general substance. He was author of *Pensieri sopra l'agricoltura* (1769), and of *I veri mezzi di render felice la società* (1772); in the latter he advocates the freedom of the corn trade. The tract *Il Colbertismo* (1791) by Count Francesco Mengotti is a vigorous protest against the extreme policy of prohibition and protection, which may still be read with interest. Mengotti also wrote (1791) a treatise *Del commercio de' Romani*, directed mainly against the exaggerations of Huot in his *Histoire du commerce et de la navigation des anciens* (1716), and useful as marking the broad difference between the ancient and modern civilizations.

Paoletti.

Mengotti.

Ortes.

Here lastly may be mentioned another Italian thinker who, eminently original and even eccentric, cannot easily be classed among his contemporaries, though some Continental writers of our own century have exhibited similar modes of thought. This was Giannaria Ortes (1713-1790). He is opposed to the liberalist tendencies of his time, but does not espouse the doctrines of the mercantile system, rejecting the theory of the balance of trade and demanding commercial freedom. It is in the Middle Ages that he finds his social and economic type. He advocates the maintenance of church property, is averse to the ascendancy of the money power, and has the mediæval dislike for interest on loans. He entertains the singular idea that the wealth of communities is always and everywhere in a fixed ratio to their population, the latter being determined by the former. Poverty, therefore, necessarily waits on wealth, and the rich, in becoming so, only gain what the poor lose. Those who are interested in the improvement of the condition of the people labour in vain, so long as they direct their efforts to the increase of the sum of the national wealth, which it is beyond their power to alter, instead of to the distribution of that wealth, which it is possible to modify. The true remedy for poverty lies in mitigating the gain-pursuing propensities in the rich and in men of business. Ortes studied in a separate work the subject of population; he formulates its increase as "geometrical," but recognizes that, as a limit is set to such increase amongst the lower animals by mutual destruction, so is it in the human species by "reason"—the "prudential restraint" of which Malthus afterwards made so much. He regards the institution of celibacy as no less necessary and advantageous than that of marriage. He enunciates what has since been known as the "law of diminishing returns to agricultural industry." He was careless as to the diffusion of his writings; and hence they remained almost unknown till they were included in the Custodi collection of Italian economists, when they attracted much attention by the combined sagacity and waywardness which marked their author's intellectual character.

*Spain.*—The same breath of a new era which was in the air elsewhere in Europe made itself felt also in Spain.

Ustariz.

In the earlier part of the 18th century Gerónimo Ustariz had written his *Teoría y Práctica del Comercio y Marina* (1724; published, 1740; Eng. transl. by John Kippax, 1751; French by Forbonnais, 1753), in which he carries mercantile principles to their utmost extreme.

Campo-  
manes.

The reforming spirit of the latter half of the century was best represented in that country by Pedro Rodríguez, count of Campomanes (1723-1802). He pursued with ardour the same studies and in some degree the same policy as his illustrious contemporary

Turgot, without, however, having arrived at so advanced a point of view. He was author of *Respuesta fiscal sobre abolir la tasa y establecer el comercio de granos* (1764), *Discurso sobre el fomento de la industria popular* (1774), and *Discurso sobre la educación de los artesanos y su fomento* (1775). By means of these writings, justly eulogized by Robertson, as well as by his personal efforts as minister, he sought to establish the freedom of the corn trade, to remove the hindrances to industry arising from mediæval survivals, to give a large development to manufactures, and to liberate agriculture from the odious burdens to which it was subject. He saw that, notwithstanding the enlightened administration of Charles III., Spain still suffered from the evil results of the blind confidence reposed by her people in her gold mines, and enforced the lesson that the real sources of the wealth and power of his country must be sought, not in America, but in her own industry.

In both Italy and Spain, as is well observed by Comte, the impulse towards social change took principally the direction of economic reform, because the pressure exercised by Governments prevented so large a measure of free speculation in the fields of philosophy and general politics as was possible in France. In Italy, it may be added, the traditions of the great industrial past of the northern cities of that country also tended to fix attention chiefly on the economic side of public policy and legislation.

*Germany.*—We have seen that in Italy and England political economy had its beginnings in the study of practical questions relating chiefly to money or to foreign commerce. In Germany it arose (as Roscher has shown) out of the so-called cameralistic sciences. From the end of the Middle Ages there existed in most German countries a council, known as the Kammer (Lat. *camera*), which was occupied with the management of the public domain and the guardianship of regal rights. The emperor Maximilian found this institution existing in Burgundy, and established, in imitation of it, aulic councils at Innsbruck and Vienna in 1498 and 1501. Not only finance and taxation, but questions also of economic police, came to be intrusted to these bodies. A special preparation became necessary for their members, and chairs of cameralistic science were founded in universities for the teaching of the appropriate body of doctrine. One side of the instruction thus given borrowed its materials from the sciences of external nature, dealing, as it did, with forestry, mining, general technology, and the like; the other related to the conditions of national prosperity as depending on human relations and institutions; and out of the latter German political economy was at first developed.

In no country had mercantilist views a stronger hold than in Germany, though in none, in the period we are now considering, did the system of the balance of trade receive a less extensive practical application. All the leading German economists of the 17th century—Bornitz, Besold, Klock, Becher, Horneck, Seekendorf, and Schröder—stand on the common basis of the mercantile doctrine. And the same may be said of the writers of the first half of the 18th century in general, and notably of Justi (d. 1771), who was the Justi, author of the first systematic German treatise on political economy, a work which, from its currency as a text book, had much effect on the formation of opinion. Only in Zincke (1692-1769) do we find Zincke, occasional expressions of a circle of ideas at variance with the dominant system, and pointing in the direction of industrial freedom. But these writers, except from the national point of view, are unimportant, not having exercised any influence on the general movement of European thought.

The principles of the physiocratic system met with a certain Karl amount of favour in Germany. Karl Friedrich, margrave of Baden, Friedrich wrote for the use of his sons an *Abriß des principes d'Économie Politique*, 1772, which is in harmony with the doctrines of that system. It possesses, however, little scientific value. Schlettwein (1731-1802) and Mauvillon (1743-1794) were followers of the same school. Theodor Schmalz (1764-1831), who is commonly named Schmalz, as "the last of the physiocrats," may be here mentioned, though somewhat out of the historic order. He compares Colbertism with the Ptolemaic system, physiocracy with the Copernican,—"a" Smith he represents as the Tycho Brahe of political economy,—"a" man of eminent powers, who could not resist the force of truth in the physiocrats, but partly could not divest himself of rooted prejudices, and partly was ambitious of the fame of a discoverer and a reconciler of divergent systems. Though Smith was now "the

fashion," Schmalz could not doubt that Quesnay's doctrine was alone true, and would ere long be triumphant everywhere.

Sonnenfels. Just before the appearance of Smith, as in England Stuart, and in Italy Genovesi, so in Austria Sonnenfels (1733-1817), the first distinguished economist of that country, sought to present the mercantile system in a modified and more enlightened form; and his work (*Grundsätze der Polizei, Handlung, und Finanz*, 1765; 8th ed., 1822) exercised even during a considerable part of the present century much influence on opinion and on policy in Austria.

Möser. But the greatest German economist of the 18th century was, in Roscher's opinion, Justus Möser (1720-1794), the author of *Patriotische Phantasien* (1774), a series of fragments, which, Goethe nevertheless declares, form "ein wahrhaftes Ganzes." The poet was much influenced by Möser in his youth, and has eulogized in the *Dichtung und Wahrheit* his spirit, intellect, and character, and his thorough insight into all that goes on in the social world. Whilst others occupied themselves with larger and more prominent public affairs and transactions, Möser observed and reproduced the common daily life of his nation, and the thousand "little things" which compose the texture of popular existence. He has been compared to Franklin for the homeliness, verve, and freshness of his writings. In opinions he is akin to the Italian Ortes. He is opposed to the whole spirit of the "Aufklärung," and to the liberal and rationalistic direction of which Smith's work became afterwards the expression. He is not merely conservative but reactionary, manifesting a preference for mediæval institutions such as the trade guilds, and, like Carlyle in our own time, seeing advantages even in serfdom, when compared with the sort of freedom enjoyed by the modern drudge. He has a marked antipathy for the growth of the money power and of manufactures on the large scale, and for the highly developed division of labour. He is opposed to absolute private property in land, and would gladly see revived such a system of restrictions as in the interest of the state, the commune, and the family were imposed on mediæval ownership. In his wayward and caustic style, he often criticizes effectively the doctrinaire narrowness of his contemporaries, throws out many striking ideas, and in particular sheds real light on the economic phenomena and general social conditions of the Middle Ages.

## 2. Adam Smith, with his Immediate Predecessors and his Followers.

England.—The stagnation in economic inquiry which showed itself in England in the early part of the 18th century was not broken by any notable manifestation before 1735, when Bishop Berkeley put forward in his *Querist*, with much force and point, views opposed to those of the mercantile school on the nature of national wealth and the functions of money, though not without an admixture of grave error. But soon a more decisive advance was made. Whilst in France the physiocrats were working after their own fashion towards the construction of a definitive system of political economy, a Scottish thinker of the first order was elucidating, in a series of short but pregnant essays, some of the fundamental conceptions of the science. What had been written on these questions in the English language before his time had remained almost altogether within the limits of the directly practical sphere. With Locke, indeed, the general system of the modern critical philosophy had come into relation with economic inquiry, but only in a partial and indeterminate way. But in Hume the most advanced form of this philosophy was represented, and his appearance in the field of economics decisively marks the tendency of the latter order of speculation to place itself in connexion with the largest and deepest thought on human nature and general human history. Most of the essays here referred to first appeared in 1752, in a volume entitled *Political Discourses*, and the number was completed in the collection of *Essays and Treatises on Several Subjects*, published in the following year. The most important of them are those on Commerce, on Money, on Interest, and on the Balance of Trade. Yet these should not be separated from the rest, for, notwithstanding the unconnected form of these little treatises, there runs through them a profound unity of thought, so that they indeed compose in a certain sense an economic system. They exhibit in full measure Hume's wonderful acuteness and subtlety, which

indeed sometimes dispose him to paradox, in combination with the breadth, the absence of prejudice, and the social sympathies which so eminently distinguish him; and they offer, besides, the charm of his easy and natural style and his rare power of lucid exposition.

In the essay on money he refutes the mercantilist error, which tended to confound it with wealth. "Men and commodities," he says, "are the real strength of any community." "In the national stock of labour consists all real power and riches." Money is only the oil which makes the movements of the mechanism of commerce more smooth and easy. He shows that, from the domestic as distinguished from the international point of view, the absolute quantity of money, supposed as of fixed amount, in a country is of no consequence, whilst an excessive quantity, larger, that is, than is required for the interchange of commodities, may be injurious as raising prices and driving foreigners from the home markets. He goes so far, in one or two places, as to assert that the value of money is chiefly fictitious or conventional, a position which cannot be defended; but it must not be pressed against him, as he builds nothing on it. He has some very ingenious observations (since, however, questioned by J. S. Mill) on the effects of the increase of money in a country in stimulating industry during the interval which takes place before the additional amount is sufficiently diffused to alter the whole scale of prices. He shows that the fear of the money of an industrious community being lost to it by passing into foreign countries is groundless, and that, under a system of freedom, the distribution of the precious metals which is adapted to the requirements of trade will spontaneously establish itself. "In short, a Government has great reason to preserve with care its people and its manufactures; its money it may safely trust to the course of human affairs without fear or jealousy."

A very important service was rendered by his treatment of the rate of interest. He exposes the erroneous idea often entertained that it depends on the quantity of money in a country, and shows that the reduction of it must in general be the result of "the increase of industry and frugality, of arts and commerce," so that it may serve as a barometer, its lowness being an almost infallible sign of the flourishing condition of a people. It may be observed in passing that in the essay devoted to this subject he brings out a principle of human nature which economists too often overlook, "the constant and insatiable desire of the mind for exercise and employment," and the consequent action of *ennui* in prompting to exertion.

With respect to commerce, he points to its natural foundation in what has since been called "the territorial division of labour," and proves that the prosperity of one nation, instead of being a hindrance, is a help to that of its neighbours. "Not only as a man, but as a British subject," he says, "I pray for the flourishing commerce of Germany, Spain, Italy, and even France itself." He condemns the "numberless bars, obstructions, and imposts which all nations of Europe, and none more than England, have put upon trade." Yet on the question of protection to national industry he is not quite at the free-trade point of view, for he approves of a tax on German linen as encouraging home manufactures, and of a tax on brandy as increasing the sale of rum and supporting our southern colonies. Indeed it has been justly observed that there are in him several traces of a refined mercantilism, and that he represents a state of opinion in which the transition from the old to the new views is not yet completely effected.

We cannot do more than refer to the essay on taxes, in which, amongst other things, he repudiates the *impôt unique* of the physiocrats, and to that on public credit, in which he criticizes the "new paradox that public incumbrances are of themselves advantageous, independent of the necessity of contracting them," and objects, perhaps too absolutely, to the modern expedient of raising the money required for national enterprises by way of loan, and so shifting our burdens upon the shoulders of posterity.

The characteristics of Hume which are most important in the history of economic investigation are (1) his practice of bringing economic facts into connexion with all the weighty interests of social and political life, and (2) his tendency to introduce the historical spirit into the study of those facts. He admirably illustrates the mutual action of the several branches of industry, and the influences of progress in the arts of production and in commerce on general civilization, exhibits the striking contrasts of the ancient and modern system of life (see especially the essay *On the Populousness of Ancient Nations*), and considers almost every phenomenon which comes under discussion in its relations to the contemporary stage of social development. It cannot be doubted that Hume exercised a most important influence on Adam Smith, who

in the *Wealth of Nations* calls him "by far the most illustrious philosopher and historian of the present age," and who esteemed his character so highly that, after a friendship of many years had been terminated by Hume's decease, he declared him to have "approached as nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will permit."

**Tucker.** Josiah Tucker, dean of Gloucester (d. 1799), holds a distinguished place among the immediate predecessors of Smith. Most of his numerous productions had direct reference to contemporary questions, and, though marked by much sagacity and penetration are deficient in permanent interest. In some of these he urged the impolicy of restrictions on the trade of Ireland, advocated a union of that country with England, and recommended the recognition of the independence of the United States of America. The most important of his general economic views are those relating to international commerce. He is an ardent supporter of free-trade doctrines, which he bases on the principles that there is between nations no necessary antagonism, but rather a harmony, of interests, and that their several natural advantages and different aptitudes naturally prompt them to exchange. He had not, however, got quite clear of mercantilism, and favoured bounties on exported manufactures and the encouragement of population by a tax on celibacy. Dupont, and after him Blanqui, represent Tucker as a follower of the physiocrats, but there seems to be no ground for this opinion except his agreement with them on the subject of the freedom of trade. Turgot translated into French his *Important Questions on Commerce* (1755).

**Steuart.** In 1767 was published Sir James Steuart's *Inquiry into the Principles of Political Economy*. This was one of the most unfortunate of books. It was the most complete and systematic survey of the science from the point of view of moderate mercantilism which had appeared in England. Steuart was a man of no ordinary abilities, and had prepared himself for his task by long and serious study. But the time for the mercantile doctrines was past, and the system of natural liberty was in possession of an intellectual ascendancy which foreshadowed its political triumph. Nine years later the *Wealth of Nations* was given to the world, a work as superior to Steuart's in attractiveness of style as in scientific soundness. Thus the latter was predestined to fail, and in fact never exercised any considerable theoretic or practical influence. Smith never quotes or mentions it; being acquainted with Steuart, whose conversation he said was better than his book, he probably wished to keep clear of controversy with him. The German economists have examined Steuart's treatise more carefully than English writers have commonly done; and they recognize its high merits, especially in relation to the theory of value and the subject of population. They have also pointed out that, in the spirit of the best recent research, he has dwelt on the special characters which distinguish the economies proper to different nations and different grades in social progress.

**Adam Smith.** Coming now to the great name of Adam Smith (1723-1790), it is of the highest importance that we should rightly understand his position and justly estimate his claims. It is plainly contrary to fact to represent him, as some have done, as the creator of political economy. The subject of social wealth had always in some degree, and increasingly in recent times, engaged the attention of philosophic minds. The study had even indisputably assumed a systematic character, and, from being an assemblage of fragmentary disquisitions on particular questions of national interest, had taken the form, notably in Turgot's *Réflexions*, of an organized body of doctrine. The truth is that Smith took up the science when it was already considerably advanced; and it was this very circumstance which enabled him, by the production of a classical treatise, to render most of his predecessors obsolete. But, whilst all the economic labours of the preceding centuries prepared the way for him, they did not anticipate his work. His appearance at an earlier stage, or without those previous labours, would be inconceivable; but he built, on the foundation which had been laid by others, much of his own that was precious and enduring.

Even those who do not fall into the error of making Smith the creator of the science, often separate him too broadly from Quesnay and his followers, and represent the history of modern economics as consisting of the successive rise and reign of three doctrines—the mercantile, the

physiocratic, and the Smithian. The last two are, it is true, at variance in some even important respects. But it is evident, and Smith himself felt, that their agreements were much more fundamental than their differences; and, if we regard them as historical forces, they must be considered as working towards identical ends. They both urged society towards the abolition of the previously prevailing industrial policy of European Governments; and their arguments against that policy rested essentially on the same grounds. Whilst Smith's criticism was more searching and complete, he also analysed more correctly than the physiocrats some classes of economic phenomena,—in particular dispelling the illusions into which they had fallen with respect to the unproductive nature of manufactures and commerce. Their school disappeared from the scientific field, not merely because it met with a political check in the person of Turgot, but because, as we have already said, the *Wealth of Nations* absorbed into itself all that was valuable in their teaching, whilst it continued more effectually the impulse they had given to the necessary work of demolition.

The history of economic opinion in modern times, down to the third decade of our own century, is, in fact, strictly bipartite. The first stage is filled with the mercantile system, which, as we have shown, was rather a practical policy than a speculative doctrine, and which came into existence as the spontaneous growth of social conditions acting on minds not trained to scientific habits. The second stage is occupied with the gradual rise and ultimate ascendancy of another system founded on the idea of the right of the individual to an unimpeded sphere for the exercise of his economic activity. With the latter, which is best designated as the "system of natural liberty," we ought to associate the memory of the physiocrats as well as that of Smith, without, however, maintaining their services to have been equal to his.

The teaching of political economy was in the Scottish universities associated with that of moral philosophy. Smith, as we are told, conceived the entire subject he had to treat in his public lectures as divisible into four heads, the first of which was natural theology, the second ethics, the third jurisprudence; whilst in the fourth "he examined those political regulations which are founded upon expediency, and which are calculated to increase the riches, the power, and the prosperity of a state." The last two branches of inquiry are regarded as forming but a single body of doctrine in the well-known passage of the *Theory of Moral Sentiments* in which the author promises to give in another discourse "an account of the general principles of law and government, and of the different revolutions they have undergone in the different ages and periods of society, not only in what concerns justice, but in what concerns police, revenue, and arms, and whatever else is the subject of law." This shows how little it was Smith's habit to separate (except provisionally), in his conceptions or his researches, the economic phenomena of society from all the rest. The words above quoted have, indeed, been not unjustly described as containing "an anticipation, wonderful for his period, of general sociology, both statical and dynamical, an anticipation which becomes still more remarkable when we learn from his literary executors that he had formed the plan of a connected history of the liberal sciences and elegant arts, which must have added to the branches of social study already enumerated a view of the intellectual progress of society." Though these large designs were never carried out in their integrity, as indeed at that period they could not have been adequately realized, it has resulted from them that, though economic phenomena form the special subject of the *Wealth of Nations*, Smith yet incorporated

into that work much that relates to the other social aspects, incurring thereby the censure of some of his followers, who insist with pedantic narrowness on the strict isolation of the economic domain.

There has been much discussion on the question—What is the scientific method followed by Smith in his great work? By some it is considered to have been purely deductive, a view which Buckle has perhaps carried to the greatest extreme. He asserts that in Scotland the inductive method was unknown, that the inductive philosophy exercised no influence on Scottish thinkers; and, though Smith spent some of the most important years of his youth in England, where the inductive method was supreme, and though he was widely read in general philosophical literature, he yet thinks he adopted the deductive method because it was habitually followed in Scotland,—and this though Buckle maintains that it is the only appropriate, or even possible, method in political economy, which surely would have been a sufficient reason for choosing it. That the inductive spirit exercised no influence on Scottish philosophers is certainly not true; as will be presently shown, Montesquien, whose method is essentially inductive, was in Smith's time studied with quite peculiar care and regarded with special veneration by Smith's fellow-countrymen. As to Smith himself, what may justly be said of him is that the deductive bent was certainly not the predominant character of his mind, nor did his great excellence lie in the "dialectic skill" which Buckle ascribes to him. What strikes us most in his book is his wide and keen observation of social facts, and his perpetual tendency to dwell on these and elicit their significance, instead of drawing conclusions from abstract principles by elaborate chains of reasoning. It is this habit of his mind which gives us, in reading him, so strong and abiding a sense of being in contact with the realities of life.

That Smith does, however, largely employ the deductive method is certain; and that method is quite legitimate when the premises from which the deduction sets out are known universal facts of human nature and properties of external objects. Whether this mode of proceeding will carry us far may indeed well be doubted; but its soundness cannot be disputed. But there is another vicious species of deduction which, as Cliffe Leslie has shown, seriously tainted the philosophy of Smith,—in which the premises are not facts ascertained by observation, but the same *a priori* assumptions, half theological half metaphysical, respecting a supposed harmonious and beneficent natural order of things which we found in the physiocrats, and which, as we saw, were embodied in the name of that sect. In his view, Nature has made provision for social wellbeing by the principle of the human constitution which prompts every man to better his condition: the individual aims only at his private gain, but in doing so is "led by an invisible hand" to promote the public good, which was no part of his intention; human institutions, by interfering with the action of this principle in the name of the public interest, defeat their own end; but, when all systems of preference or restraint are taken away, "the obvious and simple system of natural liberty establishes itself of its own accord." This theory is, of course, not explicitly presented by Smith as a foundation of his economic doctrines, but it is really the secret substratum on which they rest. Yet, whilst such latent postulates warped his view of things, they did not entirely determine his method. His native bent towards the study of things as they are preserved him from extravagances into which many of his followers have fallen. But besides this, as Leslie has pointed out, the influence of Montesquien tended to counterbalance the theoretic prepossessions produced by the doctrine of the *jus naturæ*.

That great thinker, though he could not, at his period understand the historical method which is truly appropriate to sociological inquiry, yet founded his conclusions on induction. It is true, as Comte has remarked, that his accumulation of facts, borrowed from the most different states of civilization, and not subjected to philosophic criticism, necessarily remained on the whole sterile, or at least could not essentially advance the study of society much beyond the point at which he found it. His merit, as we have before mentioned, lay in the recognition of the subjection of all social phenomena to natural laws, not in the discovery of those laws. But this limitation was overlooked by the philosophers of the time of Smith, who were much attracted by the system he followed of tracing social facts to the special circumstances, physical or moral, of the communities in which they were observed. Leslie has shown that Lord Kaimes, Dalrymple, and Millar—contemporaries of Smith, and the last his pupil—were influenced by Montesquien; and he might have added the more eminent name of Ferguson, whose respect and admiration for the great Frenchman are expressed in striking terms in his *History of Civil Society*. We are even informed that Smith himself in his later years was occupied in preparing a commentary on the *Esprit des Lois*. He was thus affected by two different and incongruous systems of thought,—one setting out from an imaginary code of nature intended for the benefit of man, and leading to an optimistic view of the economic constitution founded on enlightened self-interest; the other following inductive processes, and seeking to explain the several states in which human societies are found existing, as results of circumstances or institutions which have been in actual operation. And we find accordingly in his great work a combination of these two modes of treatment—inductive inquiry on the one hand, and, on the other, *a priori* speculation founded on the "Nature" hypothesis. The latter vicious proceeding has in some of his followers been greatly aggravated, while the countervailing spirit of inductive investigation has fallen into the background, and indeed the necessity or utility of any such investigation in the economic field has been sometimes altogether denied.

Some have represented Smith's work as of so loose a texture and so defective in arrangement that it may be justly described as consisting of a series of monographs. But this is certainly an exaggeration. The book, it is true, is not framed on a rigid mould, nor is there any parade of systematic divisions and subdivisions; and this doubtless recommended it to men of the world and of business, for whose instruction it was, at least primarily, intended. But, as a body of exposition, it has the real and pervading unity which results from a mode of thinking homogeneous throughout and the general absence of such contradictions as would arise from an imperfect digestion of the subject.

Smith sets out from the thought that the annual labour of a nation is the source from which it derives its supply of the necessaries and conveniences of life. He does not of course contemplate labour as the only factor in production; but it has been supposed that by emphasizing it at the outset he at once strikes the note of difference between himself on the one hand and both the mercantilists and the physiocrats on the other. The improvement in the productiveness of labour depends largely on its division; and he proceeds accordingly to give his unrivalled exposition of that principle, of the grounds on which it rests, and of its greater applicability to manufactures than to agriculture, in consequence of which the latter relatively lags behind in the course of economic development. The origin of the division of labour he finds in the propensity of human nature "to truck, barter, or exchange one thing for another." He shows that a certain accumulation of capital is a condition precedent of this division, and that the degree to which it can be carried is dependent on the extent of the market. When the division of labour has been established, each member of the society must have recourse to the others for the supply of most of

his wants; a medium of exchange is thus found to be necessary, and money comes into use. The exchange of goods against each other or against money gives rise to the notion of value. This word has two meanings—that of utility, and that of purchasing power; the one may be called value in use, the other value in exchange. Merely mentioning the former, Smith goes on to study the latter. What, he asks, is the measure of value? what regulates the amount of one thing which will be given for another? "Labour," Smith answers, "is the real measure of the exchangeable value of all commodities." "Equal quantities of labour, at all times and places, are of equal value to the labourer." "Labour alone, therefore, never varying in its own value, is alone the ultimate and real standard by which the value of all commodities can at all times and places be estimated and compared. It is their real price; money is their nominal price only." Money, however, is in men's actual transactions the measure of value, as well as the vehicle of exchange; and the precious metals are best suited for this function, as varying little in their own value for periods of moderate length; for distant times, corn is a better standard of comparison. In relation to the earliest social stage, we need consider nothing but the amount of labour employed in the production of an article as determining its exchange value; but in more advanced periods price is complex, and consists in the most general case of three elements—wages, profit, and rent. Wages are the reward of labour. Profit arises as soon as stock, being accumulated in the hands of one person, is employed by him in setting others to work, and supplying them with materials and subsistence, in order to make a gain by what they produce. Rent arises as soon as the land of a country has all become private property; "the landlords, like all other men, love to reap where they never sowed, and demand a rent even for its natural produce." In every improved society, then, these three elements enter more or less into the price of the far greater part of commodities. There is in every society or neighbourhood an ordinary or average rate of wages and profit in every different employment of labour and stock, regulated by principles to be explained hereafter, as also an ordinary or average rate of rent. These may be called the natural rates at the time when and the place where they prevail; and the natural price of a commodity is what is sufficient to pay for the rent of the land, the wages of the labour, and the profit of the stock necessary for bringing the commodity to market. The market price may rise above or fall below the amount so fixed, being determined by the proportion between the quantity brought to market and the demand of those who are willing to pay the natural price. Towards the natural price as a centre the market-price, regulated by competition, constantly gravitates. Some commodities, however, are subject to a monopoly of production, whether from the peculiarities of a locality or from legal privilege: their price is always the highest that can be got; the natural price of other commodities is the lowest which can be taken for any length of time together. The three component parts or factors of price vary with the circumstances of the society. The rate of wages is determined by a "dispute" or struggle of opposite interests between the employer and the workman. A minimum rate is fixed by the condition that they must be at least sufficient to enable a man and his wife to maintain themselves and, in general, bring up a family. The excess above this will depend on the circumstances of the country, and the consequent demand for labour,—wages being high when national wealth is increasing, low when it is declining. The same circumstances determine the variation of profits, but in an opposite direction; the increase of stock, which raises wages, tending to lower profit through the mutual competition of capitalists. "The whole of the advantages and disadvantages of the different employments of labour and stock must, in the same neighbourhood, be either perfectly equal or continually tending to equality;" if one had greatly the advantage over the others, people would crowd into it, and the level would soon be restored. Yet pecuniary wages and profits are very different in different employments,—either from certain circumstances affecting the employments, which recommend or disparage them in men's notions, or from national policy, "which nowhere leaves things at perfect liberty." Here follows Smith's admirable exposition of the causes which produce the inequalities in wages and profits just referred to, a passage affording ample evidence of his habits of nice observation of the less obvious traits in human nature, and also of the operation both of these and of social institutions on economic facts. The rent of land comes next to be considered, as the last of the three elements of price. Rent is a monopoly price, equal, not to what the landlord could afford to take, but to what the farmer can afford to give. "Such parts only of the produce of land can commonly be brought to market, of which the ordinary price is sufficient to replace the stock which must be employed in bringing them thither, together with the ordinary profits. If the ordinary price is more than this, the surplus part will naturally go to the rent of the land. If it is not more, though the commodity may be brought to market, it can afford no rent to the landlord. Whether the price is or is not more depends on the demand." "Rent,

therefore, enters into the price of commodities in a different way from wages and profits. High or low wages and profit are the causes of high or low price; high or low rent is the effect of it."

Rent, wages, and profits, as they are the elements of price, are also the constituents of income; and the three great orders of every civilized society, from whose revenues that of every other order is ultimately derived, are the landlords, the labourers, and the capitalists. The relation of the interests of these three classes to those of society at large is different. The interest of the landlord always coincides with the general interest: whatever promotes or obstructs the one has the same effect on the other. So also does that of the labourer: when the wealth of the nation is progressive, his wages are high; they are low when it is stationary or retrogressive. "The interest of the third order has not the same connexion with the general interest of the society as that of the other two; . . . it is always in some respects different from and opposite to that of the public."

The subject of the second book is "the nature, accumulation, and improvement of stock." A man's whole stock consists of two portions—that which is reserved for his immediate consumption, and that which is employed so as to yield a revenue to its owner. This latter, which is his "capital," is divisible into the two classes of "fixed" and "circulating." The first is such as yields a profit without passing into other hands. The second consists of such goods, raised, manufactured, or purchased, as are sold for a profit and replaced by other goods; this sort of capital is therefore constantly going from and returning to the hands of its owner. The whole capital of a society falls under the same two heads. Its fixed capital consists chiefly of (1) machines, (2) buildings which are the means of procuring a revenue, (3) agricultural improvements, and (4) the acquired and useful abilities of all members of the society (since sometimes known as "personal capital"). Its circulating capital is also composed of four parts—(1) money, (2) provisions in the hands of the dealers, (3) materials, and (4) completed work in the hands of the manufacturer or merchant. Next comes the distinction of the gross national revenue from the net,—the first being the whole produce of the land and labour of a country, the second what remains after deducting the expense of maintaining the fixed capital of the country and that part of its circulating capital which consists of money. Money, "the great wheel of circulation," is altogether different from the goods which are circulated by means of it; it is a costly instrument by means of which all that each individual receives is distributed to him; and the expenditure required, first to provide it, and afterwards to maintain it, is a deduction from the net revenue of the society. In development of this consideration, Smith goes on to explain the gain to the community arising from the substitution of paper money for that composed of the precious metals; and here occurs the remarkable illustration in which the use of gold and silver money is compared to a highway on the ground, that of paper money to a waggon way through the air. In proceeding to consider the accumulation of capital, he is led to the distinction between productive and unproductive labour,—the former being that which is fixed or realized in a particular object or vendible article, the latter that which is not so realized. The former is exemplified in the labour of the manufacturing workman, the latter in that of the menial servant. A broad line of demarcation is thus drawn between the labour which results in commodities or increased value of commodities, and that which does no more than render services: the former is productive, the latter unproductive. "Productive" is by no means equivalent to "useful": the labours of the magistrate, the soldier, the churchman, lawyer, and physician, are, in Smith's sense, unproductive. Productive labourers alone are employed out of capital; unproductive labourers, as well as those who do not labour at all, are all maintained by revenue. In advancing industrial communities, the portion of annual produce set apart as capital, bears an increasing proportion to that which is immediately destined to constitute revenue, either as rent or as profit. Parsimony is the source of the increase of capital; by augmenting the fund devoted to the maintenance of productive hands, it puts in motion an additional quantity of industry, which adds to the value of the annual produce. What is annually saved is as regularly consumed as what is spent, but by a different set of persons, by productive labourers instead of idlers or unproductive labourers; and the former reproduce with a profit the value of their consumption. The prodigal, encroaching on his capital, diminishes, as far as in him lies, the amount of productive labour, and so the wealth of the country; nor is this result affected by his expenditure being on home-made, as distinct from foreign, commodities. Every prodigal, therefore, is a public enemy; every frugal man a public benefactor. The only mode of increasing the annual produce of the land and labour is to increase either the number of productive labourers or the productive powers of those labourers. Either process will in general require additional capital, the former to maintain the new labourers, the latter to provide improved machinery or to enable the employer to introduce a more complete division of labour. In what are commonly called loans of money,

it is not really the money, but the money's worth, that the borrower wants; and the lender really assigns to him the right to a certain portion of the annual produce of the land and labour of the country. As the general capital of a country increases, so also does the particular portion of it from which the possessors wish to derive a revenue without being at the trouble of employing it themselves; and, as the quantity of stock thus available for loans is augmented, the interest diminishes, not merely "from the general causes which make the market price of things commonly diminish as their quantity increases," but because, with the increase of capital, "it becomes gradually more and more difficult to find within the country a profitable method of employing any new capital,"—whence arises a competition between different capitals, and a lowering of profits, which must diminish the price which can be paid for the use of capital, or in other words the rate of interest. It was formerly wrongly supposed, and even Locke and Montesquieu did not escape this error, that the fall in the value of the precious metals consequent on the discovery of the American mines was the real cause of the general lowering of the rate of interest in Europe. But this view, already refuted by Hume, is easily seen to be erroneous. "In some countries the interest of money has been prohibited by law. But, as something can everywhere be made by the use of money, something ought everywhere to be paid for the use of it," and will in fact be paid for it; and the prohibition will only heighten the evil of usury by increasing the risk to the lender. The legal rate should be a very little above the lowest market rate; sober people will then be preferred as borrowers to prodigals and projectors, who at a higher legal rate would have an advantage over them, being alone willing to offer that higher rate.

As to the different employments of capital, the quantity of productive labour put in motion by an equal amount varies extremely according as that amount is employed—(1) in the improvement of lands, mines or fisheries, (2) in manufactures, (3) in wholesale or (4) retail trade. In agriculture "Nature labours along with man," and not only the capital of the farmer is reproduced with his profits, but also the rent of the landlord. It is therefore the employment of a given capital which is most advantageous to society. Next in order come manufactures; then wholesale trade—first the home trade, secondly the foreign trade of consumption, last the carrying trade. All these employments of capital, however, are not only advantageous, but necessary, and will introduce themselves in the due degree, if they are left to the spontaneous action of individual enterprise.

These first two books contain Smith's general economic scheme; and we have stated it as fully as was consistent with the brevity here necessary, because from this formulation of doctrine the English classical school set out, and round it the discussions of more recent times in different countries have in a great measure revolved. Some of the criticisms of his successors and their modifications of his doctrines will come under our notice as we proceed.

The critical philosophers of the 18th century were often destitute of the historical spirit, which was no part of the endowment needed for their principal social office. But some of the most eminent of them, especially in Scotland, showed a marked capacity and predilection for historical studies. Smith was amongst the latter; Knies and others justly remark on the masterly sketches of this kind which occur in the *Wealth of Nations*. The longest and most elaborate of these occupies the third book; it is an account of the course followed by the nations of modern Europe in the successive development of the several forms of industry. It affords a curious example of the effect of doctrinal prepossessions in obscuring the results of historical inquiry. Whilst he correctly describes the European movement of industry, and explains it as arising out of adequate social causes, he yet, in accordance with the absolute principles which tainted his philosophy, protests against it as involving an entire inversion of the "natural order of things." First agriculture, then manufactures, lastly foreign commerce; any other order than this he considers "unnatural and retrograde." Hume, a more purely positive thinker, simply sees the facts, accepts them, and classes them under a general law. "It is a violent method," he says, "and in most cases impracticable, to oblige the labourer to toil in order to raise from the land more than what subsists himself and family. Furnish him with manufactures and commodities, and he

will do it of himself." "If we consult history, we shall find that, in most nations, foreign trade has preceded any refinement in home manufactures, and given birth to domestic luxury."

The fourth book is principally devoted to the elaborate and exhaustive polemic against the mercantile system which finally drove it from the field of science, and has exercised a powerful influence on economic legislation. When protection is now advocated, it is commonly on different grounds from those which were in current use before the time of Smith. He believed that to look for the restoration of freedom of foreign trade in Great Britain would have been "as absurd as to expect that an Oceana or Utopia should be established in it;" yet, mainly in consequence of his labours, that object has been completely attained; and it has lately been said with justice that free trade might have been more generally accepted by other nations if the patient reasoning of Smith had not been replaced by dogmatism. His teaching on the subject is not altogether unqualified; but, on the whole, with respect to exchanges of every kind, where economic motives alone enter, his voice is in favour of freedom. He has regard, however, to political as well as economic interests, and on the ground that "defence is of much more importance than opulence" pronounces the Navigation Act to have been "perhaps the wisest of all the commercial regulations of England." Whilst objecting to the prevention of the export of wool, he proposes a tax on that export as somewhat less injurious to the interest of growers than the prohibition, whilst it would "afford a sufficient advantage" to the domestic over the foreign manufacturer. This is, perhaps, his most marked deviation from the rigour of principle; it was doubtless a concession to popular opinion with a view to an attainable practical improvement. The wisdom of retaliation in order to procure the repeal of high duties or prohibitions imposed by foreign Governments depends, he says, altogether on the likelihood of its success in effecting the object aimed at, but he does not conceal his contempt for the practice of such expedients. The restoration of freedom in any manufacture, when it has grown to considerable dimensions by means of high duties, should, he thinks, from motives of humanity, be brought about only by degrees and with circumspection,—though the amount of evil which would be caused by the immediate abolition of the duties is, in his opinion, commonly exaggerated. The case in which J. S. Mill justified protection—that, namely, in which an industry well-adapted to a country is kept down by the acquired ascendancy of foreign producers—is referred to by Smith; but he is opposed to the admission of this exception for reasons which do not appear to be conclusive. He is perhaps scarcely consistent in approving the concession of temporary monopolies to joint-stock companies undertaking risky enterprises "of which the public is afterwards to reap the benefit."<sup>1</sup>

He is less absolute in his doctrine of Governmental non-interference when he comes to consider in his fifth book the "expenses of the sovereign or the commonwealth." He recognizes as coming within the functions of the state the erection and maintenance of those public institutions and public works which, though advantageous to the society, could not repay, and therefore must not be thrown upon, individuals or small groups of individuals. He remarks in a just historical spirit that the performance of these functions requires very different degrees of expense in the different periods of society. Besides the

<sup>1</sup> Professor Bastable calls our attention to the interesting fact that the proposal of an export duty on wool and the justification of a temporary monopoly to joint-stock companies both appear for the first time in the edition of 1784.

institutions and works intended for public defence and the administration of justice, and those required for facilitating the commerce of the society, he considers those necessary for promoting the instruction of the people. He thinks the public at large may with propriety not only facilitate and encourage, but even impose upon almost the whole body of the people, the acquisition in youth of the most essential elements of education. He suggests as the mode of enforcing this obligation the requirement of submission to a test examination "before any one could obtain the freedom in any corporation, or be allowed to set up a trade in any village or town corporate." Similarly, he is of opinion that some probation, even in the higher and more difficult sciences, might be enforced as a condition of exercising any liberal profession, or becoming a candidate for any honourable office. The expense of the institutions for religious instruction as well as for general education, he holds, may without injustice be defrayed out of the funds of the whole society, though he would apparently prefer that it should be met by the voluntary contributions of those who think they have occasion for such education or instruction. There is much that is sound, as well as interesting and suggestive, in this fifth book, in which he shows a political instinct and a breadth of view by which he is favourably contrasted with the Manchester school. But, if we may say so without disrespect to so great a man, there are traces in it of what is now called Philistinism—a low view of the ends of art and poetry—which arose perhaps in part from personal defect, though it was common enough in even the higher minds in his century. There are also indications of a certain deadness to the lofty aims and perennial importance of religion, which was no doubt chiefly due to the influences of an age when the critical spirit was doing an indispensable work, in the performance of which the transitory was apt to be confounded with the permanent.

For the sake of considering as a whole Smith's view of the functions of government, we have postponed noticing his treatment of the physiocratic system, which occupies a part of his fourth book. He had formed the acquaintance of Quesnay, Turgot, and other members of their group during his sojourn in France in 1765, and would, as he told Dugald Stewart, had the patriarch of the school lived long enough, have dedicated to him the *Wealth of Nations*. He declares that, with all its imperfections, the system of Quesnay is "perhaps the nearest approximation to the truth that had yet appeared on the subject of political economy." Yet he seems not to be adequately conscious of the degree of coincidence between his own doctrines and those of the physiocrats. Dupont de Nemours complained that he did not do Quesnay the justice of recognizing him as his spiritual father. It is, however, alleged, on the other side, that already in 1753 Smith had been teaching as professor a body of economic doctrine the same in its broad features with that contained in his great work. This is indeed said by Stewart; and, though he gives no evidence of it, it is possibly quite true; if so, Smith's doctrinal descent must be traced rather from Hume than from the French school. The principal error of this school, that, namely, of representing agricultural labour as alone productive, he refutes in the fourth book, though in a manner which has not always been considered effective. Traces of the influence of their mistaken view appear to remain in his own work, as, for example, his assertion that in agriculture nature labours along with man, whilst in manufactures nature does nothing, man does all; and his distinction between productive and unproductive labour, which was doubtless suggested by their use of those epithets, and which seems to be inconsistent with his recognition of what is now called "personal capital." To

the same source McCulloch and others refer the origin of Smith's view, which they represent as an obvious error, that "individual advantage is not always a true test of the public advantage of different employments." But that view is really quite correct, as Prof. Nicholson has recently made plain. That the form taken by the use of capital, profits being given, is not indifferent to the working class as a whole even Ricardo admitted; and Cairnes, as we shall see, built on this consideration some of the most far-reaching conclusions in his *Leading Principles*.

On Smith's theory of taxation in his fifth book it is not necessary for us to dwell (see TAXATION). The well-known canons which he lays down as prescribing the essentials of a good system have been generally accepted. They have lately been severely criticized by Prof. Walker—of whose objections, however, there is only one which appears to be well-founded. Smith seems to favour the view that the contribution of the individual to public expenses may be regarded as payment for the services rendered to him by the state, and ought to be proportional to the extent of those services. If he held this opinion, which some of his expressions imply, he was certainly so far wrong in principle.

We shall not be held to anticipate unduly if we remark here on the way in which opinion, revolted by the aberrations of some of Smith's successors, has tended to turn from the disciples to the master. A strong sense of his comparative freedom from the vicious tendencies of Ricardo and his followers has recently prompted the suggestion that we ought now to recur to Smith, and take up once more from him the line of the economical succession. But notwithstanding his indisputable superiority, and whilst fully recognizing the great services rendered by his immortal work, we must not forget that, as has been already said, that work was, on the whole, a product, though an exceptionally eminent one, of the negative philosophy of the last century, resting largely in its ultimate foundation on metaphysical bases. The mind of Smith was mainly occupied with the work of criticism so urgent in his time; his principal task was to discredit and overthrow the economic system then prevalent, and to demonstrate the radical unfitness of the existing European Governments to direct the industrial movement. This office of his fell in with, and formed a part of, the general work of demolition carried on by the thinkers who gave to the 18th century its characteristic tone. It is to his honour that, besides this destructive operation, he contributed valuable elements to the preparation of an organic system of thought and of life. In his special domain he has not merely extinguished many errors and prejudices, and cleared the ground for truth, but has left us a permanent possession in the judicious analyses of economic facts and ideas, the wise practical suggestions, and the luminous indications of all kinds, with which his work abounds. Belonging to the best philosophical school of his period, that with which the names of Hume and Diderot are associated, he tended strongly towards the positive point of view. But it was not possible for him to attain it; and the final and fully normal treatment of the economic life of societies must be constituted on other and more lasting foundations than those which underlie his imposing construction.

It has been well said that of philosophic doctrines the saying "by their fruit ye shall know them" is eminently true. And it cannot be doubted that the germs of the true. And it cannot be doubted that the germs of the vicious methods and false or exaggerated theories of Smith's successors are to be found in his own work, though his good sense and practical bent prevented his following out his principles to their extreme consequences. The

objections of Hildebrand and others to the entire historical development of doctrine which the Germans designate as "Smithianismus" are regarded by those critics as applicable, not merely to his school as a whole, but, though in a less degree, to himself. The following are the most important of these objections. It is said—(1) Smith's conception of the social economy is essentially individualistic. In this he falls in with the general character of the negative philosophy of his age. That philosophy, in its most typical forms, even denied the natural existence of the disinterested affections, and explained the altruistic feelings as secondary results of self-love. Smith, however, like Hume, rejected these extreme views; and hence it has been held that in the *Wealth of Nations* he consciously, though tacitly, abstracted from the benevolent principles in human nature, and as a logical artifice supposed an "economic man" actuated by purely selfish motives. However this may be, he certainly places himself habitually at the point of view of the individual, whom he treats as a purely egoistic force, working uniformly in the direction of private gain, without regard to the good of others or of the community at large. (2) He justifies this personal attitude by its consequences, presenting the optimistic view that the good of the community is best attained through the free play of individual cupidities, provided only the law prevents the interference of one member of the society with the self-seeking action of another. He assumes with the negative school generally—though he has passages which are not in harmony with these propositions—that every one knows his true interest and will pursue it, and that the economic advantage of the individual coincides with that of the society. To this last conclusion he is secretly led, as we have seen, by *a priori* theological ideas, and also by metaphysical conceptions of a supposed system of nature, natural right, and natural liberty. (3) By this reduction of every question to one of individual gain, he is led to a too exclusive consideration of exchange value as distinct from wealth in the proper sense. This, whilst lending a mechanical facility in arriving at conclusions, gives a superficial character to economic investigation, divorcing it from the physical and biological sciences, excluding the question of real social utility, leaving no room for a criticism of production, and leading to a denial, like J. S. Mill's, of any economic doctrine dealing with consumption—in other words, with the use of wealth. (4) In condemning the existing industrial policy, he tends too much towards a glorification of non-government, and a repudiation of all social intervention for the regulation of economic life. (5) He does not keep in view the moral destination of our race, nor regard wealth as a means to the higher ends of life, and thus incurs, not altogether unjustly, the charge of materialism, in the wider sense of that word. Lastly, (6) his whole system is too absolute in its character; it does not sufficiently recognize the fact that, in the language of Hildebrand, man, as a member of society, is a child of civilization and a product of history, and that account ought to be taken of the different stages of social development as implying altered economic conditions and calling for altered economic action, or even involving a modification of the actor. Perhaps in all the respects here enumerated, certainly in some of them and notably in the last, Smith is less open to criticism than most of the later English economists; but it must, we think, be admitted that to the general principles which lie at the basis of his scheme the ultimate growth of these several vicious tendencies is traceable.

Great expectations had been entertained respecting Smith's work by competent judges before its publication, as is shown by the language of Ferguson on the subject in his *History of Civil Society*. That its merits received

prompt recognition is proved by the fact of six editions having been called for within the fifteen years after its appearance.<sup>1</sup> From the year 1783 it was more and more quoted in parliament. Pitt was greatly impressed by its reasonings; Smith is reported to have said that that minister understood the book as well as himself. Pulteney said in 1797 that Smith would convince the then living generation and would rule the next.

Smith's earliest critics were Bentham and Lauderdale, who, though in general agreement with him, differed on special points. Jeremy Bentham was author of a short treatise entitled *A Manual of Political Economy* (1843), and various economic monographs, the most celebrated of which was his *Defence of Usury* (1787). This contained (Letter xiii.) an elaborate criticism of a passage in the *Wealth of Nations*, already cited, in which Smith had approved of a legal maximum rate of interest fixed but a very little above the lowest market rate, as tending to throw the capital of the country into the hands of sober persons, as opposed to "prodigals and projectors." Smith is said to have admitted that Bentham had made out his case. He certainly argues it with great ability; and the true doctrine no doubt is that, in a developed industrial society, it is expedient to let the rate be fixed by contract between the lender and the borrower, the law interfering only in case of fraud.

Bentham's main significance does not belong to the economic field. But, on the one hand, what is known as Benthamism was undoubtedly, as Comte has said, a derivative from political economy, and in particular from the system of natural liberty; and, on the other, it promoted the temporary ascendancy of that system by extending to the whole of social and moral theory the use of the principle of individual interest and the method of deduction from that interest. This alliance between political economy and the scheme of Bentham is seen in the personal group of thinkers which formed itself round him,—thinkers most inaptly characterized by J. S. Mill as "profound," but certainly possessed of much acuteness and logical power, and tending, though vaguely, towards a positive sociology, which, from their want of genuinely scientific culture and their absolute and unhistorical modes of thought, they were incapable of founding.

Lord Lauderdale, in his *Inquiry into the Nature and Origin of Public Wealth* (1804), a book still worth reading, pointed out certain real weaknesses in Smith's account of value and the measure of value, and of the productivity of labour, and threw additional light on several subjects, such as the true mode of estimating the national income, and the reaction of the distribution of wealth on its production.

Smith stood just at the beginning of a great industrial revolution. The world of production and commerce in which he lived was still, as Cliffe Leslie has said, a "very

<sup>1</sup> Five editions of the *Wealth of Nations* appeared during the life of the author:—the second in 1779, the third in 1784, the fourth in 1786, and the fifth in 1789. After the third edition Smith made no change in the text of his work. The principal editions containing matter added by other economists are those by David Buchanan, with notes and an additional volume, 1814; by J. R. McCulloch, with life of the author, introductory discourse, notes, and supplemental dissertations, 1828 (also, with numerous additions, 1830; since reprinted several times with further additions); by the author of *England and America* Edward Gibbon Wakefield, with a commentary, which, however, is not continued beyond the second book, 1835-9; by James E. Thorold Rogers, now professor of political economy at Oxford, with biographical preface and a careful verification of all Smith's quotations and references, 1869 (2d ed., 1880); and by J. S. Nicholson, professor at Edinburgh, with notes referring to sources of further information on the various topics handled in the text, 1884. There is a careful *Abridgment* by W. P. Emerton (2d ed., 1881), founded on the earlier *Analysis* of Jeremiah Joyce (3d ed., 1821).

early" and comparatively narrow one; "the only steam-engine he refers to is Newcomen's," and the cotton trade is mentioned by him only once, and that incidentally. "Between the years 1760 and 1770," says Mr Marshall, "Roebuck began to smelt iron by coal, Brindley connected the rising seats of manufactures with the sea by canals, Wedgwood discovered the art of making earthenware cheaply and well, Hargreaves invented the spinning jenny, Arkwright utilized Wyatt's and High's inventions for spinning by rollers and applied water power to move them, and Watt invented the condensing steam-engine. Crompton's mule and Cartwright's powerloom came shortly after." Out of this rapid evolution followed a vast expansion of industry; but also many deplorable results, which, had Smith been able to foresee them, might have made him a less enthusiastic believer in the benefits to be wrought by the mere liberation of effort, and a less vehement denouncer of old institutions which in their day had given a partial protection to labour. Alongside of these evils of the new industrial system, socialism appeared as the alike inevitable and indispensable expression of the protest of the working classes and the aspiration after a better order of things; and what we now call "the social question," that inexorable problem of modern life, rose into the place which it has ever since maintained. This question was first effectually brought before the English mind by Thomas Robert Malthus (1766-1834), not, however, under the impulse of revolutionary sympathies, but in the interests of a conservative policy.

Malthus.

The first edition of the work which achieved this result appeared anonymously in 1798 under the title—*An Essay on the Principle of Population, as it affects the future improvement of Society, with remarks on the speculations of Mr Godwin, M. Condorcet, and other writers*. This book arose out of certain private controversies of its author with his father Daniel Malthus, who had been a friend of Rousseau, and was an ardent believer in the doctrine of human progress as preached by Condorcet and other French thinkers and by their English disciples. The most distinguished of the latter was William Godwin, whose *Enquiry concerning Political Justice* had been published in 1793. The views put forward in that work had been restated by its author in the *Enquirer* (1797), and it was on the essay in this volume entitled "Avarice and Profusion" that the discussion between the father and the son arose, "the general question of the future improvement of society" being thus raised between them—the elder Malthus defending the doctrines of Godwin, and the younger assailing them. The latter "sat down with an intention of merely stating his thoughts on paper in a clearer manner than he thought he could do in conversation," and the *Essay* on population was the result.

The social scheme of Godwin was founded on the idea that the evils of society arise from the vices of human institutions. There is more than enough of wealth available for all, but it is not equally shared: one has too much, another has little or nothing. Let this wealth, as well as the labour of producing it, be equally divided; then everyone will by moderate exertion obtain sufficient for plain living; there will be abundant leisure, which will be spent in intellectual and moral self-improvement; reason will determine human actions; government and every kind of force will be unnecessary; and, in time, by the peaceful influence of truth, perfection and happiness will be established on earth. To these glowing anticipations Malthus opposes the facts of the necessity of food, and the tendency of mankind to increase up to the limit of the available supply of it. In a state of universal physical wellbeing, this tendency, which in real life is held in check by the difficulty of procuring a subsistence, would

operate without restraint. Scarcity would follow the increase of numbers; the leisure would soon cease to exist; the old struggle for life would recommence; and inequality would reign once more. If Godwin's ideal system, therefore, could be established, the single force of the principle of population, Malthus maintained, would suffice to break it down.

It will be seen that the essay was written with a polemical object; it was an occasional pamphlet directed against the utopias of the day, not at all a systematic treatise on population suggested by a purely scientific interest. As a polemic, it was decidedly successful; it was no difficult task to dispose of the scheme of equality propounded by Godwin. Already, in 1761, Dr Robert Wallace had published a work (which was used by Malthus in the composition of his essay) entitled *Various Prospects of Mankind, Nature, and Providence*, in which, after speaking of a community of goods as a remedy for the ills of society, he confessed that he saw one fatal objection to such a social organization, namely, "the excessive population that would ensue." With Condorcet's extravagances, too, Malthus easily dealt. That eminent man, amidst the tempest of the French Revolution, had written, whilst in hiding from his enemies, his *Esquisse d'un tableau historique de l'esprit humain*. The general conception of this book makes its appearance an epoch in the history of the rise of sociology. In it, if we except some partial sketches by Turgot, is for the first time explained the idea of a theory of social dynamics founded on history; and its author is on this ground recognized by Comte as his principal immediate predecessor. But in the execution of his great project Condorcet failed. His negative metaphysics prevent his justly appreciating the past, and he indulges, at the close of his work, in vague hypotheses respecting the perfectibility of our race, and in irrational expectations of an indefinite extension of the duration of human life. Malthus seems to have little sense of the nobleness of Condorcet's attitude, and no appreciation of the grandeur of his leading idea. But of his chimerical hopes he is able to make short work; his good sense, if somewhat limited and prosaic, is at least effectual in detecting and exposing utopias.

The project of a formal and detailed treatise on population was an afterthought of Malthus. The essay in which he had studied a hypothetic future led him to examine the effects of the principle he had put forward on the past and present state of society; and he undertook an historical examination of these effects, and sought to draw such inferences in relation to the actual state of things as experience seemed to warrant. The consequence of this was such a change in the nature and composition of the essay as made it, in his own language, "a new work." The book, so altered, appeared in 1803 under the title—*An Essay on the Principle of Population, or a view of its Past and Present Effects on Human Happiness; with an Enquiry into our prospects respecting the future removal or mitigation of the evils which it occasions*.

In the original form of the essay he had spoken of no checks to population but those which came under the head either of vice or of misery. He now introduces the new element of the preventive check supplied by what he calls "moral restraint," and is thus enabled to "soften some of the harshest conclusions" at which he had before arrived. The treatise passed through six editions in his lifetime, and in all of them he introduced various additions and corrections. That of 1816 is the last he revised, and supplies the final text from which it has since been reprinted.

Notwithstanding the great development which he gave to his work and the almost unprecedented amount of

discussion to which it gave rise, it remains a matter of some difficulty to discover what solid contribution he has made to our knowledge, nor is it easy to ascertain precisely what practical precepts, not already familiar, he founded on his theoretic principles. This twofold vagueness is well brought out in his celebrated correspondence with Senior, in the course of which it seems to be made apparent that his doctrine is new not so much in its essence as in the phraseology in which it is couched. He himself tells us that when, after the publication of the original essay, the main argument of which he had deduced from Hume, Wallace, Smith, and Prie, he began to inquire more closely into the subject, he found that "much more had been done" upon it "than he had been aware of." It had "been treated in such a manner by some of the French economists, occasionally by Montesquieu, and, among our own writers, by Dr Franklin, Sir James Steuart, Mr Arthur Young, and Mr Townsend, as to create a natural surprise that it had not excited more of the public attention." "Much, however," he thought, "remained yet to be done. The comparison between the increase of population and food had not, perhaps, been stated with sufficient force and precision," and "few inquiries had been made into the various modes by which the level" between population and the means of subsistence "is effected." The first desideratum here mentioned—the want, namely, of an accurate statement of the relation between the increase of population and food—Malthus doubtless supposed to have been supplied by the celebrated proposition that "population increases in a geometrical, food in an arithmetical ratio." This proposition, however, has been conclusively shown to be erroneous, there being no such difference of law between the increase of man and that of the organic beings which form his food. J. S. Mill is indignant with those who criticize Malthus's formula, which he groundlessly describes as a mere "passing remark," because, as he thinks, though erroneous, it sufficiently suggests what is true; but it is surely important to detect unreal science, and to test strictly the foundations of beliefs. When the formula which we have cited is not used, other somewhat nebulous expressions are sometimes employed, as, for example, that "population has a tendency to increase faster than food," a sentence in which both are treated as if they were spontaneous growths, and which, on account of the ambiguity of the word "tendency," is admittedly consistent with the fact asserted by Senior, that food tends to increase faster than population. It must always have been perfectly well known that population will probably (though not necessarily) increase with every augmentation of the supply of subsistence, and may, in some instances, inconveniently press upon, or even for a certain time exceed, the number properly corresponding to that supply. Nor could it ever have been doubted that war, disease, poverty—the last two often the consequences of vice—are causes which keep population down. In fact, the way in which abundance, increase of numbers, want, increase of deaths, succeed each other in the natural economy, when reason does not intervene, had been fully explained by the Rev. Joseph Townsend in his *Dissertation on the Poor Laws* (1786), which was known to Malthus. Again, it is surely plain enough that the apprehension by individuals of the evils of poverty, or a sense of duty to their possible offspring, may retard the increase of population, and has in all civilized communities operated to a certain extent in that way. It is only when such obvious truths are clothed in the technical terminology of "positive" "preventive checks" that they appear novel and profound; and yet they appear to contain the whole message of Malthus to mankind. The laborious apparatus of historical and statistical facts

respecting the several countries of the globe, adduced in the altered form of the essay, though it contains a good deal that is curious and interesting, establishes no general result which was not previously well known, and is accordingly ignored by James Mill and others, who rest the theory on facts patent to universal observation. Indeed, as we have seen, the entire historical inquiry was an afterthought of Malthus, who, before entering on it, had already announced his fundamental principle.

It would seem, then, that what has been ambitiously called Malthus's theory of population, instead of being a great discovery, as some have represented it, or a poisonous novelty, as others have considered it, is no more than a formal enunciation of obvious, though sometimes neglected, facts. The pretentious language often applied to it by economists is objectionable, as being apt to make us forget that the whole subject with which it deals is as yet very imperfectly understood—the causes which modify the force of the sexual instinct, and those which lead to variations in fecundity, still awaiting a complete investigation.

It is the law of diminishing returns from land (of which we shall hear more hereafter), involving as it does—though only hypothetically—the prospect of a continuously increasing difficulty in obtaining the necessary sustenance for all the members of a society, that gives the principal importance to population as an economic factor. It is, in fact, the confluence of the Malthusian ideas with the theories of Ricardo, especially with the corollaries which the latter, as we shall see, deduced from the doctrine of rent (though these were not accepted by Malthus), that has led to the introduction of population as an element in the discussion of so many economic questions in recent times.

Malthus had undoubtedly the great merit of having called public attention in a striking and impressive way to a subject which had neither theoretically nor practically been sufficiently considered. But he and his followers appear to have greatly exaggerated both the magnitude and the urgency of the dangers to which they pointed.<sup>1</sup> In their conceptions a single social imperfection assumed such portentous dimensions that it seemed to overcloud the whole heaven and threaten the world with ruin. This doubtless arose from his having at first omitted altogether from his view of the question the great counteracting agency of moral restraint. Because a force exists, capable, if unchecked, of producing certain results, it does not follow that those results are imminent or even possible in the sphere of experience. A body thrown from the hand would, under the single impulse of projection, move for ever in a straight line; but it would not be reasonable to take special action for the prevention of this result, ignoring the fact that it will be sufficiently counteracted by the other forces which will come into play. And such other forces exist in the case we are considering. If the inherent energy of the principle of population (supposed everywhere the same) is measured by the rate at which numbers increase under the most favourable circumstances, surely the force of less favourable circumstances, acting through prudential or altruistic motives, is measured by the great difference between this maximum rate and those which are observed to prevail in most European countries. Under a rational system of institutions, the adaptation of numbers to the means available for their support is effected by the felt or anticipated pressure of circumstances and the fear of social degradation, within a tolerable degree of approximation to what is desirable. To bring the result nearer to the just standard, a higher measure of

<sup>1</sup> Malthus himself said, "It is probable that, having found the bow bent too much one way, I was induced to bend it too much the other in order to make it straight."

popular enlightenment and more serious habits of moral reflexion ought indeed to be encouraged. But it is the duty of the individual to his possible offspring, and not any vague notions as to the pressure of the national population on subsistence, that will be adequate to influence conduct.

The only obligation on which Malthus insists is that of abstinence from marriage so long as the necessary provision for a family has not been acquired or cannot be reasonably anticipated. The idea of post-nuptial continence, which has since been put forward by J. S. Mill and others, is foreign to his view. He even suggests that an allowance might be made from the public funds for every child in a family beyond the number of six, on the ground that, when a man marries, he cannot tell how many children he shall have, and that the relief from an unlooked-for distress afforded by such a grant would not operate as an encouragement to marriage. The duty of economic prudence in entering on the married state is plain; but in the case of working men the idea of a secured provision must not be unduly pressed, and it must also be remembered that the proper age for marriage in any class depends on the duration of life in that class. Too early marriages, however, are certainly not unfrequent, and they are attended with other than material evils, so that possibly even legal measures might with advantage be resorted to for preventing them in all ranks by somewhat postponing the age of full civil competence. On the other hand, however, the Malthusians often speak too lightly of involuntary celibacy, not recognizing sufficiently that it is a deplorable necessity. They do not adequately estimate the value of domestic life as a school of the civic virtues, and the social importance (even apart from personal happiness) of the mutual affective education arising from the relations of the sexes in a well-constituted union.

Malthus further infers from his principles that states should not artificially stimulate population, and in particular that poor-laws should not be established, and, where they exist, should be abolished. The first part of this proposition cannot be accepted as applying to every social phase, for it is evident that in a case like that of ancient Rome, where continuous conquest was the chief occupation of the national activity, or in other periods when protracted wars threatened the independence or security of nations, statesmen might wisely take special action of the kind deprecated by Malthus. In relation to modern industrial communities he is doubtless in general right, though the promotion of immigration in new states is similar in principle to the encouragement of population. The question of poor-laws involves other considerations. The English system of his day was certainly a vicious one, though acting in some degree as a corrective of other evils in our social institutions; and efforts for its amendment tended to the public good. But the proposal of abolition is one from which statesmen have recoiled, and which general opinion has never adopted. It is difficult to believe that the present system will be permanent; it is too mechanical and undiscriminating; on some sides too lax, it is often unduly rigorous in the treatment of the worthy poor who are the victims of misfortune; and, in its ordinary modes of dealing with the young, it is open to grave objection. But it would certainly be rash to abolish it; it is one of several institutions which will more wisely be retained until the whole subject of the life of the working classes has been more thoroughly, and also more sympathetically, studied. The position of Malthus with respect to the relief of destitution is subject to this general criticism that, first proving too much, he then shrinks from the consequences of his own logic. It follows from his arguments, and is indeed explicitly stated in a celebrated passage of his original essay, that he who has brought children into the world without adequate provision for them should be left to the punishment of Nature, that "it is a miserable ambition to wish to snatch the rod from her hand," and to defeat the action of her laws, which are the laws of God, and which "have doomed him and his family to suffer." Though his theory leads him to this conclusion, he could not, as a Christian clergyman, maintain the doctrine that, seeing our brother in need, we ought to shut up our bowels of compassion from him; and thus he is involved in the radical inconsequence of admitting the lawfulness, if not the duty, of relieving distress, whilst he yet must regard the act as doing mischief to society. Buckle, who was imposed on by more than one of the exaggerations of the economists, accepts the logical inference which Malthus evaded. He alleges that the only ground on which we are justified in relieving destitution is the essentially self-regarding one, that by remaining deaf to the appeal of the sufferer we should probably blunt the edge of our own finer sensibilities.

It can scarcely be doubted that the favour which was at once accorded to the views of Malthus in certain circles was due in part to an impression, very welcome to the higher ranks of society, that they tended to relieve the rich and powerful of responsibility for the condition of the working classes, by showing that the latter had chiefly

themselves to blame, and not either the negligence of their superiors or the institutions of the country. The application of his doctrines, too, made by some of his successors had the effect of discouraging all active effort for social improvement. Thus Chalmers "reviews *seriatim* and gravely sets aside all the schemes usually proposed for the amelioration of the economic condition of the people" on the ground that an increase of comfort will lead to an increase of numbers, and so the last state of things will be worse than the first.

Malthus has in more recent times derived a certain degree of reflected lustre from the rise and wide acceptance of the Darwinian hypothesis. Its author himself, in tracing its filiation, points to the phrase "struggle for existence" used by Malthus in relation to the social competition. Darwin believes that man has advanced to his present high condition through such a struggle, consequent on his rapid multiplication. He regards, it is true, the agency of this cause for the improvement of our race as largely superseded by moral influences in the more advanced social stages. Yet he considers it, even in these stages, of so much importance towards that end that, notwithstanding the individual suffering arising from the struggle for life, he deprecates any great reduction in the natural, by which he seems to mean the ordinary, rate of increase.

There has been of late exhibited in some quarters a tendency to apply the doctrine of the "survival of the fittest" to human society in such a way as to intensify the harsher features of Malthus's exposition by encouraging the idea that whatever cannot sustain itself is fated, and must be allowed, to disappear. But what is repellent in this conception is removed by a wider view of the influence of Humanity, as the presiding race, alike on vital and on social conditions. As in the general animal domain the supremacy of man introduces a new force consciously controlling and ultimately determining the destinies of the subordinate species, so human providence in the social sphere can intervene for the protection of the weak, modifying by its deliberate action what would otherwise be a mere contest of comparative strengths inspired by selfish instincts.

David Ricardo (1772-1823) is essentially of the school of Smith, whose doctrines he in the main accepts, whilst he seeks to develop them, and to correct them in certain particulars. But his mode of treatment is very different from Smith's. The latter aims at keeping close to the realities of life as he finds them,—at representing the conditions and relations of men and things as they are; and, as Hume remarked on first reading his great work, his principles are everywhere exemplified and illustrated with curious facts. Quite unlike this is the way in which Ricardo proceeds. He moves in a world of abstractions. He sets out from more or less arbitrary assumptions, reasons deductively from these, and announces his conclusions as true, without allowing for the partial unreality of the conditions assumed or confronting his results with experience. When he seeks to illustrate his doctrines, it is from hypothetical cases,—his favourite device being that of imagining two contracting savages, and considering how they would be likely to act. He does not explain—probably he had not systematically examined, perhaps was not competent to examine—the appropriate method of political economy; and the theoretic defence of his mode of proceeding was left to be elaborated by J. S. Mill and Cairnes. But his example had a great effect in determining the practice of his successors. There was something highly attractive to the ambitious theorist in the sweeping march of logic which seemed in Ricardo's hands to emulate the certainty and comprehensiveness of mathematical

proof, and in the portable and pregnant formulæ which were so convenient in argument, and gave a prompt, if often a more apparent than real, solution of difficult problems. Whatever there was of false or narrow in the fundamental positions of Smith had been in a great degree corrected by his practical sense and strong instinct for reality, but was brought out in its full dimensions and even exaggerated in the abstract theorems of Ricardo and his followers.

The dangers inherent in his method were aggravated by the extreme looseness of his phraseology. Senior pronounces him "the most incorrect writer who ever attained philosophical eminence." His most ardent admirers find him fluctuating and uncertain in the use of words, and generally trace his errors to a confusion between the ordinary employment of a term and some special application of it which he has himself devised.

The most complete exposition of his system is to be found in his *Principles of Political Economy and Taxation* (1817). This work is not a complete treatise on the science, but a rather loosely connected series of disquisitions on value and price, rent, wages and profits, taxes, trade, money and banking. Yet, though the connexion of the parts is loose, the same fundamental ideas recur continually, and determine the character of the entire scheme.

The principal problem to which he addresses himself in this work is that of distribution,—that is to say, the proportions of the whole produce of the country which will be allotted to the proprietor of land, to the capitalist, and to the labourer. And it is important to observe that it is especially the variations in their respective portions which take place in the progress of society that he professes to study,—one of the most unhistorical of writers thus indicating a sense of the necessity of a doctrine of economic dynamics—a doctrine which, from his point of view, it was impossible to supply.

The principle which he puts first in order, and which is indeed the key to the whole, is this—that the exchange value of any commodity the supply of which can be increased at will is regulated, under a régime of free competition, by the labour necessary for its production. Similar propositions are to be found in the *Wealth of Nations*, not to speak of earlier English writings. Smith had said that, "in the early and rude state of society which precedes both the accumulation of stock and the appropriation of land, the proportion between the quantities of labour necessary for acquiring different objects seems to be the only circumstance which can afford any rule for exchanging them with one another." But he wavers in his conception, and presents as the measure of value sometimes the quantity of labour necessary for the production of the object, sometimes the quantity of labour which the object would command in the market, which are identical only for a given time and place. The theorem requires correction for a developed social system by the introduction of the consideration of capital, and takes the form in which it is elsewhere quoted from Malthus by Ricardo, that the real price of a commodity "depends on the greater or less quantity of capital and labour which must be employed to produce it." (The expression "quantity of capital" is lax, the element of time being omitted, but the meaning is obvious). Ricardo, however, constantly takes no notice of capital, mentioning labour alone in his statement of this principle, and seeks to justify his practice by treating capital as "accumulated labour"; but this artificial way of viewing the facts obscures the nature of the co-operation of capital in production, and by keeping the necessity of this co-operation out of sight has encouraged some socialistic errors. Ricardo does not sufficiently distinguish between the cause or determinant and the measure of value; nor does he carry back the principle of cost of production as regulator of value to its foundation in the effect of that cost on the limitation of supply. It is the "natural price" of a commodity that is fixed by the theorem we have stated; the market price will be subject to accidental and temporary variations from this standard, depending on changes in demand and supply; but the price will, permanently and in the long run, depend on cost of production defined as above. On this basis Ricardo goes on to explain the laws according to which the produce of the land and the labour of the country is distributed amongst the several classes which take part in production.

The theory of rent, with which he begins, though commonly associated with his name, and though it certainly forms the most

vital part of his general economic scheme, was not really his, nor did he lay claim to it. He distinctly states in the preface to the *Principles*, that "in 1815 Mr Malthus, in his *Inquiry into the Nature and Progress of Rent*, and a fellow of University College, Oxford, in his *Essay on the Application of Capital to Land*, presented to the world, nearly at the same moment, the true doctrine of rent." The second writer here referred to was Sir Edward West, afterwards a judge of the supreme court of Bombay. Still earlier than the time of Malthus and West, as McCulloch has pointed out, this doctrine had been clearly conceived and fully stated by Dr James Anderson in his *Enquiry into the Nature of Corn-Laws*, published at Edinburgh in 1777. That this tract was unknown to Malthus and West we have every reason to believe; but the theory is certainly as distinctly enunciated and as satisfactorily supported in it as in their treatises; and the whole way in which it is put forward by Anderson strikingly resembles the form in which it is presented by Ricardo.

The essence of the theory is that rent, being the price paid by the cultivator to the owner of land for the use of its productive powers, is equal to the excess of the price of the produce of the land over the cost of production on that land. With the increase of population, and therefore of demand for food, inferior soils will be taken into cultivation; and the price of the entire supply necessary for the community will be regulated by the cost of production of that portion of the supply which is produced at the greatest expense. But for the land which will barely repay the cost of cultivation no rent will be paid. Hence the rent of any quality of land will be equal to the difference between the cost of production on that land and the cost of production of that produce which is raised at the greatest expense.

The doctrine is perhaps most easily apprehended by means of the supposition here made of the coexistence in a country of a series of soils of different degrees of fertility which are successively taken into cultivation as population increases. But it would be an error to believe, though Ricardo sometimes seems to imply it, that such difference is a necessary condition of the existence of rent. If all the land of a country were of equal fertility, still if it were appropriated, and if the price of the produce were more than an equivalent for the labour and capital applied to its production, rent would be paid. This imaginary case, however, after using it to clear our conceptions, we may for the future leave out of account.

The price of produce being, as we have said, regulated by the cost of production of that which pays no rent, it is evident that "corn is not high because a rent is paid, but a rent is paid because corn is high," and that "no reduction would take place in the price of corn although landlords should forego the whole of their rent." Rent is, in fact, no determining element of price; it is paid, indeed, out of the price, but the price would be the same if no rent were paid, and the whole price were retained by the cultivator.

It has often been doubted whether or not Adam Smith held this theory of rent. Sometimes he uses language which seems to imply it, and states propositions which, if developed, would infallibly lead to it. Thus he says, in a passage already quoted, "such parts only of the produce of land can commonly be brought to market of which the ordinary price is sufficient to replace the stock which must be employed in bringing them thither, together with its ordinary profits. If the ordinary price is more than this, the surplus part of it will naturally go to the rent of land. If it is not more, though the commodity can be brought to market, it can afford no rent to the landlord. Whether the price is or is not more depends on the demand." Again, in Smith's application of these considerations to mines, "the whole principle of rent," Ricardo tells us, "is admirably and perspicuously explained." But he had formed the opinion that there is in fact no land which does not afford a rent to the landlord; and, strangely, he seems not to have seen that this appearance might arise from the aggregation into an economic whole of parcels of land which can and others which cannot pay rent. The truth, indeed, is that the fact, if it were a fact, that all the land in a country pays rent would be irrelevant as an argument against the Andersonian theory, for it is the same thing in substance if there be any capital employed on land already cultivated which yields a return no more than equal to ordinary profits. Such last-employed capital cannot afford rent at the existing rate of profit, unless the price of produce should rise.

The belief which some have entertained that Smith, notwithstanding some vague or inaccurate expressions, really held the Andersonian doctrine, can scarcely be maintained when we remember that Hume, writing to him after having read for the first time the *Wealth of Nations*, whilst expressing general agreement with his opinions, said (apparently with reference to bk. I. chap. vii.), "I cannot think that the rent of farms makes any part of the price of the produce, but that the price is determined altogether by the quantity and the demand." It is further noteworthy that a statement of the theory of rent is given in the same volume, published in 1777, which contains Anderson's polemic against Smith's objections to a bounty on the exportation of corn; this volume can hardly have escaped Smith's notice, yet neither by its contents nor

by Hume's letter was he led to modify what he had said in his first edition on the subject of rent.

It must be remembered that not merely the unequal fertilities of different soils will determine differences of rent; the more or less advantageous situation of a farm in relation to markets, and therefore to roads and railways, will have a similar effect. Every diminution of the cost of transit will enable the produce to be brought to market at a smaller expense, and will thus increase the surplus which constitutes rent. This consideration is indicated by Ricardo, though he does not give it prominence, but dwells mainly on the comparative productiveness of soils.

Rent is defined by Ricardo as the price paid for the use of "the original and indestructible powers of the soil." He thus differentiates rent, as he uses the term, from what is popularly designated by the word; and, when it is to be taken in his sense, it is often qualified as the "true" or "economic" rent. Part of what is paid to the landlord is often really profit on his expenditure in preparing the farm for cultivation by the tenant. But it is to be borne in mind that wherever such improvements are "amalgamated with the land," and "add permanently to its productive powers," the return for them follows the laws, not of profit, but of rent. Hence it becomes difficult, if not impossible, in practice to discriminate with any degree of accuracy the amount received by the landlord "for the use of the original powers of the soil" from the amount received by him as remuneration for his improvements or those made by his predecessors. These have raised the farm, as an instrument for producing food, from one class of productiveness to a higher, and the case is the same as if nature had originally placed the land in question in that higher class.

Smith had treated it as the peculiar privilege of agriculture, as compared with other forms of production, that in it "nature labours along with man," and therefore, whilst the workmen in manufactures occasion the reproduction merely of the capital which employs them with its owner's profits, the agricultural labourer occasions the reproduction, not only of the employer's capital with profits, but also of the rent of the landlord. This last he viewed as the free gift of nature which remained "after deducting or compensating everything which can be regarded as the work of man." Ricardo justly observes in reply that "there is not a manufacture which can be mentioned in which nature does not give her assistance to man." He then goes on to quote from Buchanan the remark that "the notion of agriculture yielding a produce and a rent in consequence, because nature concurs with industry in the process of cultivation, is a mere fancy. It is not from the produce, but from the price at which the produce is sold, that the rent is derived; and this price is got, not because nature assists in the production, but because it is the price which suits the consumption to the supply."<sup>1</sup> There is no gain to the society at large from the rise of rent; it is advantageous to the landlords alone, and their interests are thus permanently in opposition to those of all other classes. The rise of rent may be retarded, or prevented, or even temporarily changed to a fall, by agricultural improvements, such as the introduction of new manures or of machines or of a better organization of labour (though there is not so much room for this last as in other branches of production), or the opening of new sources of supply in foreign countries; but the tendency to a rise is constant so long as the population increases.

The great importance of the theory of rent in Ricardo's system arises from the fact that he makes the general economic condition of the society to depend altogether on the position in which agricultural exploitation stands. This will be seen from the following statement of his theory of wages and profits. The produce of every expenditure of labour and capital being divided between the labourer and the capitalist, in proportion as one obtains more the other will necessarily obtain less. The productiveness of labour being given, nothing can diminish profit but a rise of wages, or increase it but a fall of wages. Now the price of labour, being the same as its cost of production, is determined by the price of the commodities necessary for the support of the labourer. The price of such manufactured articles as he requires has a constant tendency to fall, principally by reason of the progressive application of the division of labour to their production. But the cost of his maintenance essentially depends, not on the price of those articles, but on that of his food; and, as the production of food will in the progress of society and of population require the sacrifice of more and more labour, its price will rise; money wages will consequently rise, and with the rise of wages profits will fall. Thus it is to the necessary gradual descent to inferior soils, or less productive expenditure on the same soil, that the decrease in the rate of profit which has historically taken place is to be attributed (Smith ascribed this decrease to the competition of capitalists, though in

one place, book I. chap. ix., he had a glimpse of the Ricardian view). This gravitation of profits towards a minimum is happily checked at times by improvements of the machinery employed in the production of necessities, and especially by such discoveries in agriculture and other causes as reduce the cost of the prime necessary of the labourer; but, here again, the tendency is constant. Whilst the capitalist thus loses, the labourer does not gain; his increased money wages only enable him to pay the increased price of his necessities, of which he will have no greater and probably a less share than he had before. In fact, the labourer can never for any considerable time earn more than what is required to enable the class to subsist in such a degree of comfort as custom has made indispensable to them, and to perpetuate their race without either increase or diminution. That is the "natural" price of labour; and if the market rate temporarily rises above it population will be stimulated, and the rate of wages will again fall. Thus, whilst rent has a constant tendency to rise and profit to fall, the rise or fall of wages will depend on the rate of increase of the working classes. For the improvement of their condition Ricardo thus has to fall back on the Malthusian remedy, of the effective application of which he does not, however, seem to have much expectation. The securities against a superabundant population to which he points are the gradual abolition of the poor laws—for their amendment would not content him—and the development amongst the working classes of a taste for greater comforts and enjoyments.

It will be seen that the socialists have somewhat exaggerated in announcing, as Ricardo's "iron law" of wages, their absolute identity with the amount necessary to sustain the existence of the labourer and enable him to continue the race. He recognizes the influence of a "standard of living" as limiting the increase of the numbers of the working classes, and so keeping their wages above the lowest point. But he also holds that, in long-settled countries, in the ordinary course of human affairs, and in the absence of special efforts restricting the growth of population, the condition of the labourer will decline as surely, and from the same causes, as that of the landlord will be improved.

If we are asked whether this doctrine of rent, and the consequences which Ricardo deduced from it, are true, we must answer that they are hypothetically true in the most advanced industrial communities, and there only (though they have been rashly applied to the cases of India and Ireland), but that even in those communities neither safe inference nor sound action can be built upon them. As we shall see hereafter, the value of most of the theorems of the classical economics is a good deal attenuated by the habitual assumptions that we are dealing with "economic men," actuated by one principle only; that custom, as against competition, has no existence; that there is no such thing as combination; that there is equality of contract between the parties to each transaction, and that there is a definite universal rate of profit and wages in a community, which implies that the capital embarked in any undertaking will pass at once to another in which larger profits are for the time to be made; that a labourer, whatever his local ties of feeling, family, habit, or other engagements, will transfer himself immediately to any place where, or employment in which, for the time, larger wages are to be earned than those he had previously obtained; and that both capitalists and labourers have a perfect knowledge of the condition and prospects of industry throughout the country, both in their own and other occupations. But in Ricardo's speculations on rent and its consequences there is still more of abstraction. The influence of emigration, which has assumed vast dimensions since his time, is left out of account, and the amount of land at the disposal of a community is supposed limited to its own territory, whilst contemporary Europe is in fact largely fed by the western States of America. He did not adequately appreciate the degree in which the augmented productiveness of labour, whether from increased intelligence, improved organization, introduction of machinery, or more rapid and cheaper communication, steadily keeps down the cost of production. To these influences must be added those of legal reforms in tenure, and fairer conditions in contracts, which operate in the same direction. As a result of all these causes, the pressure anticipated by Ricardo is not felt, and the cry is rather of the landlords over falling rents than of the consumer over rising prices. The entire conditions are in fact so altered that Prof. Nicholson, no enemy to the "orthodox" economics, when recently conducting an inquiry into the present state of the agricultural question, pronounced the so-called Ricardian theory of rent "too abstract to be of practical utility."

A particular economic subject on which Ricardo has thrown a useful light is the nature of the advantages derived from foreign commerce, and the conditions under which such commerce can go on. Whilst preceding writers had represented those benefits as consisting in affording a vent for surplus produce, or enabling a portion of the national capital to replace itself with a profit, he pointed out that they consist "simply and solely in this, that it enables each nation to obtain, with a given amount of labour and capital, a greater quantity of all commodities taken together." This is no doubt the point of view at which we should habitually

<sup>1</sup> Senior, however, has pointed out that Smith is partly right; whilst it is true that rent is demanded because the productive powers of nature are limited, and increased population requires a less remunerative expenditure in order to obtain the necessary supply, on the other hand, it is the power which most land possesses of producing the subsistence of more persons than are required for its cultivation that supplies the fund out of which rent can be paid.

place ourselves; but the other forms of expression employed by his predecessors are sometimes useful as representing real considerations affecting national production, and need not be absolutely disused. Ricardo proceeds to show that what determines the purchase of any commodity from a foreign country is not the circumstance that it can be produced there with less labour and capital than at home. If we have a greater positive advantage in the production of some other article than in that of the commodity in question, even though we have an advantage in producing the latter, it may be our interest to devote ourselves to the production of that in which we have the greatest advantage, and to import that in producing which we should have a less, though a real, advantage. It is, in short, not absolute cost of production, but comparative cost, which determines the interchange. This remark is just and interesting, though an undue importance seems to be attributed to it by J. S. Mill and Cairnes, the latter of whom magniloquently describes it as "sounding the depths" of the problem of international dealings,—though, as we shall see hereafter, he modifies it by the introduction of certain considerations respecting the conditions of domestic production.

For the nation as a whole, according to Ricardo, it is not the gross produce of the land and labour, as Smith seems to assert, that is of importance, but the net income—the excess, that is, of this produce over the cost of production, or, in other words, the amount of its rent and its profits; for the wages of labour, not essentially exceeding the maintenance of the labourers, are by him considered only as a part of the "necessary expenses of production." Hence it follows, as he himself in a characteristic and often quoted passage says, that, "provided the net real income of the nation be the same, it is of no importance whether it consists of ten or twelve millions of inhabitants. If five millions of men could produce as much food and clothing as was necessary for ten millions, food and clothing for five millions would be the net revenue. Would it be of any advantage to the country that to produce this same net revenue seven millions of men should be required,—that is to say, that seven millions should be employed to produce food and clothing sufficient for twelve millions? The food and clothing of five millions would be still the net revenue. The employing a greater number of men would enable us neither to add a man to our army and navy nor to contribute one guinea more in taxes." Industry is here viewed, just as by the mercantilists, in relation to the military and political power of the state, not to the maintenance and improvement of human beings, as its end and aim. The labourer, as Held has remarked, is regarded not as a member of society, but as a means to the ends of society, on whose sustenance a part of the gross income must be expended, as another part must be spent on the sustenance of horses. We may well ask, as Sismondi did in a personal interview with Ricardo, "What! is wealth then everything? are men absolutely nothing?"

On the whole what seems to us true of Ricardo is this, that, whilst he had remarkable powers, they were not the powers best fitted for sociological research. Nature intended him rather for a mathematician of the second order than for a social philosopher. Nor had he the due previous preparation for social studies; for we must decline to accept Bagehot's idea that, though "in no high sense an educated man," he had a specially apt training for such studies in his practice as an eminently successful stockjobber. The same writer justly notices the "anxious penetration with which he follows out rarefied minutiae." But he wanted breadth of survey, a comprehensive view of human nature and human life, and the strong social sympathies which, as the greatest minds have recognized, are a most valuable aid in this department of study. On a subject like that of money, where a few elementary propositions—into which no moral ingredient enters—have alone to be kept in view, he was well adapted to succeed; but in the larger social field he is at fault. He had great deductive readiness and skill (though his logical accuracy, as Mr Sidgwick remarks, has been greatly exaggerated). But in human affairs phenomena are so complex, and principles so constantly limit or even compensate one another, that rapidity and daring in deduction may be the greatest of dangers, if they are divorced from a wide and balanced appreciation of facts. Dialectic ability is, no doubt, a valuable gift, but the first condition for success in social investigation is to see things as they are.

A sort of Ricardo-myths for some time existed in economic circles. It cannot be doubted that the exaggerated

estimate of his merits arose in part from a sense of the support his system gave to the manufacturers and other capitalists in their growing antagonism to the old aristocracy of landowners. The same tendency, as well as his affinity to their too abstract and unhistorical modes of thought, and their eudæmonistic doctrines, recommended him to the Benthamite group, and to the so-called Philosophical Radicals generally. Brougham said he seemed to have dropped from heaven—a singular avatar, it must be owned. His real services in connexion with questions of currency and banking naturally created a prepossession in favour of his more general views. But, apart from those special subjects, it does not appear that, either in the form of solid theoretic teaching or of valuable practical guidance, he has really done much for the world, whilst he admittedly misled opinion on several important questions. De Quincey's presentation of him as a great revealer of truth is now seen to be an extravagance. J. S. Mill and others speak of his "superior lights" as compared with those of Adam Smith; but his work, as a contribution to our knowledge of human society, will not bear a moment's comparison with the *Wealth of Nations*.

It is interesting to observe that Malthus, though the combination of his doctrine of population with the principles of Ricardo composed the creed for some time professed by all the "orthodox" economists, did not himself accept the Ricardian scheme. He prophesied that "the main part of the structure would not stand." "The theory," he says, "takes a partial view of the subject, like the system of the French economists; and, like that system, after having drawn into its vortex a great number of very clever men, it will be unable to support itself against the testimony of obvious facts, and the weight of those theories which, though less simple and captivating, are more just, on account of their embracing more of the causes which are in actual operation in all economical results."

We saw that the foundations of Smith's doctrine in general philosophy were unsound, and the ethical character of his scheme in consequence injuriously affected; but his method, consisting in a judicious combination of induction and deduction, we found (so far as the statical study of economic laws is concerned) little open to objection. Mainly through the influence of Ricardo, economic method was perverted. The science was led into the mistaken course of turning its back on observation, and seeking to evolve the laws of phenomena out of a few hasty generalizations by a play of logic. The principal vices which have been in recent times not unjustly attributed to the members of the "orthodox" school were all encouraged by his example, namely,—(1) the viciously abstract character of the conceptions with which they deal, (2) the abusive preponderance of deduction in their processes of research, and (3) the too absolute way in which their conclusions are conceived and enunciated.

The two works of Malthus already named are by far the most important in the history of the science. He was also author of *Principles of Political Economy* (1820), *Definitions in Political Economy*, and some minor pieces. The works of Ricardo have been collected in one volume, with a biographical notice, by J. R. McCulloch (1846).

After Malthus and Ricardo, the first of whom had fixed the public attention irresistibly on certain aspects of society, Epigoni. and the second had led economic research into new, if questionable, paths, came a number of minor writers who were mainly their expositors and commentators, and whom, accordingly, the Germans, with allusion to Greek mythical history, designate as the Epigoni. By them the doctrines of Smith and his earliest successors were thrown into more systematic shape, limited and guarded so as to

be less open to criticism, couched in a more accurate terminology, modified in subordinate particulars, or applied to the solution of the practical questions of their day.

- James Mill. James Mill's *Elements* (1821) deserves special notice, as exhibiting the system of Ricardo with a thorough-going rigour, a compactness of presentation, and a skill in the disposition of materials, which give to it in some degree the character of a work of art. The *a priori* political economy is here reduced to its simplest expression.
- M'Culloch. J. R. M'Culloch (1789-1854), author of a number of laborious statistical and other compilations, criticized current economic legislation in the *Edinburgh Review* from the point of view of the Ricardian doctrine, taking up substantially the same theoretic position as was occupied at a somewhat later period by the Manchester school. He is altogether without originality, and never exhibits any philosophic elevation or breadth. His confident dogmatism is often repellent; he admitted in his later years that he had been too fond of novel opinions, and defended them with more heat and pertinacity than they deserved. It is noticeable that, though often spoken of in his own time both by those who agreed with his views, and those, like Sismondi, who differed from them, as one of the lights of the reigning school, his name is now tacitly dropped in the writings of the members of that school. Whatever may have been his partial usefulness in vindicating the policy of free trade, it is at least plain that for the needs of our social future he has nothing to offer.
- Senior. Nassau William Senior (1790-1864), who was professor of political economy in the university of Oxford, published, besides a number of separate lectures, a treatise on the science, which first appeared as an article in the *Encyclopædia Metropolitana*. He is a writer of a high order of merit. He made considerable contributions to the elucidation of economic principles, specially studying exactness in nomenclature and strict accuracy in deduction. His explanations on cost of production and the way in which it affects price, on rent, on the difference between rate of wages and price of labour, on the relation between profit and wages (with special reference to Ricardo's theorem on this subject, which he corrects by the substitution of proportional for absolute amount), and on the distribution of the precious metals between different countries are particularly valuable. His new term "abstinence," invented to express the conduct for which interest is the remuneration, was useful, though not quite appropriate, because negative in meaning. It is on the question of wages that Senior is least satisfactory. He makes the average rate in a country (which, we must maintain, is not a real quantity, though the rate in a given employment and neighbourhood is) to be expressed by the fraction of which the numerator is the amount of the wages fund (an unascertainable and indeed, except as actual total of wages paid, imaginary sum) and the denominator the number of the working population; and from this he proceeds to draw the most important and far-reaching consequences, though the equation on which he founds his inferences conveys at most only an arithmetical fact, which would be true of every case of a division amongst individuals, and contains no economic element whatever. The phrase "wages fund" originated in some expressions of Adam Smith used only for the purpose of illustration, and never intended to be rigorously interpreted; and we shall see that the doctrine has been repudiated by several members of what is regarded as the orthodox school of political economy. As regards method, Senior makes the science a purely deductive one, in which there is no room for any other "facts" than the four fundamental propositions from which he undertakes to deduce all economic truth. And he does not regard himself as arriving at hypothetical conclusions; his postulates and his inferences are alike conceived as corresponding to actual phenomena.
- Torrens. Colonel Robert Torrens (1780-1864) was a prolific writer, partly on economic theory, but principally on its applications to financial and commercial policy. Almost the whole of the programme which was carried out in legislation by Sir Robert Peel had been laid down in principle in the writings of Torrens. He gave substantially the same theory of foreign trade which was afterwards stated by J. S. Mill in one of his *Essays on Unsettled Questions*. He was an early and earnest advocate of the repeal of the corn laws, but was not in favour of a general system of absolute free trade, maintaining that it is expedient to impose retaliatory duties to counteract similar duties imposed by foreign countries, and that a lowering of import duties on the productions of countries retaining their hostile tariffs would occasion an abstraction of the precious metals, and a decline in prices, profits, and wages. His principal writings of a general character were—*The Economist* [i.e., Physiocrat] refuted, 1808; *Essay on the Production of Wealth*, 1821; *Essay on the External Corn-trade* (eulogized by Ricardo), 1827; *The Budget, a Series of Letters on Financial, Commercial, and Colonial Policy*, 1841-3. Harriet Martineau (1802-1876) popularized the doctrines of Malthus and Ricardo in her *Illustrations of Political Economy* (1832-34), a series of tales, in which there is much excellent description, but the effect of the narrative is often marred by the somewhat ponderous disquisitions here and there thrown in, usually in the form of dialogue.

Other writers who ought to be named in any history of the science are Charles Babbage, *On the Economy of Machines and Manufactures* (1832), chiefly descriptive, but also in part theoretic; William Thomas Thornton, *Overpopulation and its Remedy* (1846), *A Plea for Peasant Proprietors* (1848), *On Labour* (1869; 2d ed., 1870); Herman Merivale, *Lectures on Colonization and Colonies*, (1841-2; new ed., 1861); T. C. Panfield, *The Organization of Industry explained* (1844; 2d ed., 1848); and Edward Gibbon Wakefield, *A View of the Art of Colonization*, 1849. Thomas Chalmers, well known in other fields of thought, was author of *The Christian and Civic Economy of Large Towns* (1821-36), and *On Political Economy in Connection with the Moral State and Moral Prospects of Society* (1832); he strongly opposed any system of legal charity, and, whilst justly insisting on the primary importance of morality, industry, and thrift as conditions of popular wellbeing, carried the Malthusian doctrines to excess. Nor was Ireland without a share in the economic movement of the period. Whately, having been second Drummond professor of political economy at Oxford (in succession to Senior), founded (1832), when he went to Ireland as archbishop of Dublin, a similar professorship in Trinity College, Dublin. It was first held by Mountfort Longfield, afterwards judge of the Landed Estates Court, Ireland (d. 1884). He published lectures on the science generally (1834), on *Poor Laws* (1834), and on *Commerce and Absenteeism* (1835), which were marked by independence of thought and sagacious observation. He was laudably free from many of the exaggerations of his contemporaries; he said, in 1835, "in political economy we must not abstract too much," and protested against the assumption too often made that "men are guided in all their conduct by a prudent regard to their own interest." James A. Lawson (now Mr Justice Lawson) also published some lectures (1844) delivered from the same chair, which may still be read with interest and profit; his discussion of the question of population is especially good; he also asserted against Senior that the science is *aride de faits*, and that it must reason about the world and mankind as they really are.

The most systematic and thorough-going contemporary Richard critic of the Ricardian system was Richard Jones (1790-Jones. 1855), professor at Haileybury. Jones has received scant justice at the hands of his successors. J. S. Mill, whilst using his work, gave his merits but faint recognition. Even Roscher says that he did not thoroughly understand Ricardo, without giving any proof of that assertion, whilst he is silent as to the fact that much of what has been preached by the German historical school is found distinctly indicated in Jones's writings. He has been sometimes represented as having rejected the Andersonian doctrine of rent; but such a statement is incorrect. Attributing the doctrine to Malthus, he says that that economist "showed satisfactorily that, when land is cultivated by capitalists living on the profits of their stock, and able to move it at pleasure to other employments, the expense of tilling the worst quality of land cultivated determines the average price of raw produce, while the difference of quality on the superior lands measures the rents yielded by them." What he really denied was the application of the doctrine to all cases where rent is paid; he pointed out in his *Essay on the Distribution of Wealth and on the Sources of Taxation*, 1831, that, besides "farmers' rents," which, under the supposed conditions, conform to the above law, there are "peasant rents," paid everywhere through the most extended periods of history, and still paid over by far the largest part of the earth's surface, which are not so regulated. Peasant rents he divided under the heads of (1) serf, (2) métayer, (3) ryot, and (4) cottier rents, a classification afterwards adopted in substance by J. S. Mill; and he showed that the contracts fixing their amount were, at least in the first three classes, determined rather by custom than by competition. Passing to the superstructure of theory erected by Ricardo on the doctrine of rent which he had so unduly extended, Jones denied most of the conclusions he had deduced, especially the following:—that the increase of farmers' rents is always contemporary with a decrease in the productive powers of agriculture, and comes with loss and distress in its train; that the interests of landlords are always and necessarily opposed to the interests of the state and of every other

class of society; that the diminution of the rate of profits is exclusively dependent on the returns to the capital last employed on the land; and that wages can rise only at the expense of profits.

The method followed by Jones is inductive; his conclusions are founded on a wide observation of contemporary facts, aided by the study of history. "If," he said, "we wish to make ourselves acquainted with the economy and arrangements by which the different nations of the earth produce and distribute their revenues, I really know but of one way to attain our object, and that is, to look and see. We must get comprehensive views of facts, that we may arrive at principles that are truly comprehensive. If we take a different method, if we snatch at general principles, and content ourselves with confined observations, two things will happen to us. First, what we call general principles will often be found to have no generality—we shall set out with declaring propositions to be universally true which, at every step of our further progress, we shall be obliged to confess are frequently false; and, secondly, we shall miss a great mass of useful knowledge which those who advance to principles by a comprehensive examination of facts necessarily meet with on their road." The world he professed to study was not an imaginary world, inhabited by abstract "economic men," but the real world with the different forms which the ownership and cultivation of land, and, in general, the conditions of production and distribution, assume at different times and places. His recognition of such different systems of life in communities occupying different stages in the progress of civilization led to his proposal of what he called a "political economy of nations." This was a protest against the practice of taking the exceptional state of facts which exists, and is indeed only partially realized, in a small corner of our planet as representing the uniform type of human societies, and ignoring the effects of the early history and special development of each community as influencing its economic phenomena.

It is sometimes attempted to elude the necessity for a wider range of study by alleging a universal tendency in the social world to assume this now exceptional shape as its normal and ultimate constitution. Even if this tendency were real (which is only partially true, for the existing order amongst ourselves cannot be regarded as entirely definitive), it could not be admitted that the facts witnessed in our civilization and those exhibited in less advanced communities are so approximate as to be capable of being represented by the same formulae. As Whewell, in editing Jones's *Remains*, 1859, well observed, it is true in the physical world that "all things tend to assume a form determined by the force of gravity; the hills tend to become plains, the waterfalls to eat away their beds and disappear, the rivers to form lakes in the valleys, the glaciers to pour down in cataracts." But are we to treat these results as achieved, because forces are in operation which may ultimately bring them about? As Comte has said, all human questions are largely questions of time; and the economic phenomena which really belong to the several stages of the human movement must be studied as they are, unless we are content to fall into grievous error both in our theoretic treatment of them and in the solution of the practical problems they present.

Jones is remarkable for his freedom from exaggeration and one-sided statement; thus, whilst holding Malthus in, perhaps, undue esteem, he declines to accept the proposition that an increase of the means of subsistence is necessarily followed by an increase of population; and he maintains what is undoubtedly true, that with the growth of population, in all well-governed and prosperous states, the command over food, instead of diminishing, increases.

Much of what he has left us—a large part of which is unfortunately fragmentary—is akin to the later labours of Cliffe Leslie. The latter, however, had the advantage of acquaintance with the sociology of Comte, which gave him a firmer grasp of method, as well as a wider view of the general movement of society; and, whilst the voice of Jones was but little heard amidst the general applause accorded to Ricardo in the economic world of his time, Leslie wrote when disillusion had set in, and the current was beginning to turn in England against the *a priori* economics.

Comte somewhere speaks of the "transient predilection" for political economy which had shown itself generally in western Europe. This phase of feeling was specially noticeable in England from the third to the fifth decade of the present century. "Up to the year 1818," said a writer in the *Westminster Review*, "the science was scarcely known or talked of beyond a small circle of philosophers; and legislation, so far from being in conformity with its principles, was daily receding from them more and more." Mill has told us what a change took place within a few years. "Political economy," he says, "had asserted itself with great vigour in public affairs by the

petition of the merchants of London for free trade, drawn up in 1820 by Mr Tooke and presented by Mr Alexander Baring, and by the noble exertions of Ricardo during the few years of his parliamentary life. His writings, following up the impulse given by the bullion controversy, and followed up in their turn by the expositions and comments of my father and McCulloch (whose writings in the *Edinburgh Review* during those years were most valuable), had drawn general attention to the subject, making at least partial converts in the cabinet itself; and Huskisson, supported by Canning, had commenced that gradual demolition of the protective system which one of their colleagues virtually completed in 1846, though the last vestiges were only swept away by Mr Gladstone in 1860." Whilst the science was thus attracting and fixing the attention of active minds, its unsettled condition was freely admitted. The differences of opinion among its professors were a frequent subject of complaint. But it was confidently expected that these discrepancies would soon disappear, and Colonel Torrens predicted that in twenty years there would scarcely "exist a doubt respecting any of its more fundamental principles." "The prosperity," says Mr Sidgwick, "that followed on the abolition of the corn laws gave practical men a most impressive and satisfying proof of the soundness of the abstract reasoning by which the expediency of free trade had been inferred," and when, in 1848, "a masterly expositor of J. S. thought had published a skilful statement of the chief results of the controversies of the preceding generation," with the due "explanations and qualifications" of the reigning doctrines, it was for some years generally believed that political economy had "emerged from the state of polemical discussion," at least on its leading doctrines, and that at length a sound construction had been erected on permanent bases.

This expositor was John Stuart Mill (1806-73). He exercised, without doubt, a greater influence in the field of English economics than any other writer since Ricardo. His systematic treatise has been, either directly or through manuals founded on it, especially that of Fawcett, the source from which most of our contemporaries in these countries have derived their knowledge of the science. But there are other and deeper reasons, as we shall see, which make him, in this as in other departments of knowledge, a specially interesting and significant figure.

In 1844 he published five *Essays on some Unsettled Questions of Political Economy*, which had been written as early as 1829 and 1830, but had, with the exception of the fifth, remained in manuscript. In these essays is contained any dogmatic contribution which he can be regarded as having made to the science. The subject of the first is the laws of interchange between nations. He shows that, when two countries trade together in two commodities, the prices of the commodities exchanged on both sides (which, as Ricardo had proved, are not determined by cost of production) will adjust themselves in such a way that the quantities required by each country of the article which it imports from its neighbour shall be exactly sufficient to pay for one another. This is the law which appears, with some added developments, in his systematic treatise under the name of the "equation of international demand." The most important practical conclusion (not, however, by any means an undisputed one) at which he arrives in this essay is, that the relaxation of duties on foreign commodities, not operating as protection but maintained solely for revenue, should be made contingent on the adoption of some corresponding degree of freedom of trade with England by the nation from which the commodities are imported. In the second essay, on the influence of con-

sumption on production, the most interesting results arrived at are the propositions—(1) that absenteeism is a local, not a national, evil, and (2) that, whilst there cannot be permanent excess of production, there may be a temporary excess, not only of any one article, but of commodities generally,—this last, however, not arising from over-production, but from a want of commercial confidence. The third essay relates to the use of the words "productive" and "unproductive" as applied to labour, to consumption, and to expenditure. The fourth deals with profits and interest, especially explaining and so justifying Ricardo's theorem that "profits depend on wages, rising as wages fall and falling as wages rise." What Ricardo meant was that profits depend on the cost of wages estimated in labour. Hence improvements in the production of articles habitually consumed by the labourer may increase profits without diminishing the real remuneration of the labourer. The last essay is on the definition and method of political economy, a subject afterwards more maturely treated in the author's *System of Logic*.

In 1848 Mill published his *Principles of Political Economy, with some of their Applications to Social Philosophy*. This title, though, as we shall see, open to criticism, indicated on the part of the author a less narrow and formal conception of the field of the science than had been common amongst his predecessors. He aimed, in fact, at producing a work which might replace in ordinary use the *Wealth of Nations*, which in his opinion was "in many parts obsolete and in all imperfect." Adam Smith had invariably associated the general principles of the subject with their applications, and in treating those applications had perpetually appealed to other and often far larger considerations than pure political economy affords. And in the same spirit Mill desired; whilst incorporating all the results arrived at in the special science by Smith's successors, to exhibit purely economic phenomena in relation to the most advanced conceptions of his own time in the general philosophy of society, as Smith had done in reference to the philosophy of his century.

This design he certainly failed to realize. His book is very far indeed from being a "modern Adam Smith." It is an admirably lucid and even elegant exposition of the Ricardian economics, the Malthusian theory being of course incorporated with these, but, notwithstanding the introduction of many minor novelties, it is, in its scientific substance, little or nothing more. When Cliffe Leslie says that Mill so qualified and amended the doctrines of Ricardo that the latter could scarcely have recognized them, he certainly goes a great deal too far; Senior really did more in that direction. Mill's effort is usually to vindicate his master where others have censured him, and to palliate his admitted laxities of expression. Already his profound esteem for Ricardo's services to economics had been manifest in his *Essays*, where he says of him, with some injustice to Smith, that, "having a science to create," he could not "occupy himself with more than the leading principles," and adds that "no one who has thoroughly entered into his discoveries" will find any difficulty in working out "even the minutiae of the science." James Mill, too, had been essentially an expounder of Ricardo; and the son, whilst greatly superior to his father in the attractiveness of his expository style, is, in regard to his economic doctrine, substantially at the same point of view. It is in their general philosophical conceptions and their views of social aims and ideals that the elder and younger Mill occupy quite different positions in the line of progress. The latter could not, for example, in his adult period have put forward as a theory of government the shallow sophistries which the plain good

sense of Macaulay sufficed to expose in the writings of the former; and he had a nobleness of feeling which, in relation to the higher social questions, raised him far above the ordinary coarse utilitarianism of the Benthamites.

The larger and more philosophic spirit in which Mill dealt with social subjects was undoubtedly in great measure due to the influence of Comte, to whom, as Mr Bain justly says, he was under greater obligations than he himself was disposed to admit. Had he more completely undergone that influence, we are sometimes tempted to think he might have wrought the reform in economics which still remains to be achieved, emancipating the science from the *a priori* system, and founding a genuine theory of industrial life on observation in the broadest sense. But probably the time was not ripe for such a construction, and it is possible that Mill's native intellectual defects might have made him unfit for the task, for, as Roscher has said, "ein historischer Kopf war er nicht." However this might have been, the effects of his early training, in which positive were largely alloyed with metaphysical elements, sufficed in fact to prevent his attaining a perfectly normal mental attitude. He never altogether overcame the vicious direction which he had received from the teaching of his father, and the influence of the Benthamite group in which he was brought up. Hence it was that, according to the striking expression of Roscher, his whole view of life was "zu wenig aus Einem Gusse." The incongruous mixture of the narrow dogmas of his youthful period with the larger ideas of a later stage gave a wavering and indeterminate character to his entire philosophy. He is, on every side, eminently "un-final"; he represents tendencies to new forms of opinion, and opens new vistas in various directions, but founds scarcely anything, and remains indeed, so far as his own position is concerned, not merely incomplete but incoherent. It is, however, precisely this dubious position which seems to us to give a special interest to his career, by fitting him in a peculiar degree to prepare and facilitate transitions.

What he himself thought to be "the chief merit of his treatise" was the marked distinction drawn between the theory of production and that of distribution, the laws of the former being based on unalterable natural facts, whilst the course of distribution is modified from time to time by the changing ordinances of society. This distinction, we may remark, must not be too absolutely stated, for the organization of production changes with social growth, and, as Lauderdale long ago showed, the nature of the distribution in a community reacts on production. But there is a substantial truth in the distinction, and the recognition of it tends to concentrate attention on the question—How can we improve the existing distribution of wealth? The study of this problem led Mill, as he advanced in years, further and further in the direction of socialism; and, whilst to the end of his life his book continued to deduce the Ricardian doctrines from the principle of enlightened selfishness, he was looking forward to an order of things in which synergy should be founded on sympathy.

The gradual modification of his views in relation to the economic constitution of society is set forth in his *Autobiography*. In his earlier days, he tells us, he "had seen little further than the *old school*" (note this significant title) "of political economy into the possibilities of fundamental improvement in social arrangements. Private property, as now understood, and inheritance appeared the *dernier mot* of legislation." The notion of proceeding to any radical redress of the injustice "involved in the fact that some are born to riches and the vast majority to poverty" he had then reckoned chimerical. But now his views were such as would "class him decidedly under the

general designation of socialist"; he had come to believe that the whole contemporary framework of economic life was merely temporary and provisional, and that a time would come when "the division of the produce of labour, instead of depending, as in so great a degree it now does, on the accident of birth, would be made by concert on an acknowledged principle of justice." "The social problem of the future" he considered to be "how to unite the greatest individual liberty of action," which was often compromised in socialistic schemes, "with a common ownership in the raw material of the globe, and an equal participation in all the benefits of combined labour." These ideas were scarcely indicated in the first edition of the *Political Economy*, rather more clearly and fully in the second, and quite unequivocally in the third,—the French Revolution of 1848 having, as he says, made the public more open to the reception of novelties in opinion.

Whilst thus looking forward to a new economic order, he yet thinks its advent very remote, and believes that the inducements of private interest will in the meantime be indispensable. On the spiritual side he maintains a similar attitude of expectancy. He anticipates the ultimate disappearance of theism, and the substitution of a purely human religion, but believes that the existing doctrine will long be necessary as a stimulus and a control. He thus saps existing foundations without providing anything to take their place, and maintains the necessity of conserving for indefinite periods what he has radically discredited. Nay, even whilst sowing the seeds of change in the direction of a socialistic organization of society, he favours present or proximate arrangements which would urge the industrial world towards other issues. The system of peasant proprietorship of land is distinctly individualistic in its whole tendency; yet he extravagantly praises it in the earlier part of his book, only receding from that laudation when he comes to the chapter on the future of the labouring classes. And the system of so-called cooperation in production which he so warmly commended in the later editions of his work, and led some of his followers to preach as the one thing needful, would inevitably strengthen the principle of personal property, and, whilst professing at most to substitute the competition of associations for that of individuals, would by no means exclude the latter.

The elevation of the working classes he bound up too exclusively with the Malthusian ethics, on which he laid quite an extravagant stress, though, as Mr Bain has observed, it is not easy to make out his exact views, any more than his father's, on this subject. We have no reason to think that he ever changed his opinion as to the necessity of a restriction on population; yet that element seems foreign to the socialistic idea to which he increasingly leaned. It is at least difficult to see how, apart from individual responsibility for the support of a family, what Malthus called moral restraint could be enforced. This difficulty is indeed the fatal flaw which, in Malthus's own opinion, vitiated the scheme of Godwin.

Mill's openness to new ideas and his enthusiasm for improvement cannot be too much admired. But there appears to have been combined with these fine traits in his mental constitution a certain want of practical sense, a failure to recognize and acquiesce in the necessary conditions of human life, and a craving for "better bread than can be made of wheat." He entertained strangely exaggerated, or rather perverted, notions of the "subjection," the capacities, and the rights of women. He encourages a spirit of revolt on the part of working men against their perpetual condemnation, as a class, to the lot of living by wages, without giving satisfactory proof that this state of things is capable of change, and without

showing that such a lot, duly regulated by law and morality, is inconsistent with their real happiness. He also insists on the "independence" of the working class—which according to him *farà da se*—in such a way as to obscure, if not to controvert, the truths that superior rank and wealth are naturally invested with social power, and are bound in duty to exercise it for the benefit of the community at large, and especially of its less favoured members. And he attaches a quite undue importance to mechanical and, indeed, illusory expedients, such as the limitation of the power of bequest and the confiscation of the "unearned increment" of rent.

With respect to economic method also, he shifted his position; yet to the end occupied uncertain ground. In the fifth of his early essays he asserted that the method *a priori* is the only mode of investigation in the social sciences, and that the method *a posteriori* "is altogether inefficacious in those sciences, as a means of arriving at any considerable body of valuable truth." When he wrote his *Logic*, he had learned from Comte that the *a posteriori* method—in the form which he chose to call "inverse deduction"—was the only mode of arriving at truth in general sociology; and his admission of this at once renders the essay obsolete. But, unwilling to relinquish the *a priori* method of his youth, he tries to establish a distinction of two sorts of economic inquiry, one of which, though not the other, can be handled by that method. Sometimes he speaks of political economy as a department "carved out of the general body of the science of society"; whilst on the other hand the title of his systematic work implies a doubt whether political economy is a part of "social philosophy" at all, and not rather a study preparatory and auxiliary to it. Thus, on the logical as well as the dogmatic side, he halts between two opinions. Notwithstanding his misgivings and even disclaimers, he yet remained, as to method, a member of the old school, and never passed into the new or "historical" school, to which the future belongs.

The question of economic method was also taken up by the ablest of his disciples, John Elliott Cairnes (1824–75), who devoted a volume to the subject (*Logical Method of Political Economy*, 1857; 2d ed., 1875). Prof. Walker has lately spoken of the method advocated by Cairnes as different from that put forward by Mill, and has even represented the former as similar to, if not identical with, that of the German historical school. But this is certainly an error. Cairnes, notwithstanding some apparent vacillation of view and certain concessions more formal than real, maintains the utmost rigour of the deductive method; he distinctly affirms that in political economy there is no room for induction at all, "the economist starting with a knowledge of ultimate causes," and being thus, "at the outset of his enterprise, at the position which the physicist only attains after ages of laborious research." He does not, indeed, seem to be advanced beyond the point of view of Senior, who professed to deduce all economic truth from four elementary propositions. Whilst Mill in his *Logic* represents verification as an essential part of the process of demonstration of economic laws, Cairnes holds that, as they "are not assertions respecting the character or sequence of phenomena" (though what else can a scientific law be?), "they can neither be established nor refuted by statistical or documentary evidence." A proposition which affirms nothing respecting phenomena cannot be controlled by being confronted with phenomena. Notwithstanding the unquestionable ability of his book, it appears to mark, in some respects, a retrogression in methodology, and can for the future possess only an historical interest.

Regarded in that light, the labours of Mill and

Cairnes on the method of the science, though intrinsically unsound, had an important negative effect. They let down the old political economy from its traditional position, and reduced its extravagant pretensions by two modifications of commonly accepted views. First, whilst Ricardo had never doubted that in all his reasonings he was dealing with human beings as they actually exist, they showed that the science must be regarded as a purely hypothetical one. Its deductions are based on unreal, or at least one-sided, assumptions, the most essential of which is that of the existence of the so-called "economic man," a being who is influenced by two motives only, that of acquiring wealth and that of avoiding exertion; and only so far as the premises framed on this conception correspond with fact can the conclusions be depended on in practice. Senior in vain protested against such a view of the science, which, as he saw, compromised its social efficacy; whilst Torrens, who had previously combated the doctrines of Ricardo, hailed Mill's new presentation of political economy as enabling him, whilst in one sense rejecting those doctrines, in another sense to accept them. Secondly, beside economic science, it had often been said, stands an economic art,—the former ascertaining truths respecting the laws of economic phenomena, the latter prescribing the right kind of economic action; and many had assumed that, the former being given, the latter is also in our possession—that, in fact, we have only to convert theorems into precepts, and the work is done. But Mill and Cairnes made it plain that this statement could not be accepted, that action can no more in the economic world than in any other province of life be regulated by considerations borrowed from that department of things only, that economics can suggest ideas which are to be kept in view, but that, standing alone, it cannot direct conduct—an office for which a wider prospect of human affairs is required. This matter is best elucidated by a reference to Comte's classification, or rather hierarchical arrangement, of the sciences. Beginning with the least complex, mathematics, we rise successively to astronomy, physics, chemistry, thence to biology, and from it again to sociology. In the course of this ascent we come upon all the great laws which regulate the phenomena of the inorganic world, of organized beings, and of society. A further step, however, remains to be taken—namely, to morals; and at this point theory and practice tend to coincide, because every element of conduct has to be considered in relation to the general good. In the final synthesis all the previous analyses have to be used as instrumental, in order to determine how every real quality of things or men may be made to converge to the welfare of humanity.

Cairnes's most important economic publication was his last, entitled *Some Leading Principles of Political Economy newly Expounded*, 1874. In this work, which does not profess to be a complete treatise on the science, he criticizes and emends the statements which preceding writers had given of some of its principal doctrines, and treats elaborately of the limitations with which they are to be understood, and the exceptions to them which may be produced by special circumstances. Whilst marked by great ability, it affords evidence of what has been justly observed as a weakness in Cairnes's mental constitution—his "deficiency in intellectual sympathy," and consequent frequent inability to see more than one side of a truth.

The three divisions of the book relate respectively to (1) value, (2) labour and capital, and (3) international trade. In the first he begins by elucidating the meaning of the word "value," and under this head controverts the view of Jevons that the exchange value of anything depends entirely on its utility, without, perhaps, distinctly apprehending what Jevons meant by this proposition. On supply and demand he shows, as Say had done before, that these, regarded as aggregates, are not independent, but strictly connected

and mutually dependent phenomena—identical, indeed, under a system of barter, but, under a money system, conceivable as distinct. Supply and demand with respect to particular commodities must be understood to mean supply and demand at a given price; and thus we are introduced to the ideas of market price and normal price (as, following Cherbuliez, he terms what Smith less happily called natural price). Normal price again leads to the consideration of cost of production, and here, against Mill and others, he denies that profit and wages enter into cost of production; in other words, he asserts what Senior (whom he does not name) had said before him, though he had not consistently carried out the nomenclature, that cost of production is the sum of labour and abstinence necessary to production, wages and profits being the remuneration of sacrifice and not elements of it. But, it may well be asked, how can an amount of labour be added to an amount of abstinence? Must not wages and profits be taken as "measures of cost?" By adhering to the conception of "sacrifice," he exposes the emptiness of the assertion that "dear labour is the great obstacle to the extension of British trade"—a sentence in which "British trade" means capitalists' profits. At this point we are introduced to a doctrine now first elaborated, though there are indications of it in Mill, of whose theory of international values it is in fact an extension. In foreign trade cost of production, in Cairnes's sense, does not regulate values, because it cannot perform that function except under a régime of effective competition, and between different countries effective competition does not exist. But, Cairnes asks, to what extent does it exist in domestic industries? So far as capital is concerned, he thinks the condition is sufficiently fulfilled over the whole field—a position, let it be said in passing, which he does not seem to make out, if we consider the practical immobility of most invested, as distinct from disposable, capital. But in the case of labour the requisite competition takes place only within certain social, or rather industrial, strata. The world of industry may be divided into a series of superposed groups, and these groups are practically "non-competing," the disposable labour in any one of them being rarely capable of choosing its field in a higher. The law that cost of production determines price cannot, therefore, be absolutely stated respecting domestic any more than respecting international exchange: as it fails for the latter universally, so it fails for the former as between non-competing groups. The law that holds between these is similar to that governing international values, which may be called the equation of reciprocal demand. Such a state of relative prices will establish itself amongst the products of these groups as shall enable that portion of the products of each group which is applied to the purchase of the products of all other groups to discharge its liabilities towards those other groups. The reciprocal demand of the groups determines the "average relative level" of prices within each group; whilst cost of production regulates the distribution of price among the individual products of each group. This theorem is perhaps of no great practical value; but the tendency of the whole investigation is to attenuate the importance of cost of production as a regulator of normal price, and so to show that yet another of the accepted doctrines of the science had been propounded in too rigid and absolute a form. As to market price, the formula by which Mill had defined it as the price which equalizes demand and supply Cairnes shows to be an identical proposition, and he defines it as the price which most advantageously adjusts the existing supply to the existing demand pending the coming forward of fresh supplies from the sources of production.

His second part is chiefly remarkable for his defence of what is known as the wages fund doctrine, to which we adverted when speaking of Senior. Mill had given up this doctrine, having been convinced by Thornton that it was erroneous; but Cairnes refused to follow his leader, who, as he believes, ought not to have been convinced. After having given what is certainly a fallacious reply to Longe's criticism of the expression "average rate of wages," he proceeds to vindicate the doctrine in question by the consideration that the amount of a nation's wealth devoted at any time to the payment of wages—if the character of the national industries and the methods of production employed remain the same—is in a definite relation to the amount of its general capital; the latter being given, the former is also given. In illustrating his view of the subject, he insists on the principle (true in the main, but too absolutely formulated by Mill) that "demand for commodities is not demand for labour." It is not necessary here to follow his investigation, for his reasoning has not satisfied his successors, with the exception of Fawcett, and the question of wages is now commonly treated without reference to a supposed determinate wages fund. Cairnes next studies trades-unionism in relation to wages, and arrives in substance at the conclusion that the only way in which it can affect their rate is by accelerating an advance which must ultimately have taken place independently of its action. He also takes occasion to refute Mr (now Sir Thomas) Brassey's supposed law of a uniform cost of labour in every part of the world. Turning to consider the material prospects of the working classes, he examines

the question of the changes which may be expected in the amount and partition of the fund out of which abstinence and labour are remunerated. He here enunciates the principle (which had been, however, stated before him by Ricardo and Senior) that the increased productiveness of industry will not affect either profit or wages, unless it cheapen the commodities which the labourer consumes. These latter being mostly commodities of which raw produce is the only or principal element, their cost of production, notwithstanding improvements in knowledge and art, will increase unless the numbers of the labouring class be steadily kept in check; and hence the possibility of elevating the condition of the labourer is confined within very narrow limits, if he continues to be a labourer only. The condition of any substantial and permanent improvement in his lot is that he should cease to be a mere labourer—that profits should be brought to reinforce the wages fund, which has a tendency to decline relatively to the general capital of a country. And hence Cairnes—abandoning the purely theoretic attitude which he elsewhere represents as the only proper one for the economist—recommends the system of so-called co-operation (that is, in fact, the abolition of the large capitalist) as offering to the working classes “the sole means of escape from a harsh and hopeless destiny,” and puts aside rather contemptuously the opposition of the positivists to this solution, which yet many besides the positivists, as, for example, Leslie and F. A. Walker, regard as chimerical.

The third part is devoted mainly to an exposition of Ricardo's doctrine of the conditions of international trade and Mill's theory of international values. The former Cairnes modifies by introducing his idea of the partial influence of reciprocal demand, as distinguished from cost of production, on the regulation of domestic prices, and founds on this rectification an interesting account of the connexion between the wages prevailing in a country and the character and course of its external trade. He amends Mill's statement, which represented the produce of a country as exchanging for that of other countries at such values “as are required in order that the whole of her exports may exactly pay for the whole of her imports” by substituting for the latter phrase the condition that each country should by means of her exports discharge all her foreign liabilities—in other words, by introducing the consideration of the balance of debts. This idea was not new; it had been indicated by J. L. Foster as early as 1804, and was touched on by Mill himself; but he expounds it well; and it is important as clearing away common misconceptions, and sometimes removing groundless alarms. Passing to the question of free trade, he disposes of some often-repeated protectionist arguments, and in particular refutes the American allegation of the inability of the highly-paid labour of that country to compete with the “pauper labour” of Europe. He is not so successful in meeting the “political argument,” founded on the admitted importance for civilization of developing diversified national industries; and he meets only by one of the highly questionable commonplaces of the doctrinaire economists Mill's proposition that protection may foster nascent industries really adapted to a country till they have struck root and are able to endure the stress of foreign competition.

We have dwelt at some length on this work of Cairnes, not only because it presents the latest forms of several accepted economic doctrines, but also because it is, and, we believe, will remain, the last important product of the old English school. The author at the outset expresses the hope that it will strengthen, and add consistence to, the scientific fabric “built up by the labours of Adam Smith, Malthus, Ricardo, and Mill.” Whilst recognizing with him the great merits of Smith, and the real abilities and services of his three successors here named, we cannot entertain the same opinion as Cairnes respecting the permanence of the fabric they constructed. We hold that a new edifice is required, incorporating indeed many of the materials of the old, but planned on different ideas and in some respects with a view to different ends—above all, resting on different philosophic foundations, and having relation in its whole design to the more comprehensive structure of which it will form but one department, namely, the general science of society.

We have already had occasion to refer to Cairnes's *Essays in Political Economy*, 1873. His *Slave Power* (1862) was the most valuable work which appeared on the subject of the great American conflict.

*France.*—All the later European schools presuppose—in part adopting, in part criticizing—the work of the English economists from Smith<sup>1</sup> to Ricardo and the Epigoni. The

<sup>1</sup> The first French translation of the *Wealth of Nations*, by Blavet, appeared in the *Journal de l'Agriculture, du Commerce, des Finances, et des Arts*, 1779–80; new editions of it were published in 1781, 1788, and 1800; it was also printed at Amsterdam in 1784. Smith himself recommended it in his third edition of the original as excellent. In 1790 appeared the translation by Roscher, with notes by Condorcet, and in 1802 that by Count Germain Garnier, executed during his exile in England, which is now considered the standard version, and has been reproduced, with notes by Say, Sismondi, Blavet, &c., in the *Collection des Principaux Économistes*.

German school has had in a greater degree than any other a movement of its own,—following, at least in its more recent period, an original method, and tending to special and characteristic conclusions. The French school, on the other hand,—if we omit the socialists, who do not here come under consideration,—has in the main reproduced the doctrines of the leading English thinkers,—stopping short, however, in general of the extremes of Ricardo and his disciples. In the field of exposition the French are unrivalled; and in political economy they have produced a series of more or less remarkable systematic treatises, text books, and compendiums, at the head of which stands the celebrated work of J. B. Say. But the number of seminal minds which have appeared in French economic literature—of writers who have contributed important truths, introduced improvements of method, or presented the phenomena under new lights—has not been large. Sismondi, Dunoyer, and Bastiat will deserve our attention, as being the most important of those who occupy independent positions (whether permanently tenable or not), if we pass over for the present the great philosophical renovation of Auguste Comte, which comprehended actually or potentially all the branches of sociological inquiry. Before estimating the labours of Bastiat, we shall find it desirable to examine the views of Carey, the most renowned of American economists, with which the latest teachings of the ingenious and eloquent Frenchman are, up to a certain point, in remarkable agreement. Cournot, too, must find a place among the French writers of this period, as the chief representative of the conception of a mathematical method in political economy.

Of Jean Baptiste Say (1767–1832) Ricardo says—“He Say was the first, or among the first, of Continental writers who justly appreciated and applied the principles of Smith, and has done more than all other Continental writers taken together to recommend that enlightened and beneficial system to the nations of Europe.” The *Wealth of Nations* in the original language was placed in Say's hands by Clavière, afterwards minister, then director of the assurance society of which Say was a clerk; and the book made a powerful impression on him. Long after, when Dupont de Nemours complained of his injustice to the physiocrats, and claimed him as, through Smith, a spiritual grandson of Quesnay and nephew of Turgot, he replied that he had learned to read in the writings of the mercantile school, had learned to think in those of Quesnay and his followers, but that it was in Smith that he had learned to seek the causes and the effects of social phenomena in the nature of things, and to arrive at this last by a scrupulous analysis. His *Traité d'Économie Politique* (1803) was essentially founded on Smith's work, but he aimed at arranging the materials in a more logical and instructive order. He has the French art of easy and lucid exposition, though his facility sometimes degenerates into superficiality; and hence his book became popular, both directly and through translations obtained a wide circulation, and diffused rapidly through the civilized world the doctrines of the master. Say's knowledge of common life, says Roscher, was equal to Smith's; but he falls far below him in living insight into larger political phenomena, and he carefully eschews historical and philosophical explanations. He is sometimes strangely shallow, as when he says that “the best tax is that smallest in amount.” He appears not to have much claim to the position of an original thinker in political economy. Ricardo, indeed, speaks of him as having “enriched the science by several discussions, original, accurate, and profound.” What he had specially in view in using these words was what is, perhaps rather pretentiously, called Say's *théorie des débouchés*, with his connected disproof of the possibility of a universal glut.

The theory amounts simply to this, that buying is also selling, and that it is by producing that we are enabled to purchase the products of others. Several distinguished economists, especially Malthus and Sismondi, in consequence chiefly of a misinterpretation of the phenomena of commercial crises, maintained that there might be general over-supply or excess of all commodities above the demand. This Say rightly denied. A particular branch of production may, it must indeed be admitted, exceed the existing capabilities of the market; but, if we remember that supply is demand, that commodities are purchasing power, we cannot accept the doctrine of the possibility of a universal glut without holding that we can have too much of everything—that “all men can be so fully provided with the precise articles they desire as to afford no market for each other’s superfluities.” But, whatever services he may have rendered by original ideas on those or other subjects, his great merit is certainly that of a propagandist and popularizer.

The imperial police would not permit a second edition of his work to be issued without the introduction of changes which, with noble independence, he refused to make; and that edition did not therefore appear till 1814. Three other editions were published during the life of the author—in 1817, 1819, and 1826. In 1828 Say published a second treatise, *Cours complet d’Économie Politique Pratique*, which contained the substance of his lectures at the Conservatoire des Arts et Métiers and at the Collège de France. Whilst in his earlier treatise he had kept within the narrow limits of strict economics, in his later work he enlarged the sphere of discussion, introducing in particular many considerations respecting the economic influence of social institutions.

Ismaill. Jean Charles L. Simonde de Sismondi (1773-1842), author of the *Histoire des Républiques Italiennes du moyen âge*, represents in the economic field a protest, founded mainly on humanitarian sentiment, against the dominant doctrines. He wrote first a treatise *De la Richesse Commerciale* (1803), in which he followed strictly the principles of Adam Smith. But he afterwards came to regard these principles as insufficient and requiring modification. He contributed an article on political economy to the *Edinburgh Encyclopedia*, in which his new views were partially indicated. They were fully developed in his principal economic work, *Nouveaux Principes d’Économie Politique, ou de la Richesse dans ses rapports avec la Population* (1819; 2d ed., 1827). This work, as he tells us, was not received with favour by economists, a fact which he explains by the consideration that he had “attacked an orthodoxy—an enterprise dangerous in philosophy as in religion.” According to his view, the science, as commonly understood, was too much of a mere chrematistic: it studied too exclusively the means of increasing wealth, and not sufficiently the use of this wealth for producing general happiness. The practical system founded on it tended, as he believed, not only to make the rich richer, but to make the poor poorer and more dependent; and he desired to fix attention on the question of distribution as by far the most important, especially in the social circumstances of recent times.

The personal union in Sismondi of three nationalities, the Italian, the French, and the Swiss, and his comprehensive historical studies, gave him a special largeness of view; and he was filled with a noble sympathy for the suffering members of society. He stands nearer to socialism than any other French economist proper, but it is only in sentiment, not in opinion, that he approximates to it; he does not recommend any socialistic scheme. On the contrary, he declares in a memorable passage that, whilst he sees where justice lies, he must confess himself

unable to suggest the means of realizing it in practice; the division of the fruits of industry between those who are united in their production appears to him vicious; but it is, in his judgment, almost beyond human power to conceive any system of property absolutely different from that which is known to us by experience. He goes no further than protesting, in view of the great evils which he saw around him, against the doctrine of *laissez faire*, and invoking, somewhat vaguely, the intervention of Governments to “regulate the progress of wealth” and to protect the weaker members of the community.

His frank confession of impotence, far wiser and more honourable than the suggestion of precipitate and dangerous remedies, or of a recurrence to outworn mediæval institutions, has not affected the reputation of the work. A prejudice was indeed early created against it in consequence of its partial harmony of tone, though, as we have seen, not of policy, with socialism, which was then beginning to show its strength, as well as by the rude way in which his descriptions of the modern industrial system, especially as it existed in England, disturbed the complacent optimism of some members of the so-called orthodox school. These treated the book with ill-disguised contempt, and Bastiat spoke of it as preaching an *économie politique à rebours*. But it has held its place in the literature of the science, and is now even more interesting than when it first appeared, because in our time there is a more general disposition, instead of denying or glossing over the serious evils of industrial society, to face and remove or at least mitigate them. The *laissez faire* doctrine, too, has been discredited in theory and abandoned in practice; and we are ready to admit Sismondi’s view of the state as a power not merely intrusted with the maintenance of peace, but charged also with the mission of extending the benefits of the social union and of modern progress as widely as possible through all classes of the community. Yet the impression which his treatise leaves behind it is a discouraging one; and this because he regards as essentially evil many things which seem to be the necessary results of the development of industry. The growth of a wealthy capitalist class and of manufacture on the great scale, the rise of a vast body of workers who live by their labour alone, the extended application of machines, large landed properties cultivated with the aid of the most advanced appliances—all these he dislikes and deprecates; but they appear to be inevitable. The problem is, how to regulate and moralize the system they imply; but we must surely accept it in principle, unless we aim at a thorough social revolution. Sismondi may be regarded as the precursor of the German economists known under the inexact designation of “Socialists of the Chair”; but their writings are much more hopeful and inspiring.

To the subject of population he devotes special care, as of great importance for the welfare of the working classes. So far as agriculturists are concerned, he thinks the system of what he calls patriarchal exploitation, where the cultivator is also proprietor, and is aided by his family in tilling the land—a law of equal division among the natural heirs being apparently presupposed—the one which is most efficacious in preventing an undue increase of the population. The father is, in such a case, able distinctly to estimate the resources available for his children, and to determine the stage of subdivision which would necessitate the descent of the family from the material and social position it had previously occupied. When children beyond this limit are born, they do not marry, or they choose amongst their number one to continue the race. This is the view which, adopted by J. S. Mill, makes so great a figure in the too favourable presentation by that writer of the system of peasant proprietors.

In no French economic writer is greater force or general Dunoyer. solidity of thought to be found than in Charles Dunoyer (1786-1862), author of *La Liberté du Travail* (1845; the substance of the first volume had appeared under a different title in 1825), honourably known for his integrity and independence under the régime of the Restoration. What makes him of special importance in the history of the science is his view of its philosophical constitution and method. With respect to method, he strikes the keynote at the very outset in the words “rechercher expérimentalement,” and in professing to build on “les données de l’observation et de l’expérience.” He shows a marked tendency to widen economics into a general science of society, expressly describing political economy as having for its province the whole order of things which results from the exercise and development of the social forces.

This larger study is indeed better named sociology; and economic studies are better regarded as forming one department of it. But the essential circumstance is that, in Dunoyer's treatment of his great subject, the widest intellectual, moral, and political considerations are inseparably combined with purely economic ideas. It must not be supposed that by liberty, in the title of his work, is meant merely freedom from legal restraint or administrative interference; he uses it to express all that tends to give increased efficiency to labour. He is thus led to discuss all the causes of human progress, and to exhibit them in their historical working.

Treating, in the first part, of the influence of external conditions, of race, and of culture on liberty in this wider sense, he proceeds to divide all productive effort into two great classes, according as the action is exercised on things or on men, and censures the economists for having restricted their attention to the former. He studies in his second and third parts respectively the conditions of the efficiency of these two forms of human exertion. In treating of economic life, strictly so called, he introduces his fourfold division of material industry, in part adopted by J. S. Mill, as "(1) extractive, (2) *voiturière*, (3) *manufacturière*, (4) *agricole*," a division which is useful for physical economics, but will always, when the larger social aspect of things is considered, be inferior to the more commonly accepted one into agricultural, manufacturing, and commercial industry, banking being supposed as common president and regulator. Dunoyer, having in view only action on material objects, relegates banking, as well as commerce proper, to the separate head of exchange, which, along with association and gratuitous transmission (whether *inter vivos* or *mortis causa*), he classes apart as being, not industries, in the same sense with the occupations named, but yet functions essential to the social economy. The industries which act on man he divides according as they occupy themselves with (1) the amelioration of our physical nature, (2) the culture of our imagination and sentiments, (3) the education of our intelligence, and (4) the improvement of our moral habits; and he proceeds accordingly to study the social offices of the physician, the artist, the educator, and the priest. We meet in Dunoyer the ideas afterwards emphasized by Bastiat that the real subjects of human exchange are services; that all value is due to human activity; that the powers of nature always render a gratuitous assistance to the labour of man; and that the rent of land is really a form of interest on invested capital. Though he had disclaimed the task of a practical adviser in the often-quoted sentence—"Je n'impose rien; je ne propose même rien; j'expose," he finds himself, like all economists, unable to abstain from offering counsel. And his policy is opposed to any state interference with industry. Indeed he preaches in its extreme rigour the *laissez faire* doctrine, which he maintains principally on the ground that the spontaneous efforts of the individual for the improvement of his condition, by developing foresight, energy, and perseverance, are the most efficient means of social culture. But he certainly goes too far when he represents the action of Governments as normally always repressive and never directive. He was doubtless led into this exaggeration by his opposition to the artificial organizations of labour proposed by so many of his contemporaries, against which he had to vindicate the principle of competition; but his criticism of these schemes took, as Comte remarks, too absolute a character, tending to the perpetual interdiction of a true systematization of industry.

Digression on American economists. Franklin. At this point it will be convenient to turn aside and notice the doctrines of the American economist Carey. Not much had been done before him in the science by citizens of the United States. Benjamin Franklin, otherwise of world-wide renown, was author of a number of tracts, in most of which he merely enforces practical lessons of industry and thrift, but in some throws out interesting theoretic ideas. Thus, fifty years before Smith, he suggested (as Petty, however, had already done) human labour as the true measure of value (*Modest Inquiry into the Nature and Necessity of a Paper Currency*, 1721), and in his *Observations concerning the Increase of Mankind* (1751) he expresses views akin to those of Malthus. Alexander Hamilton, secretary of the treasury, in 1791 presented in his official capacity to the House of Representatives of the United States a report on the measures by which home manufactures could be promoted. In this document he gives a critical account of the theory of the subject, represents Smith's system of free trade as possible

in practice only if adopted by all nations simultaneously, ascribes to manufactures a greater productiveness than to agriculture, and seeks to refute the objections against the development of the former in America founded on the want of capital, the high rate of wages, and the low price of land. The conclusion at which he arrives is that for the creation of American manufactures a system of moderate protective duties was necessary, and he proceeds to describe the particular features of such a system. There is some reason to believe that the German economist List, of whom we shall speak hereafter, was influenced by Hamilton's work, having, during his exile from his native country, resided in Pennsylvania, and may have come into communication with Hamilton, who lived in a neighbouring State.

Henry Charles Carey (1793-1879), son of an American Carey, citizen who had emigrated from Ireland, represents a reaction against the dispiriting character which the Smithian doctrines had assumed in the hands of Malthus and Ricardo. His aim was, whilst adhering to the individualistic economy, to place it on a higher and surer basis, and fortify it against the assaults of socialism, to which some of the Ricardian tenets had exposed it. The most comprehensive as well as mature exposition of his views is contained in his *Principles of Social Science* (1859). Inspired with the optimistic sentiment natural to a young and rising nation with abundant undeveloped resources and an unbounded outlook towards the future, he seeks to show that there exists, independently of human wills, a natural system of economic laws, which is essentially beneficent, and of which the increasing prosperity of the whole community, and especially of the working classes, is the spontaneous result,—capable of being defeated only by the ignorance or perversity of man resisting or impeding its action. He rejects the Malthusian doctrine of population, maintaining that numbers regulate themselves sufficiently in every well governed society, and that their pressure on subsistence characterizes the lower, not the more advanced, stages of civilization. He rightly denies the universal truth, for all stages of cultivation, of the law of diminishing returns from land. His fundamental theoretic position relates to the antithesis of wealth and value.

Wealth had been by most economists confounded with the sum of exchange values; even Smith, though at first distinguishing them, afterwards allowed himself to fall into this error. Ricardo had, indeed, pointed out the difference, but only near the end of his treatise, in the body of which value alone is considered. The later English economists had tended to regard their studies as conversant only with exchange; so far had this proceeded that Whately had proposed for the science the name of *Catalactics*. When wealth is considered as what it really is, the sum of useful products, we see that it has its origin in external nature as supplying both materials and physical forces, and in human labour as appropriating and adapting those natural materials and forces. Nature gives her assistance gratuitously; labour is the sole foundation of value. The less we can appropriate and employ natural forces in any production the higher the value of the product, but the less the addition to our wealth in proportion to the labour expended. Wealth, in its true sense of the sum of useful things, is the measure of the power we have acquired over nature, whilst the value of an object expresses the resistance of nature which labour has to overcome in order to produce the object. Wealth steadily increases in the course of social progress; the exchange value of objects, on the other hand, decreases. Human intellect and faculty of social combination secure increased command over natural powers, and use them more largely in production, whilst less labour is spent in achieving each result, and the value of the product accordingly falls. The value of the article is not fixed by its cost of production in the past; what really determines it is the cost which is necessary for its reproduction under the present conditions of knowledge and skill. The dependence of value on cost, so interpreted, Carey holds to be universally true; whilst Ricardo maintained it only with respect to objects capable of indefinite multiplication, and in particular did not regard it as applicable to the case of land. Ricardo saw in the productive powers of land a free gift of nature which had been monopolized by a certain number

of persons, and which became, with the increased demand for food, a larger and larger value in the hands of its possessors. To this value, however, as not being the result of labour, the owner had no rightful claim; he could not justly demand a payment for what was done by the "original and indestructible powers of the soil." But Carey held that land, as we are concerned with it in industrial life, is really an instrument of production which has been formed as such by man, and that its value is due to the labour expended on it in the past,—though measured, not by the sum of that labour, but by the labour necessary under existing conditions to bring new land to the same stage of productiveness. He studies the occupation and reclamation of land with peculiar advantage as an American, for whom the traditions of first settlement are living and fresh, and before whose eyes the process is indeed still going on. The difficulties of adapting a primitive soil to the work of yielding organic products for man's use can be lightly estimated only by an inhabitant of a country long under cultivation. It is, in Carey's view, the overcoming of these difficulties by arduous and continued effort that entitles the first occupier of land to his property in the soil. Its present value forms a very small proportion of the cost expended on it, because it represents only what would be required, with the science and appliances of our time, to bring the land from its primitive into its present state. Property in land is therefore only a form of invested capital—a quantity of labour or the fruits of labour permanently incorporated with the soil; for which, like any other capitalist, the owner is compensated by a share of the produce. He is not rewarded for what is done by the powers of nature, and society is in no sense defrauded by his sole possession. The so-called Ricardian theory of rent is a speculative fancy, contradicted by all experience. Cultivation does not in fact, as that theory supposes, begin with the best, and move downwards to the poorer soils in the order of their inferiority.<sup>1</sup> The light and dry higher lands are first cultivated; and only when population has become dense and capital has accumulated, are the low-lying lands, with their greater fertility, but also with their miasmata, inundations, and miasmas, attacked and brought into occupation. Rent, regarded as a proportion of the produce, sinks, like all interest on capital, in process of time, but, as an absolute amount, increases. The share of the labourer increases, both as a proportion and an absolute amount. And thus the interests of these different social classes are in harmony.

But, Carey proceeds to say, in order that this harmonious progress may be realized, what is taken from the land must be given back to it. All the articles derived from it are really separated parts of it, which must be restored on pain of its exhaustion. Hence the producer and the consumer must be close to each other; the products must not be exported to a foreign country in exchange for its manufactures, and thus go to enrich as manure a foreign soil. In immediate exchange value the landowner may gain by such exportation, but the productive powers of the land will suffer. And thus Carey, who had set out as an earnest advocate of free trade, arrives at the doctrine of protection: the "co-ordinating power" in society must intervene to prevent private advantage from working public mischief.<sup>2</sup> He attributes his conversion on this question to his observation of the effects of liberal and protective tariffs respectively on American prosperity. This observation, he says, threw him back on theory, and led him to see that the intervention referred to might be necessary to remove (as he phrases it) the obstacles to the progress of younger communities created by the action of older and wealthier nations. But it seems probable that the influence of List's writings, added to his own deep-rooted and hereditary jealousy and dislike of English predominance, had something to do with his change of attitude.

The practical conclusion at which he thus arrived, though it is by no means in contradiction to the doctrine of the existence of natural economic laws, accords but ill with his optimistic scheme; and another economist, accepting his fundamental ideas, applied himself to remove the foreign accretion, as he regarded it, and to preach the theory of spontaneous social harmonies in relation with the practice of free trade as its legitimate outcome.

**Bastiat.** Frédéric Bastiat (1801–1850), though not a profound thinker, was a brilliant and popular writer on economic questions. Though he always had an inclination for such studies, he was first impelled to the active propagation of his views by his earnest sympathy with the English

anti-corn-law agitation. Naturally of an ardent temperament, he threw himself with zeal into the free-trade controversy, through which he hoped to influence French economic policy, and published in 1845 a history of the struggle under the title of *Cobden et la Ligue*. In 1845–48 appeared his *Sophismes Économiques* (Eng. trans. by P. J. Stirling, 1873), in which he exhibited his best qualities of mind. Though Cairnes goes too far in comparing this work with the *Lettres Provinciales*, it is certainly marked by much liveliness, point, and vigour. But to expose the absurdities of the ordinary protectionism was no difficult task; it is only in such a form as the doctrine assumed in the hands of List, as a purely provisional and preparatory scheme, that it deserves and demands consideration. After the revolution of 1848, which for a time put an end to the free-trade movement in France, the efforts of Bastiat were directed against the socialists. Besides several minor pieces possessing the same sort of merit as the *Sophismes*, he produced, with a view to this controversy, his most ambitious as well as characteristic work, the *Harmonies Économiques* (Eng. trans. by P. J. Stirling, 1860). Only the first volume was published; it appeared in 1850, and its author died in the same year. Since then the notes and sketches which he had prepared as materials towards the production of the second volume have been given to the public in the collected edition of his writings (by Paillottet, with Life by Fontenay, 7 vols.), and we can thus gather what would have been the spirit and substance of the later portions of the book.

It will always be historically interesting as the last incarnation of thorough-going economic optimism. This optimism, recurring to its first origin, sets out from theological considerations, and Bastiat is commended by his English translator for treating political economy "in connexion with final causes." The spirit of the work is to represent "all principles, all motives, all springs of action, all interests, as co-operating towards a grand final result which humanity will never reach, but to which it will always increasingly tend, namely, the indefinite approximation of all classes towards a level, which steadily rises,—in other words, the equalization of individuals in the general amelioration."

What claimed to be novel and peculiar in his scheme was principally his theory of value. Insisting on the idea that value does not denote anything inherent in the objects to which it is attributed, he endeavoured to show that it never signifies anything but the ratio of two "services." This view he develops with great variety and felicity of illustration. Only the mutual services of human beings, according to him, possess value and can claim a retribution; the assistance given by nature to the work of production is always purely gratuitous, and never enters into price. Economic progress, as, for example, the improvement and larger use of machinery, tends perpetually to transfer more and more of the elements of utility from the domain of property, and therefore of value, into that of community, or of universal and unpurchased enjoyment. It will be observed that this theory is substantially identical with Carey's, which had been earlier propounded; and the latter author in so many words alleges it to have been taken from him without acknowledgment. It has not perhaps been sufficiently attended to that very similar views are found in Dunoyer, of whose work Bastiat spoke as exercising a powerful influence on "the restoration of the science," and whom Fontenay, the biographer of Bastiat, tells us he recognized as one of his masters, Charles Comte being the other.

The mode which has just been explained of conceiving industrial action and industrial progress is interesting and instructive so far as it is really applicable, but it was unduly generalized. Cairnes has

<sup>1</sup> It is, however, a mistake to suppose that the assumption of this historical order of descent is essential to the theory in question.

<sup>2</sup> This argument seems scarcely met by Prof. F. A. Walker, *Political Economy*, 50–52. But perhaps he is right in thinking that Carey exaggerates the importance of the considerations on which it is founded. Mill and Leslie remark that the transportation of agricultural products from the western to the Atlantic States has the same effect as their export to Europe, so far as this so-called "land-butchery" is concerned; besides, some manures are obtainable from abroad.

well pointed out that Bastiat's theoretic soundness was injuriously affected by his habit of studying doctrines with a direct view to contemporary social and political controversies. He was thus predisposed to accept views which appeared to lend a sanction to legitimate and valuable institutions, and to reject those which seemed to him to lead to dangerous consequences. His constant aim is, as he himself expressed it, to "break the weapons" of antisocial reasoners "in their hands," and this preoccupation interferes with the single-minded effort towards the attainment of scientific truth. The creation or adoption of his theory of value was inspired by the wish to meet the socialistic criticism of property in land; for the exigencies of this controversy it was desirable to be able to show that nothing is ever paid for except personal effort. His view of rent was, therefore, so to speak, foreordained, though it may have been suggested, as indeed the editor of his posthumous fragments admits, by the writings of Carey. He held, with the American writer, that rent is purely the reward of the pains and expenditure of the landlord or his predecessors in the process of converting the natural soil into a *farm* by clearing, draining, fencing, and the other species of permanent improvements.<sup>1</sup> He thus gets rid of the (so-called) Ricardian doctrine, which was accepted by the socialists, and by them used for the purpose of assailing the institution of landed property, or, at least, of supporting a claim of compensation to the community for the appropriation of the land by the concession of the "right to labour." As Cairnes has said, "what Bastiat did was this: having begun at infinite pains to exclude gratuitous gifts of nature from the possible elements of value, and pointedly identified [rather, associated] the phenomenon with 'human effort' as its exclusive source, he designates human effort by the term 'service,' and then employs this term to admit as sources of value those very gratuitous natural gifts the exclusion of which in this capacity constituted the essence of his doctrine." The justice of this criticism will be apparent to any one who considers the way in which Bastiat treats the question of the value of a diamond. That what is paid for in most cases of human dealings is *effort* no one can dispute. But it is surely a *reductio ad absurdum* of his theory of value, regarded as a doctrine of universal application, to represent the price of a diamond which has been accidentally found as remuneration for the effort of the finder in appropriating and transmitting it. And, with respect to land, whilst a large part of rent, in the popular sense, must be explained as interest on capital, it is plain that the native powers of the soil are capable of appropriation, and that then a price can be demanded and will be paid for their use.

Bastiat is weak on the philosophical side; he is filled with the ideas of theological teleology, and is led by these ideas to form *a priori* opinions of what existing facts and laws must necessarily be. And the *jus naturæ*, which, like metaphysical ideas generally, has its root in theology, is as much a postulate with him as with the physiocrats. Thus, in his essay on *Free Trade*, he says:—"Exchange is a natural right like property. Every citizen who has created or acquired a product ought to have the option of either applying it immediately to his own use or ceding it to whosoever on the surface of the globe consents to give him in exchange the object of his desires." Something of the same sort had been said by Turgot; and in his time this way of regarding things was excusable, and even provisionally useful; but in the middle of the 19th century it was time that it should be seen through and abandoned.

Bastiat had a real enthusiasm for a science which he thought destined to render great services to mankind, and he seems to have believed intensely the doctrines which gave a special colour to his teaching. If his optimistic exaggerations favoured the propertied classes, they certainly were not prompted by self-interest or servility. But they are exaggerations; and, amidst the modern conflicts of capital and labour, his perpetual assertion of social harmonies is the cry of peace, peace, where there is no peace. The freedom of industry, which he treated as a sort of panacea, has undoubtedly brought with it great benefits; but a sufficient experience has shown that it is inadequate to solve the social problem. How can the advocates of economic revolution be met by assuring them that every-

<sup>1</sup> M. Lerooy-Beaulieu has recently maintained (*Essai sur la Répartition des Richesses*, 2d ed., 1882) that this, though not strictly, is approximately true.—that economic forms a very small part of actual rent.

thing in the natural economy is harmonious—that, in fact, all they seek for already exists? A certain degree of spontaneous harmony does indeed exist, for society could not continue without it, but it is imperfect and precarious; the question is, How can we give to it the maximum of completeness and stability?

Augustin Cournot (1801–1877) appears to have been the first (the German, H. H. Gossen, praised by Jevons, wrote in 1854) who, with a competent knowledge of both subjects, endeavoured to apply mathematics to the treatment of economic questions. His treatise entitled *Recherches sur les Principes Mathématiques de la Théorie des Richesses* was published in 1838. He mentions in it only one previous enterprise of the same kind (though there had in fact been others)—that, namely, of Nicolas François Canard, whose book, published in 1802, was crowned by the Institute, though "its principles were radically false as well as erroneously applied." Notwithstanding Cournot's just reputation as a writer on mathematics, the *Recherches* made little impression. The truth seems to be that his results are in some cases of little importance, in others of questionable correctness, and that, in the abstractions to which he has recourse in order to facilitate his calculations, an essential part of the real conditions of the problem is sometimes omitted. His pages abound in symbols representing unknown functions, the form of the function being left to be ascertained by observation of facts, which he does not regard as a part of his task, or only some known properties of the undetermined function being used as bases for deduction. Jevons includes in his list of works in which a mathematical treatment of economics is adopted a second treatise which Cournot published in 1863, with the title *Principes de la Théorie des Richesses*. But in reality, in the work so named, which is written with great ability, and contains much forcible reasoning in opposition to the exaggerations of economic optimists, the mathematical method is abandoned, and there is not an algebraical formula in the book. The author admits that the public has always shown a repugnance to the use of mathematical symbols in economic discussion, and, though he thinks they might be of service in facilitating exposition, fixing the ideas, and suggesting further developments, he acknowledges that a grave danger attends their use. The danger, according to him, consists in the probability that an undue value may be attached to the abstract hypotheses from which the investigator sets out, and which enable him to construct his formulæ. And his practical conclusion is that mathematical processes should be employed only with great precaution, or even not employed at all if the public judgment is against them, for "this judgment," he says, "has its secret reasons, almost always more sure than those which determine the opinions of individuals." It is an obvious consideration that the acceptance of unsound or one-sided abstract principles as the premises of argument does not depend on the use of mathematical forms, though it is possible that the employment of the latter may by association produce an illusion in favour of the certainty of those premises. But the great objection to the use of mathematics in economic reasoning is that it is necessarily sterile. If we examine the attempts which have been made to employ it, we shall find that the fundamental conceptions on which the deductions are made to rest are vague, indeed metaphysical, in their character. Units of animal or moral satisfaction, of utility, and the like are as foreign to positive science as a unit of dormitive faculty would be; and a unit of value, unless we understand by value the quantity of one commodity exchangeable under given conditions for another, is an equally indefinite idea. Mathematics can indeed formulate ratios of exchange when they have once been

observed; but it cannot by any process of its own determine those ratios, for quantitative conclusions imply quantitative premises, and these are wanting. There is then no future for this kind of study, and it is only waste of intellectual power to pursue it. But the importance of mathematics as an educational introduction to all the higher orders of research is not affected by this conclusion. The study of the physical medium, or environment, in which economic phenomena take place, and by which they are affected, requires mathematics as an instrument; and nothing can ever dispense with the didactic efficacy of that science, as supplying the primordial type of rational investigation, giving the lively sentiment of decisive proof, and disengaging the mind to illusory conceptions and sophistical combinations. And a knowledge of at least the fundamental principles of mathematics is necessary to economists to keep them right in their statements of doctrine, and prevent their enunciating propositions which have no definite meaning. Even distinguished writers sometimes betray a serious deficiency in this respect; thus they assert that one quantity "varies inversely as" another, when what is meant is that the sum (not the product) of the two is constant; and they treat as capable of numerical estimation the amount of an aggregate of elements which, differing in kind, cannot be reduced to a common standard. As an example of the latter error, it may be mentioned that "quantity of labour," so often spoken of by Ricardo, and in fact made the basis of his system, includes such various species of exertion as will not admit of summation or comparison.

*Italy.*—The first Italian translation of the *Wealth of Nations* appeared in 1780. The most distinguished Italian economist of the period here dealt with was, however, no disciple of Smith. This was Melchiorre Gioja, author, besides statistical and other writings, of a voluminous work entitled *Nuovo Prospetto delle Scienze Economiche* (6 vols., 1815–17; the work was never completed), intended to be an encyclopædia of all that had been taught by theorists, enacted by Governments, or effected by populations in the field of public and private economy. It is a learned and able treatise, but so overlaid with quotations and tables as to repel rather than attract readers. Gioja admired the practical economic system of England, and enlarges on the advantages of territorial properties, manufactures, and mercantile enterprises on the large as opposed to the small scale. He defends a restrictive policy, and insists on the necessity of the action of the state as a guiding, supervising, and regulating power in the industrial world. But he is in full sympathy with the sentiment of his age against ecclesiastical domination and other mediæval survivals. We can but very briefly notice Romagnosi (d. 1835), who, by his contributions to periodical literature, and by his personal teaching, greatly influenced the course of economic thought in Italy; Antonio Scialoja (*Principii d'Economia Sociale*, 1840; and *Carestia e Governo*, 1853), an able advocate of free trade (d. 1877); Luigi Cibrario, well known as the author of *Economia Politica del medio evo* (1839; 5th ed. 1861; French trans. by Barneaud, 1859), which is in fact a view of the whole social system of that period; Girolamo Boccardo (b. 1829; *Trattato Teorico-pratico di Economia politica*, 1853); the brilliant controversialist Francesco Ferrara, professor at Turin from 1849 to 1858 (in whose school most of the present Italian teachers of the science were, directly or indirectly, educated), a partisan of the *laissez faire* doctrine in its most extreme form, and an advocate of the peculiar opinions of Carey and Bastiat on the subject of rent; and, lastly, the Neapolitan minister Ludovico Bianchini (*Principii della Scienza del Ben Vivere Sociale*, 1845 and 1855), who is remarkable as having followed in some

degree an historical direction, and asserted the principle of relativity, and who also dwelt on the relations of economics with morals, by a due attention to which the Italian economists have, indeed, in general been honourably distinguished.

*Spain.*—The *Wealth of Nations* was translated into Jovel-Spanish by Ortiz in 1794. It may perhaps have influenced Gaspar de Jovellanos, who in 1795 presented to the council of Castile and printed in the same year his celebrated *Informe de la Sociedad Economica de Madrid en expediente de Ley Agraria*, which was a powerful plea for reform, especially in taxation and the laws affecting agriculture, including those relating to the systems of entail and mortmain. An English version of this memoir is given in the translation (1809) of Laborde's *Spain*, vol. iv.

*Germany.*—Roscher observes that Smith did not at first produce much impression in Germany.<sup>1</sup> He does not appear to have been known to Frederick the Great; he certainly exercised no influence on him. Nor did Joseph II. take notice of his work. And of the minor German princes, Karl Friedrich of Baden, as a physiocrat, would not be accessible to his doctrines. It was otherwise in the generation whose principal activity belongs to the first decade of the 19th century. The Prussian statesmen who were grouped round Stein had been formed as economists by Smith, as had also Gentz, intellectually the most important man of the Metternich régime in Austria.

The first German expositors of Smith who did more than merely reproduce his opinions were Christian Jacob Kraus (1753–1807), Georg Sartorius (1766–1828), and August Ferdinand Laidner (1760–1819). They contributed independent views from different standpoints,—the first from that of the effect of Smith's doctrine on practical government, the second from that of its bearing on history, the third from that of its relation to statistics. Somewhat latter came Gottlieb Hufeland (1760–1817), Johann Friedrich Eusebius Lotz (1771–1838), and Ludwig Heinrich von Jakob (1759–1827), who, whilst essentially of the school of Smith, apply themselves to a revision of the fundamental conceptions of the science. These authors did not exert anything like the wide influence of Say, partly on account of the less attractive form of their writings, but chiefly because Germany had not then, like France, a European audience. Julius von Soden (1754–1831) is largely founded on Smith, whom, however, he criticizes with undue severity, especially in regard to his form and arrangement; the *Wealth of Nations* he describes as a series of precious fragments, and censures Smith for the absence of a comprehensive view of his whole subject, and also as one-sidedly English in his tendencies.

The highest form of the Smithian doctrine in Germany is represented by four distinguished names:—Karl Heinrich Rau (1792–1870), Friedrich Nebenius (1784–1857), Friedrich Benedict Wilhelm Hermann (1795–1868), and Johann Heinrich von Thünen (1783–1850).

Rau's characteristic is "erudite thoroughness." His *Lehrbuch* Ran. (1826–32) is an encyclopædia of all that up to his time had appeared in Germany under the several heads of *Volkswirtschaftslehre*, *Volkswirtschaftspolitik*, and *Finanzwissenschaft*. His book is rich in statistical observations, and is particularly instructive on the economic effects of different geographical conditions. It is well adapted for the teaching of public servants whose duties are connected with economics, and it has in fact been the source from which the German official world down to the present time has derived its knowledge of the science. In his earlier period Rau had insisted on the necessity of a reform of economic doctrine (*Ansichten der Volkswirtschaft*, 1821), and had tended towards relativity and the historical method; but he afterwards conceived the mistaken notion that that method "only looked into the past without studying the means of improving the present," and became himself purely practical in the narrower sense of that word. He has the merit of having given a separate treatment of *Unternehmer-gewinn*, or wages of management. The Prussian minister Nebenius, who was largely instrumental in the foundation of the Zollverein, was author of a highly esteemed monograph on public credit (1820). The *Staatswirtschaftliche Untersuchungen* (1832;

<sup>1</sup> The first German version of the *Wealth of Nations* was that by Johann Friedrich Schiller, published 1776–78. The second, which is the first good one, was by Christian Garve (1794, and again 1799 and 1810). A recent one by C. W. Asher (1861) is highly commended.

Hermann. 2d ed., 1870) of Hermann do not form a regular system, but treat a series of important special subjects. His rare technological knowledge gave him a great advantage in dealing with some economic questions. He reviewed the principal fundamental ideas of the science with great thoroughness and acuteness. "His strength," says Roscher, "lies in his clear, sharp, exhaustive distinction between the several elements of a complex conception, or the several steps comprehended in a complex act." For keen analytical power his German brethren compare him with Ricardo. But he avoids several one-sided views of the English economist. Thus he places public spirit beside egoism as an economic motor, regards price as not measured by labour only but as a product of several factors, and habitually contemplates the consumption of the labourer, not as a part of the cost of production to the capitalist, but as the main practical end of economies. Von Thünen is known principally by his remarkable work entitled *Der Isolierte Staat in Beziehung auf Landwirtschaft und Nationalökonomie* (1826; 2d ed., 1842). In this treatise, which is a classic in the political economy of agriculture, there is a rare union of exact observation with creative imagination. With a view to exhibit the natural development of agriculture, he imagines a state, isolated from the rest of the world, circular in form and of uniform fertility, without navigable rivers or canals, with a single large city at its centre, which supplies it with manufactures and receives in exchange for them its food-products, and proceeds to study the effect of distance from this central market on the agricultural economy of the several concentric spaces which compose the territory. The method, it will be seen, is highly abstract, but, though it may not be fruitful, it is quite legitimate. The author is under no illusion blinding him to the unreality of the hypothetical case. The supposition is necessary, in his view, in order to separate and consider apart one essential condition—that, namely, of situation with respect to the market. It was his intention (imperfectly realized, however) to institute afterwards several different hypotheses in relation to his isolated state, for the purpose of similarly studying other conditions which in real life are found in combination or conflict. The objection to this method lies in the difficulty of the return from the abstract study to the actual facts; and this is probably an insuperable one in regard to most of its applications. The investigation, however, leads to trustworthy conclusions as to the conditions of the succession of different systems of land economy. The book abounds in calculations relating to agricultural expenditure and income, which diminish its interest to the general reader, though they are considered valuable to the specialist. They embody the results of the practical experience of the author on his estate of Tellow in Mecklenburg-Schwerin. Von Thünen was strongly impressed with the danger of a violent conflict between the middle class and the proletariat, and studied earnestly the question of wages, which he was one of the first to regard, not merely as the price of the commodity labour, but as the means of subsistence of the mass of the community. He arrived by mathematical reasonings of some complexity at a formula which expresses the amount of "natural wages" as  $= \sqrt{ap}$ , where  $a$  is the necessary expenditure of the labourer for subsistence, and  $p$  is the product of his labour. To this formula he attributed so much importance that he directed it to be engraved on his tomb. It implies that wages ought to rise with the amount of the product; and this conclusion led him to establish on his estate a system of participation by the labourers in the profits of farming, of which some account will be found in Mr Sedley Taylor's *Profit-sharing between Capital and Labour* (1884). Von Thünen deserves more attention than he has received in England; both as a man and as a writer he was eminently interesting and original; and there is much in *Der Isolierte Staat* and his other works that is awakening and suggestive.

Storch.

Roscher recognizes what he calls a Germano-Russian (deutsch-russische) school of political economy, represented principally by Heinrich Storch (1766–1825). Mercantilist principles had been preached by a native ("autochthonen") economist, Ivan Possoschkoff, in the time of Peter the Great. The new ideas of the Smithian system were introduced into Russia by Christian von Schlözer (1774–1831) in his professorial lectures and in his *Anfangsgründe der Staatswirtschaft, oder die Lehre von National-reichtume* (1805–1807). Storch was instructor in economic science of the future emperor Nicholas and his brother the grand-duke Michael, and the substance of his lessons to them is contained in his *Cours d'Économie Politique* (1815). The translation of this treatise into Russian was prevented by the censorship; Rau published a German version of it, with annotations, in 1819. It is a work of a very high order of merit. The epithet "deutsch-russisch" seems little applicable to Storch; as Roscher himself says, he

follows mainly English and French writers—Say, Sismondi, Turgot, Bentham, Stuart, and Hume, but, above all, Adam Smith. His personal position (and the same is true of Schlözer) led him to consider economic doctrines in connexion with a stage of culture different from that of the Western populations amongst which they had been formulated; this change of the point of view opened the door to relativity, and helped to prepare the historical method. Storch's study of the economic and moral effects of serfdom is regarded as especially valuable. The general subjects with which he has particularly connected his name are (1) the doctrine of immaterial commodities (or elements of national prosperity), such as health, talent, morality, and the like; (2) the question of "productive" and "unproductive," as characters of labour and of consumption, on which he disagreed with Smith and may have furnished indications to Dunoyer; and (3) the differences between the revenue of nations and that of individuals, on which he follows Lauderdale and is opposed to Say. The latter economist having published at Paris (1823) a new edition of Storch's *Cours*, with criticisms sometimes offensive in tone, he published by way of reply to some of Say's strictures what is considered his ripest and scientifically most important work, *Considérations sur la nature du Revenu National* (1824; translated into German by the author himself, 1825).

A distinct note of opposition to the Smithian economics was sounded in Germany by two writers, who, setting out from somewhat different points of view, animated by different sentiments, and favouring different practical systems, yet, so far as their criticisms are concerned, arrive at similar conclusions; we mean Adam Müller and Friedrich List.

Adam Müller (1779–1829) was undoubtedly a man of real genius. In his principal work *Elemente der Staatskunst* (1809), and his other writings, he represents a movement of economic thought which was in relation with the (so-called) Romantic literature of the period. The reaction against Smithianism of which he was the coryphæus was founded on an attachment to the principles and social system of the Middle Ages. It is possible that the political and historical ideas which inspire him, his repugnance to contemporary liberalism, and his notions of regular organic development, especially in relation to England, were in some degree imbibed from Edmund Burke, whose *Reflections on the Revolution in France* had been translated into German by Friedrich Gentz, the friend and teacher of Müller. The association of his criticisms with mediæval prepossessions ought not to prevent our recognizing the elements of truth which they contain.

He protests against the doctrine of Smith and against modern political economy in general on the ground that it presents a mechanical, atomistic, and purely material conception of society, that it reduces to nullity all moral forces and ignores the necessity of a moral order, that it is at bottom no more than a theory of private property and private interests, and takes no account of the life of the people as a whole in its national solidarity and historical continuity. Exclusive attention, he complains, is devoted to the immediate production of exchange value and to the transitory existence of the individual, to the maintenance of the collective production for future generations, to intellectual products, powers, possessions, and enjoyments, and to the state with its higher tasks and aims, scarcely a thought is given. The truth is that nations are specialized organisms with distinct principles of life, having definite individualities which determine the course of their historical development. Each is through all time one whole; and, as the present is the heir of the past, it ought to keep before it constantly the permanent good of the community in the future. The economic existence of a people is only one side or province of its entire activity, requiring to be kept in harmony with the higher ends of society; and the proper organ to effect this reconciliation is the state, which, instead of being merely an apparatus for the administration of justice, represents the totality of the national life. The division of labour, Müller holds, is imperfectly developed

by Smith, who makes it to arise out of a native bent for truck or barter; whilst its dependence on capital—on the labours and accumulations of past generations—is not duly emphasized, nor is the necessary counterpoise and completion of the division of labour, in the principle of the national combination of labour, properly brought out. Smith recognizes only material, not spiritual, capital; yet the latter, represented in every nation by language, as the former by money, is a real national store of experience, wisdom, good sense, and moral feeling, transmitted with increase by each generation to its successor, and enables each generation to produce immensely more than by its own unaided powers it could possibly do. Again, the system of Smith is one-sidedly British; if it is innocuous on the soil of England, it is because in her society the old foundations on which the spiritual and material life of the people can securely rest are preserved in the surviving spirit of feudalism and the inner connexion of the whole social system—the national capital of laws, manners, reputation, and credit, which has been landed down in its integrity in consequence of the insular position of the country. For the continent of Europe a quite different system is necessary, in which, in place of the sum of the private wealth of individuals being viewed as the primary object, the real wealth of the nation and the production of national power shall be made to predominate, and along with the division of labour its national union and concentration—along with the physical, no less the intellectual and moral, capital shall be embraced. In these leading traits of Müller's thought there is much which foreshadows the more recent forms of German economic and sociological speculation, especially those characteristic of the "Historical" school.

List.

Another element of opposition was represented by Friedrich List (1798-1846), a man of great intellectual vigour as well as practical energy, and notable as having powerfully contributed by his writings to the formation of the German Zollverein. His principal work is entitled *Das Nationale System der Politischen Oekonomie* (1811; 6th ed., 1877). Though his practical conclusions were different from Müller's, he was largely influenced by the general mode of thinking of that writer, and by his strictures on the doctrine of Smith. It was particularly against the co-mopolitan principle in the modern economical system that he protested, and against the absolute doctrine of free trade, which was in harmony with that principle. He gave prominence to the national idea, and insisted on the special requirements of each nation according to its circumstances and especially to the degree of its development.

He refuses to Smith's system the title of the industrial, which he thinks more appropriate to the mercantile system, and designates the former as "the exchange-value system." He denies the parallelism asserted by Smith between the economic conduct proper to an individual and to a nation, and holds that the immediate private interest of the separate members of the community will not lead to the highest good of the whole. The nation is an existence, standing between the individual and humanity, and formed into a unity by its language, manners, historical development, culture, and constitution. This unity is the first condition of the security, wellbeing, progress, and civilization of the individual; and private economic interests, like all others, must be subordinated to the maintenance, completion, and strengthening of the nationality. The nation having a continuous life, its true wealth consists—and this is List's fundamental doctrine—not in the quantity of exchange-values which it possesses, but in the full and many-sided development of its productive powers. Its economic education, if we may so speak, is more important than the immediate production of values, and it may be right that the present generation should sacrifice its gain and enjoyment to secure the strength and skill of the future. In the sound and normal condition of a nation which has attained economic maturity, the three productive powers of agriculture, manufactures, and commerce should be alike developed. But the two latter factors are superior in importance, as exercising a more effective and fruitful influence on the whole culture of the nation, as well as on its independence. Navigation, railways, all higher technical arts, connect themselves specially with these factors; whilst in a purely agricultural state there is a tendency to stagnation, absence of enterprise, and the maintenance of antiquated prejudices. But for the growth of the higher forms of industry all countries are not adapted—only those of the temperate zones, whilst the torrid regions have a natural monopoly in the production of certain raw materials; and thus between these two groups of countries a division of labour and confederation of powers spontaneously takes place. List then goes on to explain his theory

of the stages of economic development through which the nations of the temperate zone, which are furnished with all the necessary conditions, naturally pass, in advancing to their normal economic state. These are (1) pastoral life, (2) agriculture, (3) agriculture united with manufactures; whilst in the final stage agriculture, manufactures, and commerce are combined. The economic task of the state is to bring into existence through legislative and administrative action the conditions required for the progress of the nation through these stages. Out of this view arises List's scheme of industrial politics. Every nation, according to him, should begin with free trade, stimulating and improving its agriculture by intercourse with richer and more cultivated nations, importing foreign manufactures and exporting raw products. When it is economically so far advanced that it can manufacture for itself, then a system of protection should be employed to allow the home industries to develop themselves fully, and save them from being overpowered in their earlier efforts by the competition of more matured foreign industries in the home market. When the national industries have grown strong enough no longer to dread this competition, then the highest stage of progress has been reached; free trade should again become the rule, and the nation be thus thoroughly incorporated with the universal industrial union. In List's time, according to his view, Spain, Portugal, and Naples were purely agricultural countries; Germany and the United States of North America had arrived at the second stage, their manufactures being in process of development; France was near the boundary of the third or highest stage, which England alone had reached. For England, therefore, as well as for the agricultural countries first named, free trade was the right economic policy, but not for Germany or America. What a nation loses for a time in exchange values during the protective period she much more than gains in the long run in productive power,—the temporary expenditure being strictly analogous, when we place ourselves at the point of view of the life of the nation, to the cost of the industrial education of the individual. The practical conclusion which List drew for his own country was that she needed for her economic progress an extended and conveniently bounded territory reaching to the sea-coast both on north and south, and a vigorous expansion of manufactures and commerce, and that the way to the latter lay through judicious protective legislation with a customs union comprising all German lands, and a German marine with a Navigation Act. The national German spirit, striving after independence and power through union, and the national industry, awaking from its lethargy and eager to recover lost ground, were favourable to the success of List's look, and it produced a great sensation. He ably represented the tendencies and demands of his time in his own country; his work had the effect of fixing the attention, not merely of the speculative and official classes, but of practical men generally, on questions of political economy; and he had without doubt an important influence on German industrial policy. So far as science is concerned, the emphasis he laid on the relative historical study of stages of civilization as affecting economic questions, and his protest against absolute formulas, had a certain value; and the preponderance given to the national development over the immediate gains of individuals was sound in principle; though his doctrine was, both on its public and private sides, too much of a mere euhemeristic, and tended in fact to set up a new form of mercantilism, rather than to aid the contemporary effort towards social reform.

Most of the writers at home or abroad hitherto mentioned continued the traditions of the school of Smith, only developing his doctrine in particular directions, sometimes not without one-sidedness or exaggeration, or correcting minor errors into which he had fallen, or seeking to give to the exposition of his principles more of order and lucidity. Some assailed the abuse of abstraction by Smith's successors, objected to the conclusions of Ricardo and his followers their non-accordance with the actual facts of human life, or protested against the anti-social consequences which seemed to result from the application of the (so-called) orthodox formulas. A few challenged Smith's fundamental ideas, and insisted on the necessity of altering the basis of general philosophy on which his economics ultimately rest. But, notwithstanding various premonitory indications, nothing substantial, at least nothing effective, was done, within the field we have as yet surveyed, towards the establishment of a really new order of thinking, or new mode of proceeding, in this branch of inquiry. Now, however, we have to describe a great and growing movement, which has already considerably changed the whole character of the study in the conceptions of

many, and which promises to exercise a still more potent influence in the future. We mean the rise of the Historical School, which we regard as marking the third epoch in the modern development of economic science.

#### THE HISTORICAL SCHOOL.

The negative movement which filled the 18th century had for its watchword on the economic side the liberation of industrial effort from both feudal survivals and Governmental fetters. But in all the aspects of that movement, the economic as well as the rest, the process of demolition was historically only the necessary preliminary condition of a total renovation, towards which western Europe was energetically tending, though with but an indistinct conception of its precise nature. The disorganization of the body of opinion which underlay the old system outran the progress towards the establishment of new principles adequate to form a guidance in the future. The critical philosophy which had wrought the disorganization could only repeat its formulas of absolute liberty, but was powerless for reconstruction. And hence there was seen throughout the West, after the French explosion, the remarkable spectacle of a continuous oscillation between the tendency to recur to outworn ideas and a vague impulse towards a new order in social thought and life, this impulse often taking an anarchical character.

From this state of oscillation, which has given to our century its equivocal and transitional aspect, the only possible issue was in the foundation of a scientific social doctrine which should supply a basis for the gradual convergence of opinion on human questions. The foundation of such a doctrine is the immortal service for which the world is indebted to Auguste Comte.

Comte.

The leading features of sociology, as he conceived it, are the following:—(1) it is essentially *one* science, in which all the elements of a social state are studied in their relations and mutual actions; (2) it includes a dynamical as well as a statical theory of society; (3) it thus eliminates the absolute, substituting for an imagined fixity the conception of ordered change; (4) its principal method, though others are not excluded, is that of historical comparison; (5) it is pervaded by moral ideas, by notions of social duty, as opposed to the individual rights which were derived as corollaries from the *jus naturæ*; and (6) in its spirit and practical consequences it tends to the realization of all the great ends which compose "the popular cause"; yet (7) it aims at this through peaceful means, replacing revolution by evolution. The several characteristics we have enumerated are not independent; they may be shown to be vitally connected with each other. Several of these features must now be more fully described; the others will meet us before the close of the present survey.

In the masterly exposition of sociological method which is contained in the fourth volume of the *Philosophie Positive* (1839),<sup>1</sup> Comte marks out the broad division between social statics and social dynamics—the former studying the laws of social coexistence, the latter those of social development. The fundamental principle of the former is the general consensus between the several social organs and functions, which, without unduly pressing a useful analogy, we may regard as resembling that which exists between the several organs and functions of an animal body. The study of dynamical is different from, and necessarily subordinated to, that of statical sociology, progress being in fact the development of order, just as the study of evolution in biology is different from, and subordinated to, that of the structures and functions

which are exhibited by evolution as they exist at the several points of an ascending scale. The laws of social co-existence and movement are as much subjects for observation as the corresponding phenomena in the life of an individual organism. For the study of development in particular, a modification of the comparative method familiar to biologists will be the appropriate mode of research. The several successive stages of society will have to be systematically compared, in order to discover their laws of sequence, and to determine the filiation of their characteristic features.

Though we must take care that both in our statical and dynamical studies we do not ignore or contradict the fundamental properties of human nature, the project of deducing either species of laws from those properties independently of direct observation is one which cannot be realized. Neither the general structure of human society nor the march of its development could be so predicted. This is especially evident with respect to dynamical laws, because, in the passage of society from one phase to another, the preponderating agency is the accumulated influence of past generations, which is much too complex to be investigated deductively—a conclusion which it is important to keep steadily before us now that some of the (so-called) anthropologists are seeking to make the science of society a mere annex and derivative of biology. The principles of biology unquestionably lie at the foundation of the social science, but the latter has, and must always have, a field of research and a method of inquiry peculiar to itself. The field is history in the largest sense, including contemporary fact; and the principal, though not exclusive, method is, as we have said, that process of sociological comparison which is most conveniently called the historical method.

These general principles affect the economic no less than other branches of social speculation; and with respect to that department of inquiry they lead to important results. They show that the idea of forming a true theory of the economic frame and working of society apart from its other sides is illusory. Such study is indeed provisionally indispensable, but no rational theory of the economic organs and functions of society can be constructed if they are considered as isolated from the rest. In other words, a separate economic science is, strictly speaking, an impossibility, as representing only one portion of a complex organism, all whose parts and their actions are in a constant relation of correspondence and reciprocal modification. Hence, too, it will follow that, whatever useful indications may be derived from our general knowledge of individual human nature, the economic structure of society and its mode of development cannot be deductively foreseen, but must be ascertained by direct historical investigation. We have said "its mode of development"; for it is obvious that, as of every social element, so of the economic factor in human affairs, there must be a dynamical doctrine, a theory of the successive phases of the economic condition of society; yet in the accepted systems this was a desideratum, nothing but some partial and fragmentary notions on this whole side of the subject being yet extant. And, further, the economic structure and working of one historic stage being different from those of another, we must abandon the idea of an absolute system possessing universal validity, and substitute that of a series of such systems, in which, however, the succession is not at all arbitrary, but is itself regulated by law.

Though Comte's enterprise was a constructive one, his aim being the foundation of a scientific theory of society, he could not avoid criticizing the labours of those who before him had treated several branches of social inquiry. Amongst them the economists were necessarily considered;

<sup>1</sup> He had already in 1822 stated his fundamental principles in an opusculum which is reproduced in the Appendix to his *Politique Positive*.

and he urged or implied, in various places of his above-named work, as well as of his *Politique Positive*, objections to their general ideas and methods of procedure essentially the same with those which we stated in speaking of Ricardo and his followers. J. S. Mill shows himself much irritated by these comments, and remarks on them as showing "how extremely superficial M. Comte" (whom he yet regards as a thinker quite comparable with Descartes and Leibnitz) "could sometimes be,"—an unfortunate observation, which he would scarcely have made if he could have foreseen the subsequent march of European thought, and the large degree in which the main points of Comte's criticism have been accepted or independently reproduced.

*Germany.*—The second manifestation of this new movement in economic science was the appearance of the German historical school. The views of this school do not appear to have arisen, like Comte's theory of sociological method, out of general philosophic ideas; they seem rather to have been suggested by an extension to the economic field of the conceptions of the historical school of jurisprudence of which Savigny was the most eminent representative. The juristic system is not a fixed social phenomenon, but is variable from one stage in the progress of society to another—it is in vital relation with the other coexistent social factors; and what is, in the jural sphere, adapted to one period of development is often unfit for another. These ideas were seen to be applicable to the economic system also; the relative point of view was thus reached, and the absolute attitude was found to be untenable. Cosmopolitanism in theory, or the assumption of a system equally true of every country, and what has been called perpetualism, or the assumption of a system applicable to every social stage, were alike discredited. And so the German historical school appears to have taken its rise.

Roscher. Omitting preparatory indications and undeveloped germs of doctrine, we must trace the origin of the school to Wilhelm Roscher. Its fundamental principles are stated, though with some hesitation, and with an unfortunate contrast of the historical with the "philosophical" method,<sup>1</sup> in his *Grundriss zu Vorlesungen über die Staatswirtschaft nach geschichtlicher Methode* (1843). The following are the leading heads insisted on in the preface to that work.

"The historical method exhibits itself not merely in the external form of a treatment of phenomena according to their chronological succession, but in the following fundamental ideas. (1) The aim is to represent what nations have thought, willed, and discovered in the economic field, what they have striven after and attained, and why they have attained it. (2) A people is not merely the mass of individuals now living; it will not suffice to observe contemporary facts. (3) All the peoples of whom we can learn anything must be studied and compared from the economic point of view, especially the ancient peoples, whose development lies before us in its totality. (4) We must not simply praise or blame economic institutions; but few of them have been salutary or detrimental to all peoples and at all stages of culture; rather it is a principal task of science to show how and why, out of what was once reasonable and beneficent, the unwise and inexpedient has often gradually arisen." Of the principles enunciated in this paraphrase of Roscher's words a portion of the third alone seems open to objection; the economy of ancient peoples is not a more important subject of study than that of the moderns; indeed the question of the relative importance of the two is one that ought not to be raised. For the essential condition of all sound sociologi-

cal inquiry is the comparative consideration of the entire series of the most complete evolution known to history—that, namely, of the group of nations forming what is known as the Occidental Commonwealth, or, more briefly, "the West." The reasons for choosing this social series, and for provisionally restricting our studies almost altogether to it, have been stated with unanswerable force by Comte in the *Philosophie Positive*. Greece and Rome are, indeed, elements in the series; but it is the development as a whole, not any special portions of it, that sociology must keep in view in order to determine the laws of the movement,—just as, in the study of biological evolution, no one stage of an organism can be considered as of preponderating importance, the entire succession of changes being the object of research. Of Roscher's further eminent services we shall speak hereafter; he is now mentioned only in relation to the origin of the new school.

In 1848 Bruno Hildebrand published the first volume of a work, which, though he lived for many years after (d. 1878), he never continued, entitled *Die Nationalökonomie der Gegenwart und Zukunft*. Hildebrand was a thinker of a really high order; it may be doubted whether amongst German economists there has been any endowed with a more profound and searching intellect. He is quite free from the wordiness and obscurity which too often characterize German writers, and traces broad outlines with a sure and powerful hand. His book contains a masterly criticism of the economic systems which preceded, or belonged to, his time, including those of Smith, Müller, List, and the socialists. But it is interesting to us at present mainly from the general position he takes up, and his conception of the real nature of political economy. The object of his work, he tells us, is to open a way in the economic domain to a thorough historical direction and method, and to transform the science into a doctrine of the laws of the economic development of nations. It is interesting to observe that the type which he sets before him in his proposed reform of political economy is not that of historical jurisprudence, but of the science of language as it has been reconstructed in the present century, a selection which indicates the comparative method as the one which he considered appropriate. In both sciences we have the presence of an ordered variation in time, and the consequent substitution of the relative for the absolute.

In 1853 appeared the work of Karl Knies, entitled *Die Knies. Politische Oekonomie vom Standpunkte der geschichtlichen Methode*. This is an elaborate exposition and defence of the historical method in its application to economic science, and is the most systematic and complete manifesto of the new school, at least on the logical side. The fundamental propositions are that the economic constitution of society at any epoch on the one hand, and on the other the contemporary theoretic conception of economic science, are results of a definite historical development; that they are both in vital connexion with the whole social organism of the period, having grown up along with it and under the same conditions of time, place, and nationality; that the economic system must therefore be regarded as passing through a series of phases correlative with the successive stages of civilization, and can at no point of this movement be considered to have attained an entirely definitive form; that no more the present than any previous economic organization of society is to be regarded as absolutely good and right, but only as a phase in a continuous historical evolution; and that in like manner the now prevalent economic doctrine is not to be viewed as complete and final, but only as representing a certain stage in the unfolding or progressive manifestation of the truth.

<sup>1</sup> This phraseology was probably borrowed from the controversy on the method of jurisprudence between Thibaut on the one hand and Savigny and Hugo on the other.

The theme of the book is handled with, perhaps, an undue degree of expansion and detail. The author exhibits much sagacity as well as learning, and criticizes effectively the errors, inconsistencies, and exaggerations of his predecessors. But in characterizing and vindicating the historical method he has added nothing to Comte. A second edition of his treatise was published in 1883, and in this he makes the singular confession that, when he wrote in 1852, the *Philosophie Positive*, the six volumes of which had appeared from 1830 to 1842, was entirely unknown to him and, he adds, probably to all German economists. This is not to the credit of their open-mindedness or literary vigilance, if we remember that Mill was already in correspondence with Comte in 1841, and that his eulogistic notice of him in the *Logic* appeared in 1843. When, however, Knies at a later period examined Comte's work, he was, he tells us, surprised at finding in it so many anticipations of, or "parallelisms" with, his own conclusions. And well he might; for all that is really valuable in his methodology is to be found in Comte, applied on a larger scale, and designed with the broad and commanding power which marks the *dei majores* of philosophy.

There are two points which seem to be open to criticism in the position taken by some German economists of the historical school.

1. Knies and some other writers, in maintaining the principle of relativity in economic theory, appear not to preserve the due balance in one particular. The two forms of absolutism in doctrine, cosmopolitanism and what Knies calls perpetualism, he seems to place on exactly the same footing; in other words, he considers the error of overlooking varieties of local circumstances and nationality to be quite as serious as that of neglecting differences in the stage of historical development. But this is certainly not so. In every branch of sociology the latter is much the graver error, vitiating radically, wherever it is found, the whole of our investigations. If we ignore the fact, or mistake the direction, of the social movement, we are wrong in the most fundamental point of all—a point, too, which is involved in every question. But the variations depending on difference of race, as affecting bodily and mental endowment, or on diversity of external situation, are secondary phenomena only; they must be postponed in studying the general theory of social development, and taken into account afterwards when we come to examine the modifications in the character of the development arising out of peculiar conditions. And, though the physical nature of a territory is a condition which is likely to operate with special force on economic phenomena, it is rather on the technical forms and comparative extension of the several branches of industry that it will act than on the social conduct of each branch, or the co-ordination and relative action of all, which latter are the proper subjects of the inquiries of the economist.

2. Some members of the school appear, in their anxiety to assert the relativity of the science, to fall into the error of denying economic laws altogether; they are at least unwilling to speak of "natural laws" in relation to the economic world. From a too exclusive consideration of law in the inorganic sphere, they regard this phraseology as binding them to the notion of fixity and of an invariable system of practical economy. But, if we turn our attention rather to the organic sciences, which are more kindred to the social, we shall see that the term "natural law" carries with it no such implication. As we have more than once indicated, an essential part of the idea of life is that of development, in other words, of "ordered change." And that such a development takes place in the constitution and working of society in all its elements is a fact which cannot be doubted, and which these writers themselves emphatically assert. That there exist between the several social elements such relations as make the change of one element involve or determine the change of another is equally plain; and why the name of natural laws should be denied to such constant relations of coexistence and succession it is not easy to see. These laws, being universal, admit of the construction of an abstract theory of economic development; whilst a part of the German historical school tends to substitute for such a theory a mere description of different national economies, introducing prematurely—as we have pointed out—the action of special territorial or ethnological conditions, instead of reserving this as the ground of later modifications, in concrete cases, of the primary general laws deduced from a study of the common human evolution.

To the three writers above named, Roscher, Hildebrand, and Knies, the foundation of the German historical school of political economy belongs. It does not appear that Roscher in his own subsequent labours has been much under the influence of the

method which he has in so many places admirably characterized. In his *System der Volkswirtschaft* (vol. i., *Grundlagen der Nationalökonomie*, 1854, 15th ed. 1880; vol. ii., *N. O. des Ackerbaues*, 1860, 10th ed. 1882; vol. iii., *N. O. des Handels und Genußflusses*, 3d ed., 1882) the dogmatic and the historical matter are rather juxtaposed than vitally combined. It is true that he has most usefully applied his vast learning to special historical studies, in relation especially to the progress of the science itself. His treatise *Ueber das Verhältniss der Nationalökonomie zum klassischen Alterthum*, his *Zur Geschichte der Englischen Volkswirtschaftslehre* (Leipsic, 1851-2), and, above all, that marvellous monument of erudition and industry, his *Geschichte der Nationalökonomie in Deutschland* (1874), to which he is said to have devoted fifteen years of study, are among the most valuable extant works of this kind, though the last by its accumulation of detail is unfitted for general study outside of Germany itself. Several interesting and useful monographs are collected in his *Ausichten der Volkswirtschaft vom geschichtlichen Standpunkte* (3d ed., 1878). His systematic treatise, too, above referred to, abounds in historical notices of the rise and development of the several doctrines of the science. But it cannot be alleged that he has done much towards the transformation of political economy which his earliest labours seemed to announce; and Cossa appears to be right in saying that his dogmatic work has not effected any substantial modification of the principles of Hermann and Rau.

The historical method has exhibited its essential features more fully in the hands of the younger generation of scientific economists in Germany, amongst whom may be reckoned Lujo Brentano, Adolf Held, Erwin Nasse, Gustav Schmoller, H. Rösler, Albert Schäffle, Hans von Scheel, Gustav Schönberg, and Adolf Wagner. Besides the general principle of an historical treatment of the science, the leading ideas which have been most strongly insisted on by this school are the following. I. The necessity of accentuating the moral element in economic study. This consideration has been urged with special emphasis by Schmoller in his *Grundfragen* (1875) and by Schäffle in his *Das gesellschaftliche System der menschlichen Wirtschaft* (3d ed., 1873). G. Kries (d. 1858) appears also to have handled the subject well in a review of J. S. Mill. According to the most advanced organs of the school, three principles of organization are at work in practical economy; and, corresponding with these, there are three different systems or spheres of activity. The latter are (1) private economy; (2) the compulsory public economy; (3) the "caritative" sphere. In the first alone personal interest predominates; in the second the general interest of the society; in the third the benevolent impulses. Even in the first, however, the action of private interest cannot be unlimited; not to speak here of the intervention of the public power, the excesses and abuses of the fundamental principle in this department must be checked and controlled by an economic morality, which can never be left out of account in theory any more than in practical applications. In the third region above-named, moral influences are of course supreme. II. The close relation which necessarily exists between economics and jurisprudence. This has been brought out by L. von Stein and H. Rösler, but is most systematically established by Wagner—who is, without doubt, one of the most eminent of living German economists—especially in his *Grundlegung*, now forming part of the *Lehrbuch der politischen Ökonomie* in course of publication by him and Professor Nasse jointly. The doctrine of the *jus naturæ*, on which the physiocrats, as we have seen, reared their economic structure, has lost its hold on belief, and the old *a priori* and absolute conceptions of personal freedom and property have given way along with it. It is seen that the economic position of the individual, instead of depending merely on so-called natural rights or even on his natural powers, is conditioned by the contemporary juristic system, which is itself an historical product. The above-named conceptions, therefore, half economic half juristic, of freedom and property require a fresh examination. It is principally from this point of

view that Wagner approaches economic studies. The point, as he says, on which all turns is the old question of the relation of the individual to the community. Whoever with the older juristic and political philosophy and national economy places the individual in the centre comes necessarily to the untenable results which, in the economic field, the physiocratic and Smithian school of free competition has set up. Wagner on the contrary investigates, before anything else, the conditions of the economic life of the community, and, in subordination to this, determines the sphere of the economic freedom of the individual.

III. A different conception of the functions of the state from that entertained by the school of Smith. The latter school has in general followed the view of Rousseau and Kant that the sole office of the state is the protection of the members of the community from violence and fraud. This doctrine, which was in harmony with those of the *jus naturæ* and the social contract, was temporarily useful for the demolition of the old economic system with its complicated apparatus of fetters and restrictions. But it could not stand against a rational historical criticism, and still less against the growing practical demands of modern civilization. In fact, the abolition of the impolitic and discredited system of European Governments, by bringing to the surface the evils arising from unlimited competition, irresistibly demonstrated the necessity of public action according to new and more enlightened methods. The German historical school recognizes the state as not merely an institution for the maintenance of order, but as the organ of the nation for all ends which cannot be adequately effected by voluntary individual effort. Whenever social aims can be attained only or most advantageously through its action, that action is justified. The cases in which it can properly interfere must be determined separately on their own merits and in relation to the stage of national development. It ought certainly to promote intellectual and æsthetic culture. It ought to enforce provisions for public health and regulations for the proper conduct of production and transport. It ought to protect the weaker members of society, especially women, children, the aged, and the destitute, at least in the absence of family maintenance and guardianship. It ought to secure the labourer against the worst consequences of personal injury not due to his own negligence, to assist through legal recognition and supervision the efforts of the working classes for joint no less than individual self-help, and to guarantee the safety of their earnings, when entrusted to its care.

A special influence which has worked on this more recent group is that of theoretic socialism; we shall see hereafter that socialism as a party organization has also affected their practical politics. With such writers as St. Simon, Fourier, and Prondhon, Lassalle, Marx, Engels, Marlo, and Rodbertus (who, notwithstanding a recent denial, seems rightly described as a socialist) we do not deal in the present sketch (see SOCIALISM); but we must recognize them as having powerfully stimulated the younger German economists (in the strict sense of this last word). They have even modified the scientific conclusions of the latter, especially through criticism of the so-called orthodox system. Schäffle and Wagner may be especially named as having given a large space and a respectful attention to their arguments. In particular, the important consideration, to which we have already referred, that the economic position of the individual depends on the existing legal system, and notably on the existing organization of property, was first insisted on by the socialists. They had also pointed out that the present institutions of society in relation to property, inheritance, contract, and the like are (to use Lassalle's phrase) "historical categories which have changed, and are subject to further change," whilst in the

orthodox economy they are generally assumed as a fixed order of things on the basis of which the individual creates his own position. J. S. Mill called attention to the fact of the distribution of wealth depending, unlike its production, not on natural laws alone, but on the ordinances of society, but it is some of the German economists of the younger historical school who have most strongly emphasized this view. To rectify and complete the conception, however, we must bear in mind that those ordinances themselves are not arbitrarily changeable, but are conditioned by the stage of general social development.

In economic politics these writers have taken up a position between the German free-trade (or, as it is sometimes with questionable propriety called, the Manchester) party and the democratic socialists. The latter invoke the omnipotence of the state to transform radically and immediately the whole economic organization of society in the interest of the proletariat. The free-traders seek to minimize state action for any end except that of maintaining public order, and securing the safety and freedom of the individual. The members of the school of which we are now speaking, when intervening in the discussion of practical questions, have occupied an intermediate standpoint. They are opposed alike to social revolution and to rigid *laissez faire*. Whilst rejecting the socialistic programme, they call for the intervention of the state, in accordance with the theoretic principles already mentioned, for the purpose of mitigating the pressure of the modern industrial system on its weaker members, and extending in greater measure to the working classes the benefits of advancing civilization. Schäffle in his *Capitalismus und Socialismus* (1870; now absorbed into a larger work), Wagner in his *Rede über die sociale Frage* (1871), and Schönberg in his *Arbeitsämter: eine Aufgabe des deutschen Reichs* (1871) advocated this policy in relation to the question of the labourer. These expressions of opinion, with which most of the German professors of political economy sympathized, were violently assailed by the organs of the free-trade party, who found in them "a new form of socialism." Out of this arose a lively controversy; and, the necessity of a closer union and a practical political organization being felt amongst the partisans of the new direction, a congress was held at Eisenach in October 1872, for the consideration of "the social question." It was attended by almost all the professors of economic science in the German universities, by representatives of the several political parties, by leaders of the working men, and by some of the large capitalists. At this meeting the principles above explained were formulated. Those who adopted them obtained from their opponents the appellation of "Katheder-Socialisten," or "socialists of the (professorial) chair," a nickname invented by H. B. Oppenheim, and which those to whom it was applied were not unwilling to accept. Since 1873 this group has been united in the "Verein für Socialpolitik," in which, as the controversy became mitigated, free-traders also have taken part. Within the Verein a division has shown itself. The left wing has favoured a systematic gradual modification of the law of property in such a direction as would tend to the fulfilment of the socialistic aspirations, so far as these are legitimate, whilst the majority advocate reform through state action on the basis of existing jural institutions. Schäffle goes so far as to maintain that the present "capitalistic" régime will be replaced by a socialistic organization; but, like J. S. Mill, he adjourns this change to a more or less remote future, and expects it as the result of a natural development, or process of "social selection;"<sup>1</sup> he repudiates any immediate

<sup>1</sup> This should be remembered by readers of M. Leroy-Beaulieu's recent work on Collectivism (1884), in which he treats Schäffle as the principal theoretic representative of that form of socialism.

or violent revolution, and rejects any system of life which would set up "abstract equality" against the claims of individual service and merit.

The further the investigations of the German historical school have been carried, in the several lines of inquiry it has opened, the more clearly it has come to light that the one thing needful is not merely a reform of political economy, but its fusion in a complete science of society. This is the view long since insisted on by Auguste Comte; and its justness is daily becoming more apparent. The best economists of Germany now tend strongly in this direction. Schäffle, who is largely under the influence of Comte and Herbert Spencer, has actually attempted the enterprise of widening economic into social studies. In his most important work, which had been prepared by previous publications, *Bau und Leben des sozialen Körpers* (1875-78; new ed., 1881), he proposes to give a comprehensive plan of an anatomy, physiology, and psychology of human society. He considers social processes as analogous to those of organic bodies; and, sound and suggestive as the idea of this analogy, already used by Comte, undoubtedly is, he carries it, perhaps, to an undue degree of detail and elaboration. The same conception is adopted by P. von Lilienfeld in his *Gedanken über die Sozialwissenschaft der Zukunft* (1873-79). A tendency to the fusion of economic science in sociology is also found in Adolph Samter's *Sozial-lehre* (though the economic aspect of society is there specially studied) and in Schmoller's treatise *Ueber einige Grundfragen des Rechts und der Volkswirtschaftslehre*; and the necessity of such a transformation is energetically asserted by H. von Scheel in the preface to his German version (1879) of an English tract *On the present Position and Prospects of Political Economy*.

The name "Realistic," which has sometimes been given to the historical school, especially in its more recent form, appears to be injudiciously chosen. It is intended to mark the contrast with the "abstract" complexion of the orthodox economics. But the error of these economics lies, not in the use, but in the abuse of abstraction. All science implies abstraction, seeking, as it does, for unity in variety; the question in every branch is as to the right constitution of the abstract theory in relation to the concrete facts. Nor is the new school quite correctly distinguished as "inductive." Deduction doubtless unduly preponderates in the investigations of the older economists; but it must be remembered that it is a legitimate process, when it sets out, not from *a priori* assumptions, but from proved generalizations. And the appropriate method of economics, as of all sociology, is not so much induction as the specialized form of induction known as comparison, especially the comparative study of "social series" (to use Mill's phrase), which is properly designated as the "historical" method. If the denominations here criticized were allowed to prevail, there would be a danger of the school assuming an unscientific character. It might occupy itself too exclusively with statistical inquiry, and forget in the detailed examination of particular provinces of economic life the necessity of large philosophic ideas and of a systematic co-ordination of principles. So long as economics remain a separate branch of study, and until they are absorbed into sociology, the thinkers who follow the new direction will do wisely in retaining their original designation of the historical school.

The members of the historical school have produced many valuable works besides those which there has been occasion to mention above. Ample notices of their contributions to the several branches of the science (including its applications) will be found dispersed through Wagner and Nasse's *Lehrbuch* and the comprehensive *Handbuch* edited by Schönberg. The following list, which does not pretend to approach to completeness, is given for the purpose of directing the student to a certain number of books which ought

not to be overlooked in the study of the subjects to which they respectively refer:—

Kries, *Die Eisenbahnen und ihre Wirkungen* (1853), *Der Telegraph* (1857), *Geld und Credit* (1873-76-79); Rösler, *Zur Kritik der Lehre vom Arbeitslohn*, 1861; Schmoller, *Zur Geschichte der deutschen Kleinrenten im 19. Jahrh.*, 1870; Schäffle, *Theorie der ausschliessenden Absatzverhältnisse* (1867), *Quintessenz des Sozialismus* (8th ed., 1878), *Grundzüge der Steuerpolitik* (1880); Nasse, *Mittelalterliche Feldgemeinschaft in England*, 1869; Drentano, *On the History and Development of Guilds*, prefixed to Toulmin Smith's *English Guilds* (1870), *Die Arbeitergilden der Gegenwart* (1871-72), *Das Recht* (1877), *Die Arbeitsversicherung gem.* (1879), *Der Arbeitsversicherungszwang* (1881), *sein* (born 1814, accidentally drowned in the Lake of Thun 1850), *Die Einkommensteuer* (1872), *Die deutsche Arbeiterpresse der Gegenwart* (1873), *Sozialismus, Sozialdemokratie, und Sozialpolitik* (1878), *Grundriss für Vorlesungen über National-ökonomie* (2d ed., 1878); *Zwei Bücher zur sozialen Geschichte Englands* (posthumously published, 1891); Von Scheel (born 1839), *Die Theorie der sozialen Frage* (1871), *Unsere social-politischen Parteien* (1875). To these may be added L. von Stein, *Die Vertheilungslehre* (1876-79), *Lehrbuch der Finanzwissenschaft* (4th ed., 1878). E. Dühring is the ablest of the few German followers of Carey; we shall mention his history hereafter. To the Russian-German school belongs the work of T. von Bernhardi, which is written from the historical point of view, *Versuch einer Kritik der Gründe welche für grosses und kleines Grundeigenthum angeführt werden*, 1818. The free-trade school of Germany is recognized as having rendered great practical services in that country, especially by its systematic warfare against antiquated privileges and restrictions. Cobden has furnished the model of its political action, whilst, on the side of theory, it is founded chiefly on Say and Bastiat. The members of this school whose names have been most frequently heard by the English public are those of J. Prince Smith, who may be regarded as its head; H. von Treitschke, author of *Der Socialismus und seine Götter*, 1876 (directed against the Kathedol-Sozialisten); V. Bismarck, who has advocated the participation of workmen in profits (*Die Gewerbetheiligung*, 1878); and J. H. Schultz-Delitzsch, well known as the founder of the German popular banks, and a strenuous supporter of the system of "co-operation." The socialist writers, as has been already mentioned, are not included in the present historical survey, nor do we in general notice writings of the economists (properly so called) having relation to the history of socialism or the controversy with it.

The movement which created this school in Germany, with the developments which have grown out of it, have without doubt given to that country at the present time the primacy in economic studies. German influence has been felt in the modification of opinion in other countries—most strongly, perhaps, in Italy, and least so in France. In England it has been steadily making way, though retarded by the insular indifference to the currents of foreign thought which has eminently marked our dominant school. Alongside of the influence thus exerted, a general distaste for the "orthodox" system has been spontaneously growing, partly from a suspicion that its method was unsound, and partly from a profound dissatisfaction with the practice it inspired, and the detected hollowness of the "Manchester" policy of mere *laissez faire*. Hence everywhere a mode of thinking and a species of research have shown themselves, and come into favour, which are in harmony with the systematic conceptions of the historical economists. Thus a dualism has established itself in the economic world, a younger school advancing towards predominance, whilst the old school still defends its position, though its adherents tend more and more to modify their attitude and to admit the value of the new lights.

*Italy.*—It is to be regretted that very little is known in England of the writings of the recent Italian economists. Luigi Cossa's *Guida*, which was translated at the suggestion of Jevons, has given us some notion of the character and importance of their labours. The urgency of questions of finance in Italy since its political renaissance has turned their researches for the most part into practical channels, and they have produced numerous monographs on statistical and administrative questions. But they have also dealt ably with the general doctrines of the science. Cossa pronounces Angelo Messedaglia (b. 1820), professor at Padua, to be the foremost of contemporary Italian economists; he has written on public loans (1850) and on population (1858), and is regarded as a master of the subjects of money and credit. His pupil Fedele Lampertico (b. 1833) is author of many writings, among which the most systematic and complete is his *Economia dei popoli e degli stati* (1874-1880). Marco Minghetti, distinguished as a minister, is author, besides other writings, of *Economia pubblica e le sue attinenze colla morale e col diritto* (1859). Luigi Luzzati, also known as an able administrator, has by several publications sought to prepare the way for reforms. The Sicilians Vito Cus-

mano and Giuseppe Ricca Salerno have produced excellent works:—the former on the history of political economy in the Middle Ages (1876), and the economic schools of Germany in their relation to the social question (1875); the latter on the theories of capital, wages, and public loans (1877-8-9). Cossa, to whom we are indebted for most of these particulars, is himself author of several works which have established for him a high reputation, as his *Scienza delle Finanze* (1875; 3d ed., 1882), and his *Primi Elementi di Economia Politica* (1875; 4th ed., 1878), which latter has been translated into several European languages.

Of greater interest than such an imperfect catalogue of writers is the fact of the appearance in Italy of the economic dualism to which we have referred as characterizing our time. There also the two schools—the old or so-called orthodox and the new or historical—with their respective modified forms, are found face to face. Cossa tells us that the instructors of the younger economists in northern Italy were publicly denounced in 1874 as Germanists, socialists, and corrupters of the Italian youth. In reply to this charge Luzzati, Lampertico, and Scialoja convened in Milan the first congress of economists (1875) with the object of proclaiming their resistance to the idea which was sought to be imposed on them "that the science was born and died with Adam Smith and his commentators." M. de Lavéleye's interesting *Lettres d'Italie* (1878-79) throw light on the state of economic studies in that country in still more recent years. Minghetti, presiding at the banquet at which M. de Lavéleye was entertained by his Italian brethren, spoke of the "two tendencies" which had manifested themselves, and implied his own inclination to the new view. Carlo Ferrari, a pupil of Wagner, follows the same direction. Formal expositions and defenses of the historical method have been produced by Schiattarella (*Del metodo in Economia Sociale*, 1875) and Cognetti de Martiis (*Della attinenza tra l'Economia Sociale e la Storia*, 1895). A large measure of acceptance has also been given to the historical method in learned and judicious monographs by Ricca Salerno (see especially his essay *Del metodo in Econ. Pol.*, 1878). Luzzati and Forti for some time edited a periodical, the *Giornale degli Economisti*, which was the organ of the new school, but which, we gather from Cossa, has ceased to appear. Cossa himself, whilst refusing his adhesion to this school on the ground that it reduces political economy to a mere narrative of facts,—an observation which, we must be permitted to say, betrays an entire misconception of its true principles,—admits that it has been most useful in several ways, and especially as having given the signal for a salutary, though, as he thinks, an excessive, reaction against the doctrinaire exaggerations of the older theorists.

*France.*—In France the historical school has not made so strong an impression,—partly, no doubt, because the extreme doctrines of the Ricardian system never obtained much hold there. It was by his recognition of its freedom from those exaggerations that Jevons was led to declare that "the truth is with the French school," whilst he pronounced our English economists to have been "living in a fool's paradise." National prejudice may also have contributed to the result referred to, the ordinary Frenchman being at present disposed to ask whether any good thing can come out of Germany. But, as we have shown, the philosophic doctrines on which the whole proceeding of the historical school is founded were first enunciated by a great French thinker, to whose splendid services most of his fellow-countrymen are singularly dead. Perhaps another determining cause is to be looked for in official influences, which in France, by their action on the higher education, impede the free movement of independent conviction, as was seen notably in the temporary *écart* they

gave on the wider philosophic stage to the shallow eclecticism of Cousin. The tendency to the historical point of view has appeared in France, as elsewhere; but it has shown itself not so much in modifying general doctrine as in leading to a more careful study of the economic opinions and institutions of the past.

Much useful work has been done by Frenchmen (with whom Belgians may here be associated) in the history of political economy, regarded either as a body of theory or as a system—or series of systems—of policy. Blanqui's history (1837-38) is not, indeed, entitled to a very high rank, but it is as serviceable as a first general draught. That of V... (1839) was also interesting and useful, as... view of the development and tendencies of the science. C. Perin's *Les doctrines économiques depuis un siècle* (1880) is written from the same point of view. A number of valuable monographs on particular states men or thinkers has also been produced by... Bathé, on Turgot (*Turgot*, 1861); of Pierre Clément on Colbert (*Histoire de Colbert et de son Administration*, 2d ed., 1875), of H. Baudrillart on Bodin (*J. Bodin et ses Temps; Tableau des Théories politiques et des Idées économiques au 16<sup>e</sup> siècle*, 1853); of L. de Lavéleye on the physiocrats (*Les Économistes Français du 18<sup>e</sup> siècle*, 1870). Works, too, of real importance have been produced on particular aspects of the industrial development, as those of L. de Lavéleye on the rural economy of France (1857), and of England, Scotland, and Ireland (1854). The treatise of Emile de Laveleye, *De la Propriété et de ses formes*, Laveleye's (1874; Eng. trans. by G. R. Marriott, 1878), is especially worthy of notice, not merely for its array of facts respecting the early forms of property, but because it co-operates strongly with the tendency of the new school to regard each stage of economic life from the relative point of view, as resulting from an historic past, harmonizing with the entire body of contemporary social conditions, and bearing in its bosom the germs of a future, predetermined in its essential character, though modifiable in its secondary dispositions.

M. de Lavéleye has done much to call attention to the general principles of the historical school, acting in this way most usefully as an interpreter between Germany and France. But he appears in his most recent manifesto (*Les Lois naturelles et l'école de l'École de Politique*, 1883) to separate himself from the best members of that school, and to fall into positive error, when he refuses to recognize the character of a true science (or department of science) as distinguished from an art, and denies the existence of economic laws or tendencies independent of individual wills. Such a denial seems to involve that of social laws generally, which is a singularly retrograde attitude for a thinker of our time to take up, and one which cannot be excused since the appearance of the *Philosophie Positive*. The use of the metaphysical phrase "necessary laws" obscures the question; it suffices to speak of laws which do in fact prevail. M. de Lavéleye relies on morals as supplying a parallel case, where we deal, not with natural laws, but with "imperative prescriptions," as if the prescriptions did not imply, as their basis, observed coexistences and sequences, and as if there were no such thing as moral evolution. He seems to be as far from the right point of view in one direction as his opponents of the old school in another. All that his arguments have really any tendency to prove is the proposition, undoubtedly a true one, that economic facts cannot be explained by a theory which leaves out of account the other social aspects, and therefore that our studies and expositions of economic phenomena must be kept in close relation with the conclusions of the larger science of society.

We cannot do more than notice in a general way some of the expository treatises of which there has been an almost continuous series from the time of Say downwards, or indeed from the date of Germain Garnier's *Abregé des Principes de l'Économie Politique* (1796). That of Destutt de Tracy forms a portion of his *Éléments d'Idéologie* (1823). Dror brought out especially the relations of economics to morals and of wealth to human happiness (*Économie Politique*, 1829). Pellegrino Rossi, an Italian, formed, however, as an economist by studies in Switzerland, professing the science in Paris, and writing in French (*Cours d'Économie Politique*, 1835-54), gave in classic form an exposition of the doctrines of Say, Malthus, and Ricardo. Michel Clapham (1808-1879), especially known in England by his tract, translated by Cobden, on the fall in the value of gold (*La Baisse d'Or*, 1838), gives in his *Cours d'Économie Politique* (1845-50) particularly valuable matter on the most recent industrial phenomena, and on money and the production of the precious metals. Henri Baudrillart, author of *Les Rapports de la Morale et de l'Économie Politique* (1860, 2d ed., 1883), and of *Histoire du Lait* (1878), published in 1857 a *Manuel d'Économie Politique* (3d ed., 1872), which Cossa calls an "admirable compendium." Joseph Garnier (*Traité de l'Économie Politique*, 1860, 8th ed., 1880) in some respects follows Dunoyer. J. G. Courcelle Senelle, the translator of J. S. Mill, whom Prof. F. A. Waller calls "perhaps the ablest economist writing in the French language since J. B.

Say," besides a *Traité théorique et pratique des opérations de Banque* and *Théorie des Entreprises Industrielles* (1856), wrote a *Traité de l'Economie Politique* (1858-59), which is held in much esteem. Finally, the Genevese, Antoine Elise Cherbuliez (d. 1869) was author of what Cossa pronounces to be the best treatise on the science in the French language (*Précis de la Science Économique*, 1862). L. Walras, in *Éléments d'Economie Politique pure* (1874-77), and *Théorie Mathématique de la Richesse Sociale* (1893), has followed the example of Cournot in attempting a mathematical treatment of the subject.

England.—Sacrificing the strict chronological order of the history of economics to deeper considerations, we have already spoken of Cairnes, describing him as the last original English writer who was an adherent of the old school pure and simple. Both in method and doctrine he was essentially Ricardian; though professing and really feeling profound respect for Mill, he was disposed to go behind him and attach himself rather to their common master. Mr Sidgwick is doubtless right in believing that his *Leading Principles* did much to shake "the unique prestige which Mill's exposition had enjoyed for nearly half a generation," and in this, as in some other ways, Cairnes may have been a dissolving force, and tended towards radical change; but, if he exercised this influence, he did so unconsciously and involuntarily. Many influences had, however, for some time been silently sapping the foundations of the old system. The students of Comte had seen that its method was an erroneous one. The elevated moral teaching of Carlyle had disgusted the best minds with the low maxims of the Manchester school. Ruskin had not merely protested against the egoistic spirit of the prevalent doctrine, but had pointed to some of its real weaknesses as a scientific theory.<sup>1</sup> It began to be felt, and even its warmest partisans sometimes admitted, that it had done all the work, mainly a destructive one, of which it was capable. Cairnes himself declared that, whilst most educated people believed it doomed to sterility for the future, some energetic minds thought it likely to be a positive obstruction in the way of useful reform. Miss Martineau, who had in earlier life been a thorough Ricardian, came to think that political economy, as it had been elaborated by her contemporaries, was, strictly speaking, no science at all, and must undergo such essential change that future generations would owe little to it beyond the establishment of the existence of general laws in one department of human affairs. The instinctive repugnance of the working classes had continued, in spite of the efforts of their superiors to recommend its lessons to them—efforts which were perhaps not unfrequently dictated rather by class interest than by public spirit. All the symptoms boded impending change, but they were visible rather in general literature and in the atmosphere of social opinion than within the economic circle. But when it became known that a great movement had taken place, especially in Germany, on new and more hopeful lines, the English economists themselves began to recognize the necessity of a reform and even to further its advent. The principal agencies of this kind, in marshalling the way to a renovation of the science, have been those of Bagehot, Leslie, and Jevons,—the first limiting the sphere of the dominant system, while seeking to conserve it within narrower bounds; the second directly assailing it and setting up the new method as the rival and destined successor of the old; and the third acknowledging the collapse of the hitherto reigning dynasty, proclaiming the necessity of an altered régime, and admitting the younger claimant as joint possessor in the future. Thus, in England too, the dualism which exists on the Continent has been established, and there is reason to

expect that here more speedily and decisively than in France or Italy the historical school will displace its antagonist. It is certainly in England next after Germany that the preaching of the new views has been most vigorously and effectively begun.

Walter Bagehot (1826-1877) was author of an excellent Bagehot work on the English money market and the circumstances which have determined its peculiar character (*Lombard Street*, 1873; 7th ed., 1878), and of several monographs on particular monetary questions, which his practical experience, combined with his scientific habits of thought, eminently fitted him to handle. On the general principles of economics he wrote some highly important essays collected in *Economic Studies* (edited by R. H. Hutton, 1880), the object of which was to show that the traditional system of political economy—the system of Ricardo and J. S. Mill—rested on certain fundamental assumptions, which, instead of being universally true in fact, were only realized within very narrow limits of time and space. Instead of being applicable to all states of society, it holds only in relation to those "in which commerce has largely developed, and where it has taken the form of development, or something like the form, which it has taken in England." It is "the science of business such as business is in large and trading communities—an analysis of the great commerce by which England has become rich." But more than this it is not; it will not explain the economic life of earlier times, nor even of other communities in our own time; and for the latter reason it has remained insular; it has never been fully accepted in other countries as it has been at home. It is, in fact, a sort of ready reckoner, enabling us to calculate roughly what will happen under given conditions in Lombard Street, on the Stock Exchange, and in the great markets of the world. It is a "convenient series of deductions from assumed axioms which are never quite true, which in many times and countries would be utterly untrue, but which are sufficiently near to the principal conditions of the modern English world to make it useful to consider them by themselves."

Mill and Cairnes had already shown that the science they taught was a hypothetical one, in the sense that it dealt not with real but with imaginary men—"economic men" who were conceived as simply "money-making animals." But Bagehot went further: he showed what those writers, though they may have indicated, had not clearly brought out,<sup>2</sup> that the world in which these men were supposed to act is also "a very limited and peculiar world." What marks off this special world, he tells us, is the promptness of transfer of capital and labour from one employment to another, as determined by differences in the remuneration of those several employments—a promptness, about the actual existence of which in the contemporary English world he fluctuates a good deal, but which on the whole he recognizes as substantially realized.

Bagehot described himself as "the last man of the ante-Mill period," having learned his economics from Ricardo; and the latter writer he appears to have to the end greatly over-estimated. But he lived long enough to gain some knowledge of the historical method, and with it he had "no quarrel, but rather much sympathy." "Rightly conceived," he said, "it is no rival to the abstract method rightly conceived." We will not stop to criticize a second time the term "abstract method" here applied to that of the old school, or to insist on the truth that all science is necessarily abstract, the only question that can arise being as to the just degree of abstraction, or, in general, as to the right constitution of the relation between the abstract and

<sup>1</sup> The remarkable book *Money and Morals*, by John Lalor, 1852, was written partly under the influence of Carlyle. There is a good monograph entitled *John Ruskin, Economist*, by P. Geddes, 1884.

<sup>2</sup> Jones, whose writings were apparently unknown to Bagehot, had, as we have seen, in some degree anticipated him in this exposition.

the concrete. It is more apposite to remark that Bagehot's view of the reconciliation of the two methods is quite different from that of most "orthodox" economists. They commonly treat the historical method with a sort of patronizing toleration as affording useful exemplifications or illustrations of their theorems. But, according to him, the two methods are applicable in quite different fields. For what he calls the "abstract" method he reserves the narrow, but most immediately interesting, province of modern advanced industrial life, and hands over to the historical the economic phenomena of all the human past and all the rest of the human present. He himself exhibits much capacity for such historical research, and in particular has thrown real light on the less-noticed economic and social effects of the institution of money, and on the creation of capital in the earlier stages of society. But his principal efficacy has been in reducing, by the considerations we have mentioned, still further than his predecessors had done, our conceptions of the work which the *a priori* method can do. He in fact dispelled the idea that it can ever supply the branch of general sociology which deals with wealth. As to the relations of economics to the other sides of sociology, he holds that the "abstract" science rightly ignores them. It does not consider the differences of human wants, or the social results of their several gratifications, except so far as these affect the production of wealth. In its view "a pot of beer and a picture—a book of religion and a pack of cards—are equally worthy of regard." It therefore leaves the ground open for a science which will, on the one hand, study wealth as a social fact in all its successive forms and phases, and, on the other, will regard it in its true light as an instrument for the conservation and evolution—moral as well as material—of human societies.

Though it will involve a slight digression, it is desirable here to notice a further attenuation of the functions of the deductive method, which is well pointed out in Mr Sidgwick's recent remarkable work on political economy. He observes that, whilst J. S. Mill declares that the method *a priori* is the true method of the science, and that "it has been so understood and taught by all its most distinguished teachers," he yet himself in the treatment of production followed an inductive method (or at least one essentially different from the deductive), obtaining his results by "merely analysing and systematizing our common empirical knowledge of the facts of industry." To explain this characteristic inconsistency, Mr Sidgwick suggests that Mill, in making his general statement as to method, had in contemplation only the statics of distribution and exchange. And in this latter field Mr Sidgwick holds that the *a priori* method, if it be pursued with caution, if the simplified premises be well devised and the conclusions "modified by a rough conjectural allowance" for the elements omitted in the premises, is not, for the case of a developed industrial society, "essentially false or misleading." Its conclusions are hypothetically valid, though "its utility as a means of interpreting and explaining concrete facts depends on its being used with as full a knowledge as possible of the results of observation and induction." We do not think this statement need be objected to, though we should prefer to regard deduction from hypothesis as a useful occasional logical artifice, and, as such, perfectly legitimate in this as in other fields of inquiry, rather than as the main form of method in any department of economics. Mr Sidgwick, by his limitation of deduction in distributional questions to "a state of things taken as the type to which civilized society generally approximates," seems to agree with Bagehot that for times and places which do not correspond to this type the historical method must be used—a method which, be it observed, does not exclude, but positively implies, "reflective analysis" of the facts, and their interpretation from "the motives of human agents" as well as from other determining conditions. In the dynamical study of wealth—of the changes in its distribution no less than its production—Mr Sidgwick admits that the method *a priori* "can occupy but a very subordinate place." We should say that here also, though to a less extent, as a logical artifice it may sometimes be useful, though the hypotheses assumed ought not to be the same that are adapted to a mature industrial stage. But the essential organ must be the historical method, studying comparatively the different phases of social evolution.

Connected with the theory of modern industry is one

subject which Bagehot treated, though only in an incidental way, much more satisfactorily than his predecessors,—namely, the function of the entrepreneur, who in Mill and Cairnes is scarcely recognized except as the owner of capital. It is quite singular how little, in the *Leading Principles* of the latter, his active co-operation is taken into account. Bagehot objects to the phrase "wages of superintendence," commonly used to express his "reward," as suggesting altogether erroneous ideas of the nature of his work, and well describes the large and varied range of his activity and usefulness, and the rare combination of gifts and acquirements which go to make up the perfection of his equipment. It can scarcely be doubted that a foregone conclusion in favour of the system of (so-called) co-operation has sometimes led economists to keep these important considerations in the background. They have been brought into due prominence of late in the treatises of Profs. Marshall and F. A. Walker, who, however, have scarcely made clear, and certainly have not justified, the principle on which the amount of the remuneration of the entrepreneur is determined.

We have seen that Jones had in his dogmatic teaching anticipated in some degree the attitude of the new school; important works had also been produced, notably by Thomas Tooke and William Newmarch (*History of Prices, 1838-1857*), and by James E. Thorold Rogers (*History of Agriculture and Prices in England, 1866-82*), on the course of English economic history. But the first systematic statement by an English writer of the philosophic foundation of the historical method, as the appropriate organ of economic research, is to be found in an essay by T. E. Cliffe Leslie (printed in the Dublin University periodical, *Hermathena*, 1876; since included in his *Essays Moral and Political*, 1879). This essay was the most important publication on the logical aspect of economic science which had appeared since Mill's essay in his *Unsettled Questions*. Though Cairnes had expanded and illustrated the views of Mill, he had really added little to their substance. Leslie takes up a position directly opposed to theirs. He criticizes with much force and verve the principles and practice of the "orthodox" school. Those who are acquainted with what has been written on this subject by Knies and other Germans will appreciate the freshness and originality of Leslie's treatment. He points out the loose and vague character of the principle to which the classical economists profess to trace back all the phenomena with which they deal—namely, the "desire of wealth." This phrase really stands for a variety of wants, desires, and sentiments, widely different in their nature and economic effects, and undergoing important changes (as, indeed, the component elements of wealth itself also do) in the several successive stages of the social movement. The truth is that there are many different economic motors, altruistic as well as egoistic; and they cannot all be lumped together by such a coarse generalization. The *a priori* and purely deductive method cannot yield an explanation of the causes which regulate either the nature or the amount of wealth, nor of the varieties of distribution in different social systems, as, for example, in those of France and England. "The whole economy of every nation is the result of a long evolution in which there has been both continuity and change, and of which the economical side is only a particular aspect. And the laws of which it is the result must be sought in history and the general laws of society and social evolution." The intellectual, moral, legal, political, and economic sides of social progress are indissolubly connected. Thus, juridical facts relating to property, occupation, and trade, thrown up by the social movement, are also economic facts. And, more generally, "the economic condition of English" or any

other "society at this day is the outcome of the entire movement which has evolved the political constitution, the structure of the family, the forms of religion, the learned professions, the arts and sciences, the state of agriculture, manufactures, and commerce." To understand existing economic relations we must trace their historical evolution; and "the philosophical method of political economy must be one which expounds that evolution." This essay was the most distinct challenge ever addressed to the ideas of the old school on method, and, though its conclusions have been protested against, the arguments on which they are founded have never been answered.

With respect to the dogmatic generalizations of the "orthodox" economics, Leslie thought some of them were false, and all of them required careful limitation. Early in his career he had shown the hollowness of the wage-fund theory, though he was not the first to repudiate it.<sup>1</sup> The doctrine of an average rate of wages and an average rate of profits he rejected except under the restrictions stated by Adam Smith, which imply a "small and stationary world of trade." He thought the glib assumption of an average rate of wages, as well as of a wage-fund, had done much harm "by hiding the real rates of wages, the real causes which govern them, and the real sources from which wages proceed." The facts, which he laboriously collected, he found to be everywhere against the theory. In every country there is really "a great number of rates; and the real problem is, What are the causes which produce these different rates?" As to profits, he denies that there are any means of knowing the gains and prospects of all the investments of capital, and declares it to be a mere fiction that any capitalist surveys the whole field. Bagehot, as we saw, gave up the doctrine of a national level of wages and profits except in the peculiar case of an industrial society of the contemporary English type; Leslie denies it even for such a society. With this doctrine, that of cost of production as determining price collapses, and the principle emerges that it is not cost of production, but demand and supply, on which domestic, no less than international, values depend,—though this formula will require much interpretation before it can be used safely and with advantage. Thus Leslie extends to the whole of the national industry the partial negation of the older dogma introduced by Cairnes through the idea of non-competing groups. He does not, of course, dispute the real operation of cost of production on price in the limited area within which rates of profit and wages are determinate and known; but he maintains that its action on the large scale is too remote and uncertain to justify our treating it as regulator of price. Now, if this be so, the entire edifice which Ricardo reared on the basis of the identity of cost of production and price, with its apparent but unreal simplicity, symmetry, and completeness, disappears; and the ground is cleared for the new structure which must take its place. Leslie predicts that, if political economy, under that name, does not bend itself to the task of rearing such a structure, the office will speedily be taken out of its hands by sociology.

Leslie was a successful student of several special economic subjects—of agricultural economy, of taxation, of the distribution of the precious metals and the history of prices, and, as has been indicated, of the movements of wages. But it is in relation to the method and fundamental doctrines of the science that he did the most

important, because the most opportune and needful work. And, though his course was closed too early for the interests of knowledge, and much of what he produced was merely occasional and fragmentary, his services will be found to have been greater than those of many who have left behind them more systematic, elaborate, and pretentious writings.

One of the most original of recent English writers on Jevons political economy was W. Stanley Jevons (1835-1882). The combination which he presented of a predilection and aptitude for exact statistical inquiry with sagacity and ingenuity in the interpretation of the results was such as might remind us of Petty. He tended strongly to bring economics into close relation with physical science. He made a marked impression on the public mind by his attempt to take stock of our resources in the article of coal. His idea of a relation between the recurrences of commercial crises and the period of the sun-spots gave evidence of a fertile and bold scientific imagination, though he cannot be said to have succeeded in establishing such a relation. He was author of an excellent treatise on *Money and the Mechanism of Exchange* (1875), and of various essays on currency and finance, which have been collected since his death, and contain vigorous discussions on subjects of this nature, as on bimetalism (with a decided tendency in favour of the single gold standard), and several valuable suggestions, as with respect to the most perfect system of currency, domestic and international, and in particular the extension of the paper currency in England to smaller amounts. He proposed in other writings (collected in *Methods of Social Reform*, 1883) a variety of measures, only partly economic in their character, directed especially to the elevation of the working classes, one of the most important being in relation to the conditions of the labour of married women in factories. This was one of several instances in which he repudiated the *laissez faire* principle, which indeed, in his book on *The State in Relation to Labour* (1882), he refuted in the clearest and most convincing way, without changing the position he had always maintained as an advocate of free trade. Towards the end of his career, which was prematurely terminated, he was more and more throwing off "the incubus of metaphysical ideas and expressions" which still impeded the recognition or confused the appreciation of social facts. He was, in his own words, ever more distinctly coming to the conclusion "that the only hope of attaining a true system of economics is to fling aside, once and for ever, the mazy and preposterous assumptions of the Ricardian school." With respect to method, though he declares it to be his aim to "investigate inductively the intricate phenomena of trade and industry," his views had not perhaps assumed a definitive shape. The editor of some of his remains declines to undertake the determination of his exact position with respect to the historical school. The fullest indications we possess on that subject are to be found in a lecture of 1876, *On the Future of Political Economy*. He saw the importance and necessity in economics of historical investigation, a line of study which he himself was led by native bent to prosecute in some directions. But he scarcely apprehended the full meaning of what is called the historical method, which he erroneously contrasted with the "theoretical," and apparently supposed to be concerned with verifying and illustrating certain abstract doctrines resting on independent bases. Hence, whilst he declared himself in favour of "thorough reform and reconstruction," he sought to preserve the *a priori* mode of proceeding alongside of, and concurrently with, the historical. Political economy, in fact, he thought was breaking up and falling into several, probably into many, different branches of inquiry, prominent amongst which would be the "theory" as it

<sup>1</sup> That service was due to F. D. Laing (*Refutation of the Wage-Fund Theory of Modern Political Econ.*, 4, 1866). Leslie's treatment of the subject was contained in an article of *Fraser's Magazine* for July 1868, reprinted as an appendix to his *Land-Systems and Industrial Economy of Ireland, England, and Continental Countries*, 1870.

had descended from his best predecessors, especially those of the French school, whilst another would be the "historical study," as it was followed in England by Jones, Rogers, and others, and as it had been proclaimed in general principle by his contemporary Cliffe Leslie. This was one of those eclectic views which have no permanent validity, but are useful in facilitating a transition. The two methods will doubtless for a time coexist, but the historical will inevitably supplant its rival. What Jevons meant as the "theory" he wished to treat by mathematical methods (see his *Theory of Political Economy*, 1871; 2nd ed., 1879). This project had, as we have seen, been entertained and partially carried into effect by others before him, though he unduly multiplies the number of such earlier essays when, for example, he mentions Ricardo and J. S. Mill as writing mathematically because they sometimes illustrated the meaning of their propositions by dealing with definite arithmetical quantities. Such illustrations, of which a specimen is supplied by Mill's treatment of the subject of international trade, have really nothing to do with the use of mathematics as an instrument for economic research, or even for the co-ordination of economic truths. We have already, in speaking of Cournot, explained why, as it seems to us, the application of mathematics in the higher sense to economics must necessarily fail, and we do not think that it succeeded in Jevons's hands. His conception of "final utility" is ingenious, but we cannot regard it as either "positive" or fruitful. He offers as a valuable result of mathematical investigation the theorem that in every case of exchange the quantity of each of the articles concerned multiplied by its utility is the same. But what is the unit of utility? If we cannot look for something more tangible—not to say more serviceable—than this, there is not much encouragement to pursue such researches, which will in fact never be anything more than academic playthings, and which involve the very real evil of restoring the metaphysical entities previously discarded. The reputation of Jevons as an acute and vigorous thinker, inspired with noble popular sympathies, is sufficiently established. But the attempt to represent him, in spite of himself, as a follower and continuator of Ricardo, and as one of the principal authors of the development of economic theory (meaning by "theory" the old *a priori* doctrine) can only lower him in estimation by placing his services on grounds which will not bear criticism. His name will survive in connexion, not with new theoretical constructions, but with his treatment of practical problems, his fresh and lively expositions, and, as we have shown, his energetic tendency to a renovation of economic method.

Arnold Toynbee (1852-1883), who left behind him a beautiful memory, filled as he was with the love of truth and an ardent and active zeal for the public good, was author of some fragmentary or unfinished pieces, which yet well deserve attention both for their intrinsic merit and as indicating the present drift of all the highest natures, especially amongst our younger men, in the treatment of economic questions. He had a belief in the organizing power of democracy which it is not easy to share, and some strange ideas due to youthful enthusiasm, such as, for example, that Mazzini is "the true teacher of our age;" and he fluctuates considerably in his opinion of the Ricardian political economy, in one place declaring it to be a detected "intellectual imposture," whilst elsewhere, apparently under the influence of Bagehot, he speaks of it as having been in recent times "only corrected, re-stated, and put into the proper relation to the science of life," meaning apparently, by this last, general sociology. He saw, however, that our great help in the future must come, as much had already come, from the historical method, to which in his own researches he gave preponderant weight. Its true

character, too, he understood better than many even of those who have commended it; for he perceived that it not only explains the action of special local or temporary conditions on economic phenomena, but seeks by comparing the stages of social development in different countries and times to "discover laws of universal application." If, as we are told, there exists at Oxford a rising group of men who occupy a position in regard to economic thought substantially identical with that of Toynbee, the fact is one of good omen for the future of the science.

It is no part of our plan to pass judgment on the works of contemporary English authors,—a judgment which could not in general be final, and which would be subject to the imputation of bias in a greater degree than estimates of living writers in foreign countries. But, for the information of the student, some opinions may be expressed which scarcely any competent person would dispute. The best brief exposition of political economy, substantially in accordance with Mill's treatise, is to be found in Fawcett's *Manual* (6th ed., 1884). But those who admit in part the claims of the new school will prefer Mr and Mrs Marshall's *Economics of Industry* (2d ed., 1881). Better, in some respects, than either is the *Political Economy* of the American professor, Francis A. Walker (1883), whose special treatises on *Money* and on the *Wages Question* may also be recommended. Other meritorious works are J. E. T. Rogers's *Manual of Political Economy*, 1870; John Macdonnell's *Survey of Political Economy*, 1871; and John L. Shadwell's *System of Political Economy*, 1877. Prof. W. E. Hearn's *Philology* (1864) contains one of the ablest extant treatments of the subject of production. Mr Goschen's is the best work on the foreign exchanges (10th ed., 1879). Mr Macleod, though his general economic scheme has met with no acceptance, is recognized as supplying much that is useful on the subject of banking. Prof. Rogers's *Six Centuries of Work and Wages* (1884) is the most trustworthy book on the economic history of England during the period with which he deals. W. Cunningham's *Growth of English Industry and Commerce*, 1882, is instructive on the mercantile system. Dr W. Neilson Hancock has shown in a multitude of papers a most extensive and accurate knowledge of the social economy of Ireland.

On American political economy the reader will consult with advantage an article in the *Fortnightly Review* for September, 1880, by Cliffe Leslie, which was written after the publication of his collected essays. We can only mention some of the best-known works (besides those of F. A. Walker) produced in the United States. Amongst them are E. Peshine Smith's *Manual of Political Economy*, 1853; Francis Bowen's *American Political Economy*, 1870; Amasa Walker's *Science of Wealth*, 1867; A. L. Perry's *Elements of Political Economy*, 1866 (the two former writers are protectionist, the two latter free-traders; Perry is a disciple of Bastiat). The principal works on American economic history are those of A. S. Bolles, entitled *Industrial History of the United States*, and *Financial History of the United States*, 1774-1789, 1879.

We cannot here overlook a work like that of Mr Sidgwick (1883), to which we have already referred on a special point. It is impossible not to respect and admire the conscientious and penetrating criticism which he applies to the *a priori* system of economics in its most mature form. But it is open to question whether the task was wisely undertaken. It cannot be permanently our business to go on amending and limiting the Ricardian doctrines, and asking by what special interpretations of phrases or additional qualifications they may still be admitted as having a certain value. The time for a new construction has arrived; and it is to this, or at least to the study of its conditions, that competent thinkers with the due scientific preparation should now devote themselves. It is to be feared that Mr Sidgwick's treatise, instead of, as he hopes, "eliminating unnecessary controversy," will tend to revive the *sterile contestations* and *disuses disputes de mots*, which Comte censured in the earlier economists. It is interesting to observe that the part of the work which is, and has been recognized as, the most valuable is that in which, shaking off the fictions of the old school, he examines independently by the light of observation and analysis the question of the industrial action of Governments.

Let us briefly consider in conclusion, by the light of the preceding historical survey, what appear to be the steps in the direction of a renovation of economic science which are now at once practicable and urgent.

I. Economic investigation has hitherto fallen for the most part into the hands of lawyers and men of letters, not into those of a genuinely scientific class. Nor have its cultivators in general had that sound preparation in the

sciences of inorganic and vital nature which is necessary whether as supplying bases of doctrine or as furnishing lessons of method. Their education has usually been of a metaphysical kind. Hence political economy has retained much of the form and spirit which belonged to it in the 17th and 18th centuries, instead of advancing with the times, and assuming a truly positive character. It is homogeneous with the school logic, with the abstract unhistorical jurisprudence, with the, *a priori* ethics and politics, and other similar antiquated systems of thought; and it will be found that those who insist most strongly on the maintenance of its traditional character have derived their habitual mental pabulum from those regions of obsolete speculation. We can thus understand the attitude of true men of science towards this branch of study, which they regard with ill-disguised contempt, and to whose professors they either refuse or very reluctantly concede a place in their brotherhood.

The radical vice of this unscientific character of political economy seems to lie in the too individual and subjective aspect under which it has been treated. Wealth having been conceived as what satisfies desires, the definitely determinable qualities possessed by some objects of supplying physical energy, and improving the physiological constitution, are left out of account. Everything is gauged by the standard of subjective notions and desires. All desires are viewed as equally legitimate, and all that satisfies our desires as equally wealth. Value being regarded as the result of a purely mental appreciation, the social value of things in the sense of their objective utility, which is often scientifically measurable, is passed over, and ratio of exchange is exclusively considered. The truth is, that at the bottom of all economic investigation must lie the idea of the destination of wealth for the maintenance and evolution of a society. And, if we overlook this, our economics will become a play of logic or a manual for the market, rather than a contribution to social science; whilst wearing an air of completeness, it will be in truth one-sided and superficial. Economic science is something far larger than the catallactics to which some have wished to reduce it. A special merit of the physiocrats seems to have lain in their vague perception of the close relation of their study to that of external nature; and, so far, we must recur to their point of view, basing our economics on physics and biology as developed in our own time. Further, the science must be cleared of all the theologico-metaphysical elements or tendencies which still encumber and deform it. Teleology and optimism on the one hand, and the jargon of "natural liberty" and "indefeasible rights" on the other, must be finally abandoned.

Nor can we assume as universal premises, from which economic truths can be deductively derived, the convenient formulas which have been habitually employed, such as that all men desire wealth and dislike exertion. These vague propositions, which profess to anticipate and supersede social experience, and which necessarily introduce the absolute where relativity should reign, must be laid aside. The laws of wealth (to reverse a phrase of Buckle's) must be inferred from the facts of wealth, not from the postulate of human selfishness. We must bend ourselves to a serious direct study of the way in which society has actually addressed itself and now addresses itself to its own conservation and evolution through the supply of its material wants. What organs it has developed for this purpose, how they operate, how they are affected by the medium in which they act and by the co-existent organs directed to other ends, how in their turn they react on those latter, how they and their functions are progressively modified in process of time—these problems, whether statical or dynamical, are all questions of fact, as capable of being studied through observation

and history as the nature and progress of human language or religion, or any other group of social phenomena. Such study will of course require a continued "reflective analysis" of the results of observation; and, whilst eliminating all premature assumptions, we shall use ascertained truths respecting human nature as guides in the inquiry and aids towards the interpretation of facts. And the employment of deliberately instituted hypotheses will be legitimate, but only as an occasional logical artifice.

II. Economics must be constantly regarded as forming only one department of the larger science of sociology, in vital connexion with its other departments, and with the moral synthesis which is the crown of the whole intellectual system. We have already sufficiently explained the philosophical grounds for the conclusion that the economic phenomena of society cannot be isolated, except provisionally, from the rest,—that, in fact, all the primary social elements should be habitually regarded with respect to their mutual dependence and reciprocal actions. Especially must we keep in view the high moral issues to which the economic movement is subservient, and in the absence of which it could never in any great degree attract the interest or fix the attention either of eminent thinkers or of right-minded men. The individual point of view will have to be subordinated to the social; each agent will have to be regarded as an organ of the society to which he belongs and of the larger society of the race. The consideration of interests, as George Eliot has well said, must give place to that of functions. The old doctrine of right, which lay at the basis of the system of "natural liberty," has done its temporary work; a doctrine of duty will have to be substituted, fixing on positive grounds the nature of the social co-operation of each class and each member of the community, and the rules which must regulate its just and beneficial exercise.

Turning now from the question of the theoretic constitution of economics, and viewing the science with respect to its influence on public policy, we need not at the present day waste words in repudiating the idea that "non-government" in the economic sphere is the normal order of things. The *laissez faire* doctrine, coming down to us from the system of natural liberty, was long the great watchword of economic orthodoxy, and it had a special acceptance and persistence in England, in consequence of the political struggle for the repeal of the corn laws, which made economic discussion in this country turn almost altogether on free trade—a state of things which was continued by the effort to procure a modification of the protective policy of foreign nations. But it has now for some time lost the sacrosanct character with which it was formerly invested. This is a result not so much of scientific thought as of the pressure of practical needs—a cause which has modified the successive forms of economic opinion more than theorists are willing to acknowledge. Social exigencies will force the hands of statesmen, whatever their attachment to abstract formulas; and politicians have practically turned their back on *laissez faire*. The state has with excellent effect proceeded a considerable way in the direction of controlling, for ends of social equity or public utility, the operations of individual interest. The economists themselves have for the most part been converted on the question; amongst theorists Mr Herbert Spencer finds himself almost a *vox clamantis in deserto* in protesting against what he calls the "new slavery" of Governmental interference. He will protest in vain, so far as he seeks to rehabilitate the old absolute doctrine of the economic passivity of the state. But it is certainly possible that even by virtue of the force of the reaction against that doctrine there may be an excessive or precipitate tendency in the opposite direction. With the course of production or exchange considered in itself there will probably be in England little disposition

to meddle. But the dangers and inconveniences which arise from the unsettled condition of the world of labour will doubtless from time to time here, as elsewhere, prompt to premature attempts at regulation. Apart, however, from the removal of evils which threaten the public peace, and from temporary palliations to ease off social pressure, the right policy of the state in this sphere will for the present be one of abstention. It is indeed certain that industrial society will not permanently remain without a systematic organization. The mere conflict of private interests will never produce a well-ordered commonwealth of labour. *Freiheit ist keine Lösung*. Freedom is for society, as for the individual, the necessary condition precedent of the solution of practical problems, both as allowing natural forces to develop themselves and as exhibiting their spontaneous tendencies: but it is not in itself the solution. Whilst, however, an organization of the industrial world may with certainty be expected to arise in process of time, it would be a great error to attempt to improvise one. We are now in a period of transition. Our ruling powers have still an equivocal character: they are not in real harmony with industrial life, and are in all respects imperfectly imbued with the modern spirit. Besides, the conditions of the new order are not yet sufficiently understood. The institutions of the future must be founded on sentiments and habits, and these must be the slow growth of thought and experience. The solution, indeed, must be at all times largely a moral one: it is the spiritual rather than the temporal power that is the natural agency for redressing or mitigating most of the evils associated with industrial life.<sup>1</sup> In fact, if there is a tendency—and we may admit that such a tendency is real or imminent—to push the state towards an extension of the normal limits of its action for the maintenance of social equity, this is doubtless in some measure due to the fact that the growing dissidence on religious questions in the most advanced communities has weakened the authority of the churches, and deprived their influence of social universality. What is now most urgent is not legislative interference on any large scale with the industrial relations, but the formation, in both the higher and lower regions of the industrial world, of profound convictions as to social duties, and some more effective mode than at present exists of diffusing, maintaining, and applying those convictions. This is a subject into which we cannot enter here. But it may at least be said that the only parties in contemporary public life which seem rightly to conceive or adequately to appreciate the necessities of the situation are those that aim, on the one hand, at the restoration of the old spiritual power, or, on the other, at the formation of a new one. And this leads to the conclusion that there is one sort of Governmental interference which the advocates of *laissez faire* have not always discountenanced, and which yet, more than any other, tends to prevent the gradual and peaceful development of a new industrial and social system—namely, the interference with spiritual liberty by setting up official types of philosophical doctrine, and imposing restrictions on the expression and discussion of opinions.

It will be seen that our principal conclusion respecting economic action harmonizes with that relating to the theoretic study of economic phenomena. For, as we held

that the latter could not be successfully pursued except as a duly subordinated branch of the wider science of sociology, so in practical human affairs we believe that no partial synthesis is possible, but that an economic reorganization of society implies a universal renovation, intellectual and moral no less than material. The industrial reformation for which western Europe groans and travails, and the advent of which is indicated by so many symptoms (though it will come only as the fruit of faithful and sustained effort), will be no isolated fact, but will form one part of an applied art of life, modifying our whole environment, affecting our whole culture, and regulating our whole conduct—in a word, consciously directing all our resources to the conservation and evolution of humanity.

The reader is referred for fuller information to the following works on the history of political economy, all of which have been more or less, and some very largely, used in the preparation of the foregoing outline.

GENERAL HISTORIES.—*Histoire de l'Économie Politique en Europe depuis les anciens jusqu'à nos jours*, by Jérôme Adolphe Blanqui (1837-38); of which there is an English translation by Emily J. Leonard (1880). *Histoire de l'Économie Politique*, by Alban de Villeneuve-Bargemont (Brussels, 1839; Paris, 1841); written from the Catholic point of view. *View of the Progress of Political Economy in Europe since the 16th Century*, by Travers Twiss, D.C.L. (1847). *Die geschichtliche Entwicklung der Nationalökonomie und ihrer Literatur*, by Julius Kautz (2d ed. 1860); a valuable work marked by philosophical breadth, and exhibiting the results of extensive research, but too declamatory in style. *Kritische Geschichte der Nationalökonomie und der Socialismus*, by Emile Dühring (1871; 3d ed. 1879); characterized by its author's usual sagacity, but also by his usual perverseness and depreciation of meritorious writers in his own field. *Guida allo studio dell'Economia Politica*, by Luigi Cossa (1876 and 1878; Eng. trans. 1880). *Geschichte der Nationalökonomie*, by H. Eisenhart (1881); a vigorous and original sketch. And, lastly, a brief but excellent history by H. von Schöel in the *Handbuch der politischen Ökonomie* (really a great encyclopedia of economic knowledge in all its extent and applications), edited by Gustav Schenbergh (1882). To these histories proper must be added *The Literature of Political Economy*, by J. R. McCulloch (1845), a book which might with advantage be re-edited, supplemented where imperfect, and continued to our own time. Some of the biographical and critical notices by Eugène Daire and others in the *Collection des principaux Économistes* will also be found useful, as well as the articles in the *Dictionnaire de l'Économie Politique* of Coquelin and Guillaumin (1852-53), which is justly described by Jevons as "on the whole the best work of reference in the literature of the science."

SPECIAL HISTORIES.—*Italy*.—*Storia della Economia Pubblica in Italia, ossia Esposizione critica degli Economisti Italiani*, by Count Giuseppe Pecchiolo (1829), intended as an appendix to Baron Custodi's collection of the *Scrittori classici Italiani di Economia Politica*, 50 vols., comprising the writings of Italian economists from 1582 to 1804. There is a French translation of Pecchiolo's work by Leonard Gallois (1829). The book is not without value, though often superficial and rhetorical.

*Spain*.—*Storia della Economia Politica in Spagna* (1863), by M. Colmenero; rather a history of economy than of economics—of policies and institutions rather than of theories and literary works.

*Germany*.—*Geschichte der Nationalökonomie in Deutschland* (1874), by Wilhelm Roscher; a vast repository of learning on its subject, with occasional side-glances at other economic literatures. *Die deutsche Nationalökonomie in ihrer Hauptentwicklung*, by Moritz Meyer (3d ed., 1882); a useful handbook dealing almost exclusively with recent German speculation and policy.

*England*.—*Zur Geschichte der Englischen Volkswirtschaftslehre*, by W. Roscher (1851-52).

The reader is also advised to consult the articles of the present work which relate directly to the several principal writers on political economy. (J. K. L.)

POLK, JAMES KNOX (1795-1849), eleventh president of the United States of America, was of Scots-Irish

<sup>1</sup> The neglect of this consideration, and the consequent undue exaltation of state action, which, though quite legitimate, is altogether insufficient, appears to us the principal danger to which the contemporary German school of economists is exposed.

descent, his ancestors, whose name was Pollok, having emigrated from Ireland in the 18th century. He was the eldest of ten children, and was born 2d November 1795 in Mecklenburg county, North Carolina, from which his father, who was a farmer, removed in 1806 to the valley of the Duck river, Tennessee. At an early age he was

placed in a merchant's office, but as he showed a disinclination for business his father at last permitted him to begin preparatory studies for the university. In 1815 he entered the university of North Carolina, where in 1818 he graduated with the highest honours. Called to the bar in 1820, he speedily made for himself a high reputation, and in 1823 he entered the State legislature. In August 1825 he was chosen to represent his district in Congress, to which he was re-elected every succeeding two years until 1839. As a strong supporter of Democratic opinions he identified himself with every important discussion, and, though he was not a brilliant speaker, his solid abilities, extraordinary energy, and indomitable will soon gave him a place in the front rank of politicians. In 1835 he was chosen speaker of the House of Representatives, to which he was re-elected in 1837, and in 1839 he was elected governor of Tennessee. In 1844 he was the Democrat candidate for the presidency, and was chosen over Clay by a majority of sixty-five electoral votes. The election in great measure turned on the annexation of Texas, which was effected before his inauguration. One of the earliest questions with which his administration had to deal was the boundary of Oregon, which, although he had previously declared the title of the United States to Oregon to be "clear and undisputed," was finally fixed at the parallel of 49° instead of 54° 40'. Following the annexation of Texas came the Mexican war, resulting in the treaty of Guadalupe Hidalgo, 2d February 1848, by which New Mexico and California were ceded to the United States. Other important measures of his administration were the admission of Iowa and Wisconsin to the Union, the adoption of a low tariff in 1846, the organization of the department of the interior, and the adoption of the method of collecting Government revenues by specie without the aid of the banks. Polk retired from office 4th March 1849, and died in Nashville, 15th June of the same year.

*Life of the Hon. James Knox Polk, with a Compendium of his Speeches, 1844; Chase, History of the Polk Administration, 1850.*

**POLLACK** (*Gadus pollachius*), a species of cod-fish, abundant on rocky coasts of northern Europe, and extending as far south as the western parts of the Mediterranean, where, however, it is much scarcer and does not attain to the same size as in its real northern home. In Scotland and some parts of Ireland it is called *Lythe*. It is distinguished from other species of the genus *Gadus* by its long pointed snout, which is twice as long as the eye, with projecting lower jaw, and without a barbel at the chin. The three dorsal fins are composed of respectively 12, 18 or 20, and from 17 to 19 rays, and the two anal fins of 31 and 19 or 20. A black spot above the base of the pectoral fin is another distinguishing mark. Although pollack are well-flavoured fish, and smaller individuals (from 12 to 16 inches) excellent eating, they do not form any considerable article of trade, and are not preserved, the majority being consumed by the captors. Specimens of twelve pounds are common, but the species is said to attain 24 pounds in weight.

**POLLAN** (*Coregonus pollan*), a species of the Salmonoid genus *Coregonus* which has been found in the large and deep lochs of Ireland only. A full account of the fish by its first describer, W. Thompson, may be found in his *Natural History of Ireland*, vol. iv. p. 168.

**POLLIO**, CAIUS ASINIUS (76 B.C.—4 A.D.), a Roman orator, poet, and historian, who played a conspicuous part in the troubled history of his time, was born in 76 B.C. In his twenty-second year (54 B.C.) he impeached unsuccessfully C. Cato, who in his tribunate (58) had acted as the tool of the triumvirs. In the civil war between Caesar and Pompey, Pollio sided with Caesar, and after the successful campaigns against the remnants of the Pompeian party

in Africa and Spain he was raised to the prætorship, and received the command of the war in Spain against Sextus Pompeius. At the time of Caesar's assassination (March 15, 44) Pollio was in Spain. He was defeated by Sextus Pompeius and fled for his life. But by Lepidus's influence a peace was patched up and Sextus left Spain, while Pollio remained with three legions under him. During the war between Mark Antony and the senate, Pollio, in a letter to Cicero, declared himself on the side of the senate, but found pretexts for waiting to cast in his lot with the victor. In fact no sooner had Octavian become reconciled to Antony and Lepidus, and compelled the senate to rescind the decrees against them, than Pollio joined Lepidus with two legions. Antony, Lepidus, and Octavian now formed the triumvirate (43), and Pollio was nominated consul for the year 40 B.C. Meantime he was entrusted by Antony with the administration of Gallia Transpadana, and in superintending the distribution of the Mantuan territory amongst the veterans he used his influence to save from confiscation the property of the poet Virgil. When L. Antonius, brother of Mark Antony, revolted against Octavian and was besieged in Perusia (41–40), he entreated Pollio to hasten to his relief. Pollio advanced hesitatingly, but was fain to take refuge in Ravenna when Octavian marched to meet him. After the fall of Perusia Octavian and Antony were reconciled for a time by the peace of Brundisium, which Pollio helped to negotiate. He was now consul (40); Virgil's famous fourth eclogue is addressed to him in his consulship. Next year Pollio was sent by Antony against the Parthini, an Illyrian people who adhered to Brutus. He was successful, took the town of Salonæ, and celebrated a triumph in the same year. The eighth eclogue of Virgil is addressed to Pollio while engaged in this campaign. From the spoils of the war he constructed the first public library at Rome.<sup>1</sup> Thenceforward Pollio withdrew from active life and devoted himself to literature. When Octavian invited him to join in the war against Antony which ended in the battle of Actium, Pollio declined on the score of his former friendship with Antony. He seems to have maintained to a certain degree an attitude of independence if not of opposition towards Augustus. He lived to a green old age, and died in his villa at Tusculum in 4 A.D.

Pollio was a distinguished orator; his speeches showed ingenuity and care, but were marred by an affected archaism which rendered them somewhat crabbed and harsh. He wrote tragedies also, which Virgil declared to be worthy of Sophocles, and a prose history of the civil wars of his time from the first triumvirate (60 B.C.) down

<sup>1</sup> The library was in the Atrium Libertatis, which was also erected by Pollio (Isidor., *Orig.*, vi. 5; Sueton., *Aug.*, 29; Ovid, *Trist.*, iii. 1, 71). The situation of this Atrium is uncertain. There was an older Atrium Libertatis near the Forum (Cic. *Ad Att.*, iv. 16, 8), but we are precluded from identifying it with that of Pollio by the language of Isidore and Suetonius, who imply that Pollio built a new Atrium. Perhaps Pollio's Atrium was connected with the temple of Liberty on the Aventine (Livy, xxiv. 16); this would be strongly confirmed by Martial (xii. 3, 6), if we could be sure that his "domus alta Remi" referred to the Aventine. Mr A. W. Verrall (*Studies in Horace*, p. 113) has made it probable that Dion Cassius (xlix. 43) confused the Pollian with the Octavian library; and that accordingly 33 B.C. is the date of the dedication of the former library and not of the latter, which we know from Plutarch (*Marc.*, 30) to have been dedicated not earlier than 23 B.C., the date of Marcellus's death. But Mr Verrall's conjecture that "in the great reconstructions of Augustus" the Pollian library was absorbed in the Octavian seems negatived by Ovid, *Trist.*, iii. 1, 69–72, where "atria" certainly refers to the Pollian library, and "templa—vicino juncta theatro," probably refers to the Octavian library, which was in the Porticus Octaviæ, adjoining the twin temples of Jupiter and Juno, and close to the theatre of Marcellus (see Burn, *Rome and the Campagna*, p. 306 sq.). Pliny (*N. H.*, xxxvi. 24) also refers to "Pollionis Asini monumenta" as being distinct from the Porticus Octaviæ. Moreover, there is no evidence that the two libraries were even near each other; if the Pollian was on the Aventine, they were separated by nearly the whole breadth of the city.

to the death of Cicero (43 B.C.) or perhaps to the battle of Philippi (42 B.C.) or even later. This history, in the composition of which Pollio received assistance from the grammarian Atilius, was used as an authority by Plutarch and Appian. As a literary critic Pollio was very severe. He censured Sallust and Cicero and professed to detect in Livy's style certain provincialisms of his native Padua; he attacked the *Commentarii* of Julius Caesar, censuring their author of carelessness and credulity if not of deliberate falsification. Horace addressed one of his odes (iii. 1) to Pollio on the subject of his history. Pollio was the first Roman author who raised his writings to an audience of his friends, a practice which afterwards grew very common at Rome. All his writings are lost except a few fragments of his speeches (collected by Meyer, *Orat. Rom. Fragm.*), and three letters addressed to Cicero (*Clas. Ad Fam.* ii. 61-63).

**POLLNITZ, KARL LUDWIG, FREIHERR VON** (1692-1775), known as a writer of memoirs, was born on the 25th February 1692. His father, G. Bernhard von Pollnitz was a major-general and minister of state in the electorate of Brandenburg. Pollnitz was a man of restless and adventurous disposition, and after squandering his fortune travelled from court to court, his pleasant manners generally securing for him a kind reception. He was made reader to Frederick the Great, and afterwards the director of a theatre; but before accepting these appointments he had served as a soldier in Austria, the States of the Church, and Spain. He was repeatedly converted to Catholicism and re-converted to the Reformed faith; but he died a Catholic on the 23rd June 1775.

The most famous work attributed to him is *Le Saxe gréciste*, which contains an account of the private life of Augustus of Saxony; but it has been doubted whether he was the author of this book. His contemporaries expressed much admiration for the lively style of his *Lettres d'histoire, des romans, et de plusieurs de ses amis de la relation de ses premiers voyages*, and general interest was excited by his *État présent de la cour de Saxe sous le règne d'Auguste III., roi de Pologne*. He was probably the author of the *Histoire comique de la duchesse d'Hamilton, épouse de George I. roi de la Grande-Bretagne*. After his death Brumm issued *Mémoires de Pollnitz pour servir à l'histoire des quatre derniers souverains de la nation de Brandebourg*, *revue de Prusse*.

**POLLOK, ROBERT** (1793-1827), was the author of *The Course of Time*, a poem that has passed through many editions, and is still a favourite in serious households in Scotland. The son of a small farmer, he was born in 1793 at Moorhouse, in the parish of Eaglesham in Renfrewshire, was originally destined for the plough, but trained himself for the university, took his degree at Glasgow, and studied for the ministry of the United Secession Church. Along with the very general ambition to wag his head in a pulpit he had a specific literary ambition; he published *Tales of the Covenanters* while he was a divinity student, and planned and completed a poem on the spiritual life and destiny of man. This was the *Course of Time*. The unfortunate poet died within six months of its publication, at the age of twenty-nine. Excessive study had quickened a tendency to consumption. The poem was published in March 1827, and at once became popular. It is written in blank verse in ten books, in the poetic diction of the 18th century, but with abundance of enthusiasm, impassioned elevation of feeling, and copious force of words and images. The poet's view of life was strongly Calvinistic.

**POLLOKSHAW, a burgh of barony in Renfrewshire, Scotland, situated near the White Cart, on the Glasgow and Kilmarnock Railway, 2½ miles south by west of Glasgow, of which it is now reckoned a suburb, connected by tramway. The streets are irregular, but contain many good houses and shops. The principal buildings are the town-hall, the mechanics' institute, and the public library and reading-room. The staple industries are cotton-spinning, hand and power-loom weaving of silk and cotton fabrics, dyeing, bleaching, and calico-printing. There are also paper works, potteries, and large engineering works. The town was created a burgh of barony by royal charter in 1813, and is governed by a provost, a bailie**

and six councillors. Population in 1871, 8921; in 1881, 9353.

**POLLUX. See CASTOR AND POLLUX.**

**POLLUX, JULIUS**, of Naxos in Egypt, a Greek sophist of the 2d century. His education was begun by his father, a man of literary culture, and was continued by one Hadrian, but he is said neither to have attained to the excellencies nor fallen into the defects of his master. He taught at Athens, where, according to Philostratus, he was appointed to the professorship by the emperor Commodus on account of his melodious voice. He died at the age of fifty-eight, leaving a son behind him. Suidas gives a list of his rhetorical works, none of which have survived. Philostratus (*Vit. Soph.* ii. 12) recognizes his natural abilities, but speaks of his rhetoric in very moderate terms. He was ridiculed by Athenodorus, a contemporary teacher at Athens. It is a disputed point whether or not he is the butt of Lucian's scathing satire in the *Leriphanes* and *Teacher of Rhetoric*. In the *Teacher of Rhetoric* Lucian lashes a vile and ignorant person who gains a reputation as an orator by sheer effrontery; the application of this—probably grossly exaggerated—portrait to Pollux derives some colour from the remark of Philostratus that the speeches of Pollux were more remarkable for boldness than art. The *Leriphanes*, a satire upon the use of obscure and obsolete words, may conceivably have been directed against Pollux as the author of the *Onomasticon*. This work, which we still possess, is a Greek dictionary in ten books dedicated to Commodus, and arranged not alphabetically but according to subject-matter. Though mainly a dictionary of synonyms and phrases, it supplies much rare and valuable information on many points of classical antiquity. It also contains numerous fragments of writers now lost.

The first book treats of the gods and their worship, kings, speed and slowness, drying, moist and aridness, fertility and barrenness, times and seasons, houses, ships, war, horses, agriculture, the parts of the plough and the yaggon, bees. Book ii. treats of the ages and names of men, the parts of his body, his mind and soul, &c.; book iii. of kinship, marriage, citizenship, friendship, love, the relation of master and slave, mines, journeying, rivers, health, sickness, wealth, poverty, &c.; book iv. of the sciences and arts; book v. of the class, animals, compound words, love and hate, names, fair greetings, inscriptions, &c.; book vi. of feasts, wine, food, the relative man, the farmer, the passionate man, crimes, words compounded with *too*, *oxy*, &c., gifts, laughter and weeping &c.; book vii. of modes; book viii. of law and justice, magistracies, popular assemblies, &c.; book ix. of cities, crimes, games, synopses of likeness and unlikeness, &c., compounds in *er*; book x. of vessels, instruments, and tools. The chief editions of Pollux's *Onomasticon* are those of Aldus (Venice, 1562); J. H. Lefebvre and Tib. Hemsterhuis (Amsterdam, 1706); W. Dindorf (Leipzig, 1824), containing the notes of previous commentators; Im. Bekker (Berlin, 1846), containing the Greek text only.

**POLO.** This game, which is a species of "hockey on horseback," is of Eastern origin, and seems to have been a favourite pastime in Persia, Tartary, and the frontiers of India from prehistoric times. Every district has a different name for the game, and the rules under which it is played, although substantially identical, vary considerably on minor points. Thus in Little Tibet, Ladakh, and the adjacent districts the ground used is in the form of a parallelogram some hundred yards long with a goal at each end about 50 feet wide. Amongst the Manipuris, a semi-independent tribe on the north-east frontier of India, by whom the game is known as "kurjai," the ground is about 120 yards by 50 yards and the whole of each end forms a goal. In other places the goals are about 400 yards apart, and the ground is 120 yards wide at each end, increasing in width towards the centre.

In some of the early matches in the United Kingdom the ground was about 400 yards long and 200 yards wide, the width of the goal being from 30 to 35 yards. Under the present rules of the Hurlingham Club, which is now

the principal authority on the game, it is provided that the goals shall be "not less than 250 yards apart and that each goal shall be 8 yards wide." The English name of the game is perhaps derived from "pulu," which is the Tibetan for a ball, and the pastime itself reached India from Persia through Afghanistan. It speedily gained favour with the officers of British cavalry regiments quartered in India, and was introduced into the United Kingdom in 1871 by the 10th Hussars. As far as can be ascertained the first match played on English soil took place at Aldershot in the spring of that year. This, however, is not absolutely certain, as no records seem to have been preserved of the early contests.

Under the rules of the game as now played the opposing parties may consist of from three to six players a side, the number in all matches for cups or prizes being limited to four. Each of the players is mounted on a pony which must not exceed fourteen hands and which must be free from any vice. As the description of the game as "hockey on horseback" would imply, the object of the pastime is to force a ball by means of a stick, with which each player is furnished, through the goal of the opposing side. The size of the ball is 3 inches in diameter, and the sticks are 4 feet long with a cross piece at one end for the purpose of striking the ball. At the commencement of a game each side takes up its position behind the goal posts. A player on each side is appointed as goal-keeper. On a flag being dropped to notify the commencement of the game, the other players gallop towards the centre of the ground at full speed, their object being to reach the ball first and drive it in the direction of the opposite goal. When a ball is hit out of bounds it is thrown into play again by one of the umpires, of whom there is one appointed for each side before the commencement of a match. When a ball is hit beyond the goal without passing through it the side defending goal is entitled to a "hit off," which must be made from the goal line. It is allowable in the course of play to impede an adversary and hinder his stroke by hooking his stick, but this must not be done either under or over his pony. Whilst it is permissible for a player to interpose his pony before his antagonist so as to prevent the latter reaching the ball, it is expressly forbidden to cross another player in possession of the ball except at such a distance as to avoid all possibility of collision. Should a player break his stick or have it broken he must ride to the appointed place where the sticks are kept and take one, and on no account is one to be brought to him. If he drops his stick he must dismount and pick it up, and is not allowed to hit the ball whilst dismounted. If a player is in front of a player of his own side who hits the ball, and has not two—or in case of matches of four a side, one—of the opposing side between him and the hostile goal, and has not come through the "bully," he is "off side." He does not then come "on his side" until the ball has been hit or hit at by the opposing side, or until the player on his own side who made the hit passes him. As long as he is "off side" he may not in any way impede a player of the opposite side. In all matches the duration of play is 1 hour 10 minutes, with an interval of 5 minutes after each 20 minutes play.

Owing to the expense of maintaining a specially trained stud of ponies and a prepared ground for the pastime, the pursuit of the game of polo has always been confined to the wealthier classes in England. Its chief supporters are the younger members of the aristocracy and the officers of British cavalry regiments.

POLO, MARCO (c. 1254–1324), the Venetian, the most famous perhaps of all travellers. His history needs to be introduced by some account of the preceding generation of

his family, and of the state of the world which rendered their and his extensive travels possible.

Under CHINA, in the introductory portion (vol. v. 627 sq.) we have briefly indicated the circumstances which in the last half of the 13th century and first half of the 14th threw Asia open to Western travellers to a degree unknown before and since. We first hear of the Polo family in the year 1260. The vast wave of Tartar conquest, set in motion by Jenghiz Khan, and continuing to advance for some years after his death, had swept away all political barriers from the China Sea to the western frontier of Russia. This huge extent of empire continued for a time to own a supreme chief in the Great Khan, the head of the house of Jenghiz, whose headquarters were in the Mongolian steppe. Practically indeed the empire soon began to split up into several great monarchies under the descendants of his four sons, in order of age Juji, Jagatai, Oghotai, and Tuli. At the date we have named the supreme khanate had recently devolved upon Kublai, son of Tuli, and, after the founder, the ablest of his house. In the beginning of his reign Kublai carried out the transfer of the seat of rule from Karakorum on the northern verge of the Mongolian plains to the populous and civilized regions that had been conquered in the further East, a transfer which eventually converted the Tartar khan into a Chinese emperor.

Barka, the son of Juji, and the first of the house of Jenghiz to turn Moslem, reigned on the steppes of the Volga, where a standing camp, which eventually became a great city under the name of Sarai, had been established by his brother and predecessor Batu.

Hulagu, a younger brother of Kublai, after taking Baghdad, and putting the caliph Mosta'sim to death, had become practically independent ruler of Persia, Babylonia, Mesopotamia, and Armenia,—though he and his sons and his sons' sons continued to the end of the century to stamp the name of the Great Khan upon their coins, and to use the Chinese seal of state which he conferred.

The house of Jagatai had settled upon the pastures of the Ili and in the valley of the Jaxartes, and ruled also the populous cities of Samarkand and Bokhara.

Kaidu, grandson of Oghotai, who had been the immediate successor of Jenghiz, refused to recognize the transfer of supreme authority to his cousins, and through the long life of Kublai was a thorn in the side of the latter. His immediate authority was exercised in what we should now call Chinese Turkestan and Southern Central Siberia.

Northern China had been conquered by Jenghiz and his successors from the Tartar dynasty called *Kin* or "Golden," who had held it about a century. But southern China still remained in the hands of the native dynasty, whose capital was the great city now known as Hang-chow-foo. Their dominion was still substantially intact, but its subjugation was a task to which Kublai soon turned his attention, and it became the most prominent transaction of his reign.

In India the most powerful sovereign was the Turk sultan of Delhi; but, though both Sind and Bengal owned his supremacy, no part of peninsular India had yet been invaded. The Dravidian kingdoms of the south were still untouched by foreign conquest, and the accumulated gold of ages lay in their temples and treasures an easy prey for the coming Moslem.

In the Indo-Chinese peninsula and the Eastern Islands a variety of kingdoms and dynasties were expanding and contracting, of which we have but dim and shifting glimpses. Their advance in wealth and art, far beyond what the present state of those regions would suggest, is attested by the vast and magnificent mediæval remains of architecture which are found at intervals over both the

Indo-Chinese continental countries and the islands, as at Pagán in Burmah, at Ayuthia in Siam, at Ongkor and many other places in Camboja, at Borobodor and Brambanan in Java. All these remains are deeply marked by Hindu influence.

Venetian genealogies and traditions of uncertain value trace the Polo family to Sebennico in Dalmatin, and before the end of the 11th century names of its members are found in the Great Council of the republic. But the ascertained line of the traveller begins only with his grandfather. Andrea Polo of S. Felice was the father of three sons, Marco, Nicolo, and Maffeo, of whom the second was the father of the subject of this article. They were presumably "noble," i.e., belonging to the families who had seats in the Great Council, and were enrolled in the *Libro d'Oro*; for we know that Marco the traveller is officially so styled (*nobilis vir*). The three brothers were engaged in commerce; the elder Marco, resident apparently in Constantinople and in the Crimea, does not enter into the history.

In 1260 we find Nicolo and Maffeo at Constantinople. How long they had been absent from Venice we do not know. Nicolo was a married man, and had left his wife there. In the year named the two brothers went on a speculation to the Crimea, whence a succession of chances and openings carried them to the court of Barka Khan at Sarai, and further north, and eventually across the steppes to Bokhara. Here they fell in with certain envoys who had been on a mission from the Great Khan Kublai to his brother Hulagu in Persia, and by them were persuaded to make the journey to Cathay in their company. And thus the first European travellers of whom we have any knowledge reached China. Kublai, when they reached his court, was either at CAMALUC (*q.r.*), i.e., Peking, which he had just rebuilt on a vast scale, or at his beautiful summer seat at Shangtu in the country north of the great wall ("In Xanadu did Kubla Khan," &c.). It was the first time that the khan, a man full of energy and intelligence, had fallen in with European gentlemen. He was delighted with the Venetian brothers, listened eagerly to all that they had to tell of the Latin world, and decided to send them back as his envoys to the pope, with letters requesting the despatch of a large body of educated men to instruct his people in Christianity and in the liberal arts. The motive of the khan's request was doubtless much the same that some years back influenced the black king of Uganda on Lake Nyanza to make a similar request through the traveller Stanley. With Kublai, as with his predecessors, religion was chiefly a political engine. The khan must be obeyed; how man should worship God was no matter to him. But Kublai was the first of his house to rise above the essential barbarism of the Mongols, and he had been able enough to discern that the Christian church could afford the aid he desired in taming his countrymen. It was only when Rome had failed lamentably to meet his advances that he fell back upon the lamas and their trumpery as, after a fashion, civilizing instruments.

The brothers arrived at Acre in April 1269. They learned that Clement IV. had died the year before, and no new pope had yet been chosen. So they went home to Venice, where they found that Nicolo's wife was dead, but had left a son Marco, now a fine lad of fifteen.

The papal interregnum was the longest that had been known, at least since the dark ages. After the Polos had spent two years at home there was still no pope; and the brothers resolved on starting again for the East, taking young Mark with them. At Acre they took counsel with an eminent churchman, Tedaldo, archdeacon of Liège, and took from him letters to authenticate the causes that had

hindered their mission. They had not yet left Acre on the Cilician coast (then one of the chief points for the arrival and departure of the land-trade of Asia), when news overtook them that a pope had been elected in the person of their friend Archdeacon Tedaldo. They hastened back to Acre, and at last were able to execute Kublai's commission and to obtain a papal reply. But, instead of the hundred teachers asked for by the Great Khan, the new pope (styled Gregory X.) could supply but two Dominicans; and these lost heart and turned back, when they had barely taken the first step of their journey.

The second start from Acre must have taken place about November 1271; and from a careful consideration of the indications and succession of chapters in Marco Polo's book, it would seem that the party proceeded from Acre to Sivas, and then by Mardin, Mosul, and Baghdad to Hormuz at the mouth of the Persian Gulf (see ORMUS), with the purpose of going on to China by sea; but that, some obstacle having interfered which compelled them to abandon this plan, they returned northward through Persia. Traversing Kerman and Khorasan they went on to Balkh and Badakhshan, in which last country—an Oriental Switzerland, as it has been called—they were long detained by the illness of young Marco. In a passage touching on the charming climate of the hills of Badakhshan, Marco breaks into an enthusiasm which he rarely betrays, but which is easily understood by those who have known what it is, with fever in the blood, to escape to the exhilarating air and fragrant pine-groves of the Himalaya. They then ascended the upper Oxus through Wakhán to the plateau of Pamir (a name first heard in Marco's book). Those regions, so attractive to geographers, were never described again by any European traveller till the spirited expedition in 1838 of that excellent officer the late Lieutenant John Wood of the Indian navy, whose narrative abounds in the happiest incidental illustration of Marco Polo's chapters. Crossing the Pamir highlands, the travellers descended upon Kashgar, whence they proceeded by Yarkand to Khotan. These are regions which remained almost absolutely closed to our knowledge till within the last twenty years, when the temporary overthrow of the Chinese power, and the enterprise of travellers like the late Mr Johnson and Mr Robert Shaw, followed by the missions of Sir Douglas Forsyth and his companions, and of Mr Ney Elias, again made them known.

From Khotan they passed on to the vicinity of Lake Lop (or Lob), reached still more recently, for the first time since Marco Polo's journey, by the indefatigable Russian officer Prejevalsky, in 1871. Thence the great desert of Gobi was crossed to Tangut, as the region at the extreme north-west of China, both within and without the Wall, was then called.

In his account of the passage of the Gobi, or desert of Lop, as he calls it, Polo gives some description of the terrors with which the suggestions of solitude and desolation have peopled such tracts in most parts of the world, a description which reproduces with singular identity that of the Chinese pilgrim HWEN T'SANG (*q.r.*), in passing the same desert in the contrary direction six hundred years before.

The Venetians, in their further journey, were met and welcomed by the Great Khan's people, and at last reached his presence at Shangtu, in the spring of 1275. Kublai received them with great cordiality, and took kindly to young Mark, by this time about one and twenty years of age. The "young bachelor," as the book calls him, applied himself diligently to the acquisition of the diverse languages and written characters chiefly in use among the multifarious nationalities included in the khan's court and administration; and Kublai, seeing that he was both

clever and discreet, soon began to employ him in the public service. M. Pauthier, his most recent French editor, has found in the Chinese annals a record that in the year 1277 a certain Polo was nominated as a second-class commissioner or agent attached to the imperial council, a passage which we may without scruple apply to the young Venetian.

His first public mission was one which carried him through the provinces of Shansi, Shensi, and Szechuen, and the wild country on the coast of Tibet, to the remote province of Yunnan, called by the Mongols *Karâjang*, and into northern Burmah (Mien). Marco, during his stay at court, had observed the khan's delight in hearing of strange countries, of their manners, marvels, and oddities, and had heard his frank expressions of disgust at the stupidity of envoys and commissioners who could tell of nothing but their official business. And he took care to store his memory or his note-book with all curious facts that were likely to interest Kublai, and these, on his return to court, he related with vivacity. This first journey led him through a country which twenty years ago was an almost absolute *terra incognita*,—though within that time we have learned much regarding it through the journeys of Cooper, Garnier, Richthofen, Gill, Baber, and others. In this region there existed, and there still exists, in the deep valleys of the great rivers, and in the alpine regions which border them, a vast ethnological garden, as it were, of tribes of very various origin, and in every stage of semi-civilization or barbarism; and these afforded many strange products and eccentric traits of manners to entertain the emperor.

Marco rose rapidly in favour, and was often again employed on distant missions, as well as in domestic administration; but we are able to gather but few details of his employment. At one time we know that he held for three years the government of the great city of Yangchow; on another occasion we find him visiting Karakorum on the north of the Gobi, the former residence of the Great Khans; again in Champa, or southern Cochin-China; and, once more, on a mission to the southern states of India. We are not informed whether his father and uncle shared in such employments, though they are specially mentioned as having rendered material service to the khan, in forwarding the capture of the city of Siangyang-foo (on the Han river) during the war against southern China, by the construction of powerful artillery engines—a story, however, perplexed by chronological difficulties, which here we must pass over.

In any case the elder Polos were gathering wealth, which they longed to carry back to their home in the lagoons, and after their long exile they began to dread what might follow old Kublai's death. The khan, however, was deaf to all suggestions of departure; and but for a happy chance we should have lost our mediæval Herodotus.

Arghun, khan of Persia, the grandson of Kublai's brother Hulagu, lost in 1286 his favourite wife, Bolghana (*Bulughân* or "Sable") by name. Her dying injunction was that her place should be filled only by a lady of her own Mongol tribe. Ambassadors were despatched to the court of Khânbâligh to obtain such a bride. The message was courteously received, and the choice fell on the lady Cocachin (*Kukáchim*), a maiden of seventeen, "moult bele dame et avenant." The overland road from Peking to Tabriz was not only of portentous length for so delicate a charge, but was then imperilled by war; so the envoys of Arghun proposed to return by sea. Having made acquaintance with the Venetians, and eager to profit by their experience, especially by that of Marco, who had just returned from his mission to India, they begged the khan

as a favour to send the Franks in their company. He consented with reluctance, but fitted out the party nobly for the voyage, charging them with friendly messages to the potentates of Christendom, including the king of England. They appear to have sailed from the port of Chwan-chow (or CHINCHOW, *q.v.*) in Fuhkien, which was then the great haven of foreign trade, and was known to Western strangers as Zaitûn, in the beginning of 1292. The voyage was an ill-starred one, involving long detention on the coast of Sumatra, and in the south of India; and two years or more passed before they arrived at their destination in Persia. Two out of the three envoys, and a vast proportion of their suite perished by the way; but the three hardier Venetians survived all perils, and so did the young lady, who had come to look on them with filial regard. It proved that Arghun Khan had been dead even before they quitted China; his brother reigned in his stead; and his son Ghazan succeeded to the lady's hand. She took leave of the kindly Venetians, not without tears; they went on to Tabriz, and after a long delay there departed for Venice, which they seem to have reached about the end of 1295.

The first biographer of Marco Polo was the famous geographical collector John Baptist Ramusio, who wrote more than two centuries after the traveller's death. Facts and dates sometimes contradict his statements, but his story is told with great life and picturesqueness, and we need not hesitate to accept, at least as a genuine tradition, a romantic story, too long for repetition here, of the arrival of the Polos at their family mansion in the parish of St John Chrysostom, of their appearance at its door in worn and outlandish garb, of the scornful denial of their identity, and of the shrewd stratagem by which they secured acknowledgment from the society of Venice.

Some years pass ere we hear more of Marco Polo; and it is then in a militant capacity.

Jealousies, always too characteristic of Italian communities, were in the case of Venice and Genoa sharpened by direct commercial rivalry, and had been growing in bitterness throughout the 13th century. In 1298 the Genoese made preparations on a great scale to strike a blow at their rivals on their own ground, and a powerful fleet of galleys, under Lamba Doria as admiral, made straight for the Adriatic. Venice, on hearing of the Genoese armament, hastily equipped a fleet still more numerous, and placed it under the command of Andrea Dandolo. The crew of a Venetian galley at this time amounted, all told, to 250 men, under a *comito* or master, but besides this officer each galley carried a *sopracomito* or gentleman commander, who was usually a noble. On one of the galleys of Dandolo's fleet went Marco Polo in this last capacity.

The hostile fleets met before the island of Curzola on the 6th September, and engaged next morning. The battle ended in a complete victory to Genoa, the details of which may still be read, inscribed on the façade of the church of St Matthew in that city. Sixty-six Venetian galleys were burnt in the Bay of Curzola, and eighteen were carried to Genoa, with 7000 prisoners, one of whom was Marco Polo. The captivity was of less than a year's duration; for by the mediation of Milan peace was made, on honourable terms for both republics, by July 1299; and Marco Polo was probably restored to his family during that or the following month.

But his captivity was memorable as being the means of bringing about the record of his remarkable experiences in the East. Up to this time he had doubtless often related his stories of Cathay among his friends; and from these stories indeed, and the frequent employment in them (as it would seem) of a numerical expression unfamiliar in those days, he had acquired the nickname of *Marco*

*Millioni*. Yet it would seem that he had committed nothing to writing.

The narratives not only of Marco Polo but of several other famous mediæval travellers (*e.g.*, Ibn Batuta, Friar Odoric, Nicolo Conti) seem to have been extorted from them by a kind of pressure, and committed to paper by other hands. This indicates indeed how little the literary ambition which besets so many modern travellers weighed with the class in those days. It is also perhaps an example of that intense dislike to the use of pen and ink which still prevails among ordinary respectable folk on the shores of the Mediterranean.

But, in the prison of Genoa, Marco Polo fell in with a certain person of writing propensities, Rusticiano or Rustichello of Pisa, who also was a captive of the Genoese. His name is known otherwise to literary antiquaries as that of a respectable kind of literary hack, who abridged and recast several of the French romances of the Arthurian cycle which were then in fashion. He it was, apparently, who persuaded Marco Polo to defer no longer the commitment to paper of his wonderful experiences. In any case it was he who wrote down these experiences at Marco's dictation; and he is the man therefore to whom we owe the existence of this record, and possibly the preservation even of the traveller's name and memory.

We learn but little of Marco Polo's personal or family history after this captivity; but we know that at his death he left a wife, Donata by name (perhaps of the family of Loredano, but this is uncertain), and three daughters, Fantina and Bellela married, the former to Marco Bragadino, and Moreta then a spinster, but married at a later date to Ranuzzo Dolfino. One last glimpse of the traveller is gathered from his will, which is treasured in the library of St Mark's. On the 9th January 1324 the traveller, now in his seventieth year, and sinking day by day under bodily infirmity, sent for a neighbouring priest and notary to make his testament. We do not know the exact time of his death, but it fell almost certainly within the year 1324, for we know from a scanty series of documents, commencing in June 1325, that he had at the latter date been some time dead. He was buried in accordance with his will, in the church of St Lorenzo, where the family burying-place was marked by a sarcophagus, erected by his filial care for his father Nicolo, which existed till near the end of the 16th century. On the renewal of the church in 1592 this seems to have been cast aside and lost.

The copious archives of Venice have yielded up a few traces of our traveller. Besides his own will just alluded to, there are in the library the wills of his uncle Marco and of his younger brother Maffeo; a few legal documents connected with the house property in St John Chrysostom, and other papers of similar character; and two or three entries in the record of the *Maggior Consiglio*. We have mentioned the sobriquet of Marco *Millioni* which he got from his young townsmen. Ramusio tells us that he had himself noted the use of this name in the public books of the commonwealth, and this statement has been verified of late years in one of those entries in the books of the Great Council (dated 10th April 1305), which records as one of the securities in a certain case the "*Nobilis vir Marchus Paulo Million*." It is alleged that long after the traveller's death there was always in the Venetian masques one individual who assumed the character of Marco *Millioni*, and told Munchausen-like stories to divert the vulgar. Such, if this be true, was the honour of our great man in his own country. One curious parchment among those preserved is the record of the judgment of the court of requests (*Curia Petitionum*) upon a suit brought by the "*Nobilis Vir Marcus Polo*" against Paulo Girardo, who had

been an agent of his, to recover the value of a certain quantity of musk for which Girardo had not accounted. Another curious document brought to light within the last few years is a catalogue of certain curiosities and valuables which were collected in the house of the unhappy Marino Faliero, and this catalogue comprises several objects that Marco Polo had given to one of the Faliero family. Among these are two which would have been of matchless interest had they survived, viz.—"*Unum anulum con inscriptione que dicit Cuibile Can Marco Polo, et unum torques cum multis animalibus Tartarorum sculptis que res donum dedit predictus Marcus quidam (cuidam) Faletrorum.*"

The most tangible record of Polo's memory in Venice is a portion of the Ca' Polo—the mansion (there is every reason to believe) where the three travellers, after their absence of a quarter century, were denied entrance. The court in which it stands was known in Ramusio's time as the *Corte del Millioni*, and now is called *Corte Sabbionera*. That which remains of the ancient edifice is a passage with a decorated archway of Italo-Byzantine character pertaining to the 13th century. With this exception, what was probably the actual site of the mansion is now occupied by the Malibran theatre.

No genuine portrait of Marco Polo exists. There is a medallion portrait on the wall of the Sala dello Scudo in the ducal palace, which has become a kind of type; but it is a work of imagination no older than 1761. The oldest professed portrait is one in the gallery of Monsignor Badia at Rome, which is inscribed *Marcus Polus Venetus Totius Orbis et Indie Peregrator Primus*. It is a good picture, but evidently of the 16th century at earliest, and the figure is of the character of that time. The Europeans at Canton have attached the name of Marco Polo to a figure in a Buddhist temple there containing a gallery of "Arhans" or Buddhist saints, and popularly known as the "temple of the five hundred gods." There is a copy of this at Venice, which the Venetian municipality obtained on the occasion of the Geographical Congress there in 1881. But the whole notion was a groundless fancy.

The book indited by Rusticiano the Pisan, which has preserved Marco Polo's fame, consists essentially of two parts. The first, or prologue, as it is termed, is the only part unfortunately which consists of actual personal narrative. It relates in a most interesting, though too brief, fashion the circumstances which led the two older Polos to the khan's court, with those of their second journey accompanied by Marco, and of the return to the West by the Indian seas and Persia. The second and staple part of the book consists of a long series of chapters of very unequal length and unsystematic structure, descriptive of the different states and provinces of Asia, with occasional notices of their sights and products, of curious manners and remarkable events, and especially regarding the emperor Kublai, his court, wars, and administration. A series of chapters near the close treats in a wordy and monotonous manner of sundry wars that took place between various branches of the house of Jenghiz in the latter half of the 13th century. This last series is either omitted or greatly curtailed in all the MS. copies and versions except one.

It was long a doubtful question in what language the work was originally written. That this had been some dialect of Italian was a natural presumption, and a contemporary statement could be alleged in its favour. But there is now no doubt that the original was French. This was first indicated by Count Baldelli-Boni, who published an elaborate edition of two of the Italian texts at Florence in 1827, and who found in the oldest of these indisputable signs that it was a translation from the French. The argument has since been followed up by others; and a manuscript in rude and peculiar French, belonging to the National Library of Paris, which was printed by the Société de Géographie in 1824, has been demonstrated (as we need not hesitate to say) to be either the original or a very close transcript of the original dictation. A variety of its characteristics are strikingly indicative of the unrevised product of dictation, and are such as would necessarily have disappeared either in a translation or in a revised copy. Many illustrations could be adduced of the fact that the use of French was not a circumstance of a surprising or unusual nature; for the language had at that time, in some points of view, even a wider diffusion than at pre-

sent, and examples of its literary employment by writers who were not Frenchmen are very numerous. It is superfluous to allege instances here, when we observe that Rosticiano himself, the scribe of the narrative, was a compiler of French romances.

Some eighty MSS. of the book are known, and their texts exhibit considerable differences. These fall under four principal types. Of these type i. is found completely only in that old French codex which has been mentioned. Type ii. is shown by several valuable MSS. in purer French, the best of which formed the basis of the edition prepared by the late M. Pauthier in 1865. It exhibits a text pruned and revised from the rude original, but without any exactness, though perhaps under some general direction by Marco Polo himself, for an inscription prefixed to one of the MSS. records the presentation of a copy by the traveller himself to the Seigneur Thibault de Cepoy, a distinguished Frenchman known to history, at Venice in the year 1306. Type iii. is that of a Latin version prepared in Marco Polo's lifetime, though without any sign of his cognizance, by Francesco Pipino, a Dominican of Bologna, and translated from an Italian copy. In this, condensation and curtailment are carried a good deal further than in type ii. Some of the forms under which this type appears curiously illustrate the effects of absence of effective publication, not only before the invention of the press, but in its early days. Thus the Latin version published by Gryneus at Basel in the *Novus Orbis* (1532) is different in its language from Pipino's, and yet is clearly traceable to that as its foundation. In fact it is a retranslation into Latin from some version of Pipino (Marsden thinks the Portuguese printed one of 1502). It introduces also changes of its own, and is quite worthless as a text; and it is curious that Andreas Müller, who in the 17th century took much trouble with editing Polo according to his lights, should have unfortunately chosen as his text this fifth-hand version. It may be added that the French editions published in the middle of the 18th century were translations from Gryneus's Latin. Hence they complete this curious and vicious circle of translation—French, Italian, Pipino's Latin, Portuguese, Gryneus's Latin, French.

The fourth type of text deviates largely from those already mentioned; its history and true character are involved in obscurity. It is only represented by the Italian version prepared for the press by G. B. Ramusio, with most interesting preliminary dissertations, and published at Venice two years after his death, in the second volume of the *Navigazioni e Viaggi*. Its peculiarities are great. Ramusio seems to imply that he made some use of Pipino's Latin, and various passages confirm this. But many new circumstances, and anecdotes occurring in no other copy, are introduced; many names assume a new shape; the whole style is more copious and literary in character than that of any other version. Whilst a few of the changes and interpolations seem to carry us further from the truth, others contain facts of Asiatic nature or history, as well as of Polo's alleged experiences, which it is extremely difficult to ascribe to any hand but the traveller's own.

We recognize to a certain extent tampering with the text, as in cases where the proper names used by Polo have been identified, and more modern forms substituted. In some other cases the editorial spirit has been more meddling and has gone astray. Thus the age of young Marco has been altered to correspond with a date which is itself erroneous. Ormus is described as an island, contrary to the old texts, and to the facts of its position in Polo's time. In speaking of the oil-springs of Caucasus the phrase "camel-loads" has been substituted for "ship-loads," in ignorance that the site was Baku on the Caspian.

But on the other hand there are a number of new circumstances certainly genuine, which can hardly be ascribed to any one but Polo himself. We will quote one only. This is the account which Ramusio's version gives of the oppressions exercised by Kublai's Mohammedan minister Ahmed, telling how the Cathayans rose against him and murdered him, with the addition that Messer Marco was on the spot when all this happened. Not only is the whole story in substantial accordance with the Chinese annals, even to the name of the chief conspirator (*Vanchu* in Ramusio, *Wang-chu* in the Chinese records), but the annals also tell of the courageous frankness of "Polo, assessor of the privy council," in opening Kublai's eyes to the iniquities of his agent.

To sum up, we can hardly doubt that we have, imbedded in the text of this most interesting edition of Ramusio's, the supplementary recollections of the traveller, noted down at a later period of his life, but perplexed by translation and retranslation and editorial mistakes. The most important desideratum still remaining in reference to Polo's book is the recovery of the original from which Ramusio derived the passages peculiar to his edition.

That Marco Polo has been so universally recognized as the prince of mediæval travellers is due rather to the width of his experience, the vast compass of his journeys, and the romantic nature of his personal history than to transcendent superiority of character or capacity. Enthusiastic biographers, beginning with Ramusio, have placed him on the same platform with Columbus. But he has left no trace of the genius and lofty enthusiasm, the ardent and

justified previsions, which mark the great admiral as one of the lights of the human race. It is a juster praise that the spur which his book eventually gave to geographical studies, and the beacons which it hung out at the eastern extremities of the earth, helped to guide the aims, though hardly to kindle the fire of the greater son of the rival republic. His work was at least a link in the providential chain which at last dragged the New World to light.

But Polo also was the first traveller to trace a route across the whole longitude of Asia, naming and describing kingdom after kingdom, which he had seen with his own eyes; the first to speak of the new and brilliant court which had been established at Peking; the first to reveal China in all its wealth and vastness, and to tell us of the nations on its borders, with all their eccentricities of manners and worship; the first to tell more of Tibet than its name, to speak of Burmah, of Laos, of Siam, of Cochinchina, of Japan, of Java, of Sumatra, and of other islands of the Great Archipelago, that museum of beauty and marvels, of Nicobar and Andaman Islands with their naked savages, of Ceylon and its sacred peak, of India, not as a dream-land of fables, but as a country seen and partially explored; the first in mediæval times to give any distinct account of the secluded Christian empire of Abyssinia, and of the semi-Christian island of Socotra, and to speak, however dimly, of Zanzibar, and of the vast and distant Madagascar; whilst he carries us also to the remotely opposite region of Siberia and the Arctic shores, to speak of dog-sledges, white bears, and reindeer-riding Tunguses. That all this rich catalogue of discoveries (as they may fitly be called) should belong to the revelation of one man and one book is ample ground enough to justify a very high place in the roll of fame.

Indeed it is remarkable in how large a proportion of the Old World modern travellers and explorers have been but developing what Marco Polo indicated in outline,—it might be said, without serious hyperbole, only travelling in his footsteps, most certainly illustrating his geographical notices. At the moment when these lines are written a British mission is starting to survey for political reasons a tract upon the Oxus; Marco Polo traversed this tract. For twenty years Russian and English explorers have been trying to solve the problem of the Pamir watershed; Marco Polo explored it. Till within the last quarter century the cities of eastern Turkestan, such as Kashgar, Yarkand, and Khotan, were known only from the compilation of Oriental fragments; Marco had visited them all. Within a shorter period dense darkness hung over the tracts between western China and Upper Burmah; these also had been traversed by Marco Polo. Franco is now scattering the brands of war in Tong-king, in Fuhkien, and in Madagascar; all these were within Marco Polo's knowledge and find mention in his book. And how vast an area has he described from personal knowledge which remains outside of the fields that we have indicated! Readers of the book would welcome a little more of egotistical detail. Impersonality is carried to excess; and we are often driven to discern only by indirect and doubtful induction whether he is speaking of places from personal knowledge or from hearsay. In truth, though there are delightful exceptions, and though nearly every part of the book suggests interesting questions, a desperate meagreness and baldness does affect considerable parts of the narrative. In fact his work reminds us sometimes of his own description of Khorasan—"On chevauche par beaux plains et belles costieres, là ou il a moult beaus herbages et bonne pasture et frais assez . . . et aucune fois y treuve l'en un desert de soixante milles ou do mains, esquel desers ne treuve l'en point d'eau; mais la convient porter o lui!"

The diffusion of the book was hardly so rapid as has been sometimes alleged. It is true that we know from Gilles Mallet's catalogue of the books collected in the Louvre by Charles V., dating c. 1370-75, that no less than five copies of Marco Polo's work were then in the collection; but on the other hand the number spread over Europe of MSS. and early printed editions of Mandeville, with his lying vendors, indicates a much greater popularity. Dante, who lived twenty-three years after the book was dictated, and who touches so many things in the seen and unseen worlds, never alludes to Polo, nor, we believe, to anything that can be connected with him; nor can any trace of Polo be discovered in the book of his contemporary Marino Sanudo the elder, though this worthy is well acquainted with the work, later by some years, of Hayton the Armenian, and though many of the subjects on which he writes in his own book (*De Secretis Fidei et Crucis*<sup>1</sup>) challenge a reference to Polo's experiences. Perhaps indeed the most notable circumstance bearing in the same direction is the fact that the author of Mandeville, whoever he really was, and who plundered right and left, never plunders Polo, a thing only to be accounted for by his being ignorant of Polo's existence. The only literary work we know of belonging to the 14th century which shows a thorough acquaintance with Polo's book is the poetical romance of *Baudouin de Sebourg*, which borrows themes from it largely.

Marco Polo contributed so vast an amount of new facts to the knowledge of the earth's surface, that one might have expected his

<sup>1</sup> Printed by Bongars in the collection called *Gesta Dei per Francos*, 1611.

book to have a sudden effect upon geography. But no such result occurred for a long time. Doubtless several causes contributed to this, of which the unreal character attributed to the book as a collection of romantic marvels, rather than of geographical and historical facts, may have been one,—a view that the diffusion of Mandeville's fictions, far outdoing Polo's facts in marvel, perhaps tended to corroborate, whilst supplanting the latter in popularity. But the essential causes were the imperfect nature of publication; the traditional character of the prevailing geography, which hampered the propagation of true statements; and the entire absence of scientific principle in what did pass for geography, so that there was no organ competent to the assimilation of so huge a mass of new knowledge.

The late Sir Francis Palgrave wrote a book called *The Merchant and the Friar*, in which it is feigned that Marco Polo comes to England, and becomes acquainted with Roger Bacon. Had Roger Bacon indeed known either the traveller or his book, we cannot doubt, from the good use he makes, in his *Opus Majus*, of William of Rubruk, that he would have turned the facts to good account.

But the world with which the map makers of the 13th and 14th centuries dealt was, in its outline, that handed down by traditions of the craft, as sanctioned by some fathers of the church, such as Orosius and Isidore, and sprinkled with a combination of classical and mediæval legends. Almost universally the earth's surface fills a circular disk, rounded by the ocean,—a fashion that already was ridiculed by Herodotus (iv. 36), as it was in a later generation by Aristotle (*Meteorol.*, ii. 5). This was the most persistent and the most obstructive dogma of the false geography. The central point of the circle is occupied by Jerusalem, because it was found written in Ezekiel:—"Hæc dicit Dominus Deus, Ista est Jerusalem, in medio gentium posui eam, et in circuitu ejus terras,"—supposed to be corroborated by the Psalmist's expression, regarded as prophetic of our Lord's passion—"Deus autem Rex noster ante sæcula operatus est salutem in medio terræ" (Ps. lxxiv. 12). Paradise occupied the extreme east, because it was found in Genesis that the Lord planted a garden eastward in Eden. Gog and Magog were set in the far north or north-east because it was again said in Ezekiel; "Ecce ago super te Gog principem capitis Mosoch et Thihai . . . et ascendere te faciam de lateribus aquilonis." This last legend of Gog and Magog, shunt up by a mountain-barrier, plays a prominent part in the romantic history of Alexander, which had such enormous currency in those ages, and attracted especial attention in the 13th century, owing to the general identification of the Tartar hordes with those impure nations whom the hero had shunt up. It is not wonderful that the Tartar irruption into the West, heard of at first with as much astonishment as it would produce now, was connected with this old belief.

The loose and scanty nomenclature of the cosmography was mainly borrowed from Pliny and Mela, through such fathers as we have named; whilst vacant spaces were occupied by Amazons, Arimaspians, and the realm of Prester John. A favourite representation of the inhabited earth was a great T within an O (see MAP).

Such schemes of the world had no place for the new knowledge. The first genuine attempt at a geographical compilation absolutely free from the traditional *idola* seems to be that in the *Portulano Mediceo* at Florence. In this, some slight use seems to be made of Polo. But a far more important work is one of the next generation, the celebrated Catalan map of 1375 in the Paris library. This also is an honest endeavour on a large scale to represent the known world on the basis of collected facts, casting aside all theories, pseudo-scientific and pseudo-theological; and a very remarkable work it is. In this work Marco Polo's influence on maps is perhaps seen to the greatest advantage. As regards Central and Farther Asia, and partially as regards India, his book is the basis of the map. His names are often much perverted, and it is not always easy to understand the view that the compiler took of his itineraries. Still we have Cathay admirably placed in the true position of China, as a great empire filling the south-east of Asia. The trans-Gangetic peninsula is absent, but that of India proper is, for the first time in the history of geography, represented with a fair approximation to correct form and position. We really seem to see in this map something like the idea of Asia that the traveller himself would have presented, had he bequeathed us a map.

In the following age we find more frequent indications that Polo's book was diffused and read. And now that the spirit of discovery was beginning to stir, the work was regarded in a juster light as a book of facts, and not as a mere *Roman du Grant Kaan*. But the age produced new supplies of information in greater abundance than the knowledge of geographers was prepared to digest or co-ordinate; and, owing partly to this, and partly to his unhappy reversion to the fancy of a circular disk, the map of Fra Mauro (1459), one of the greatest map-making enterprises in history, and the result of immense labour in the collection of facts and the endeavour to combine them, really gives a much less accurate idea of Asia than the *Carta Catalana*.

When M. Libri, in his *Hist. des Sciences Mathématiques*, speaks of Columbus as "jealous of Polo's laurels," he speaks rashly. In fact

Columbus knew of Polo's revelations only at second-hand, from the letters of the Florentine Paolo Toscanelli and the like; we cannot find that he ever refers to Polo by name. Though, to the day of his death, Columbus was full of imaginations about Zipangu (Japan) and the land of the Great Khan, as being in immediate proximity to his discoveries, these were but accidents of his great theory. It was his intimate conviction of the absolute smallness of the earth, of the vast extension of Asia eastward, and of the consequent narrowness of the western ocean on which his life's project was based.

When, soon after the discovery of the New World, attempts were made to combine the new and old knowledge, the results were unhappy. The earliest of such combinations tried to realize the ideas of Columbus regarding the identity of his discoveries with the Great Khan's dominions; but even after America had vindicated its independent existence, and the new knowledge of the Portuguese had introduced China where the Catalan map had presented Cathay, the latter country, with the whole of Polo's nomenclature, was shunted to the north, forming a separate system. Henceforward the influence of Polo's work on maps was simply injurious; and when to his names was added a sprinkling of Ptolemy's, as was usual throughout the 16th century, the result was a hotch-potch conveying no approximation to any representation of facts.

Gradually the contributions of Ptolemy and Polo are used more sparingly, but in Sanson's map (1659) a new element of confusion appears in numerous features derived from the "Nubian Geographer," i.e., Edrisi.

It is needless to follow the matter further. With the increased knowledge of northern Asia from the Russian side, and of China from the maps of Martini, followed by the later Jesuit surveys, and with the real science brought to bear on Asiatic geography by such men as De l'Isle and D'Anville, mere traditional nomenclature gradually disappeared; and the task which Polo has provided for the geographers of later days has been chiefly that of determining the true localities which his book describes under obsolete or corrupted names.

Before concluding, a word or two seems necessary on the subject of the alleged introduction of important inventions into Europe by Marco Polo. Assertions or surmises of this kind have been made in regard to the mariner's compass, to gunpowder, and to printing. Though the old assertions as to the first two are still occasionally repeated in books of popular character, no one who has paid any attention to the subject now believes Marco can have had anything to do with their introduction. But there is no doubt that the resemblance of early European block-books to those of China is in some respects so striking that it seems clearly to indicate the derivation of the art from that country. There is, however, not the slightest reason for connecting this introduction with the name of Polo. His fame has so overshadowed later travellers that the fact has been generally overlooked that for some years in the 14th century not only were missions of the Roman church established in the chief cities of eastern China, but a regular overland trade was carried on between Italy and China, by way of Tana (Azoff), Astrakhan, Otrar, Kamul (Hami), and Kan-chow. Many a traveller other than Marco Polo might have brought home the block-books, and some might have witnessed the process of making them. This is the less to be ascribed to Polo, because he so curiously omits to speak of the process of printing, when, in describing the block-printed paper-money of China, his subject seems absolutely to challenge a description of the art. (H. Y.)

POLOTSK, a district town of the government of Vitebsk, at the confluence of the Polota with the Dwina (Düna), 5 miles from the Smolensk and Riga Railway, is one of the oldest towns of Russia. The continuous wars, however, of which, owing to its position on the line of communication between central Russia and the west, it was for many centuries the scene, have allowed almost nothing of its remarkable antiquities to remain. The "upper castle" which stood at the confluence of the rivers and had a stone-wall with seven towers, is now in ruins, as also is the "lower castle," formerly enclosed with strong walls and connected with the upper by a bridge. The numerous monasteries and convents also have disappeared. The cathedral of St Sophia in the upper castle, built in the 12th century, and successively used as a place of worship by the Greek, the Catholic, and the "United" Churches, fell to ruins in the 18th century, when the "United" bishop Grebnicki substituted a modern structure. The town is now of trifling importance, and the population (12,200 in 1880, against 13,800 in 1865) is decreasing. Upwards of two-thirds of the inhabitants are Jews; the remainder have belonged mostly to the Greek Church since

1839, when they were compelled to abandon the Union. Flax, linseed, corn, and timber are the leading articles of the commerce of the town.

Polotesk or Poltesk is mentioned in 862 as one of the towns given by Rurik to his men, together with Byelo-ozero and Rostoff. In 980 it had a prince of its own, Rogvolod, whose daughter is the subject of many legends. It remained an independent principality until the 12th century, resisting the repeated attacks of the princes of Kieff; those of Pskoff, Lithuania, and the Livonian knights, however, proved more powerful, and it fell under Lithuanian rule in the following century. About 1385 its independence was destroyed by the Lithuanian prince Witowt. It was five times besieged by Moscow in 1500-18, and was taken by John the Terrible in 1563. Recaptured by Stephen Batory sixteen years later, it became Polish by the treaty of 1582. It was then a populous city, which, enjoying the privileges of "Magdeburg law" from 1498, carried on an active commerce, and covered a large area. Pestilences and conflagrations were its ruin; the plague of 1566 wrought great havoc among its inhabitants, and that of 1600 destroyed 15,000. The castles, the town, and its walls were burned in 1607 and 1642. The Russians continued their attacks, burning and plundering the town, and twice taking possession of it for a few years, in 1633 and 1705. It was not definitively annexed, however, to Russia until 1772, after the first dismemberment of Poland. In 1812 its inhabitants resisted the French invasion, and the town was partially destroyed.

POLTAVA, a government of south-western Russia, bounded by Tchernigoff on the N., Kharkoff on the E., Ekaterinoslaff and Kherson on the S., and Kieff on the W., and having an area of 19,265 square miles. Its surface is an undulating plain from 500 to 600 feet above sea-level, with a few elevations reaching 670 feet in the north, and gently sloping to the south-west, where its range is between 300 and 400 feet. Owing to the excavations of the rivers, their banks, especially those on the right, have the aspect of hilly tracts, while low plains stretch to the left. Low-lying districts with some marshes and sandy tracts are met with in the broad valley of the Dnieper, which skirts the province on the south-west. Almost the whole of the surface is covered with Tertiary deposits; chalk appears in the north-east, at the bottom of deeper ravines. The government touches the granitic region of the Dnieper only in the south, below Kremenchug. Limestone with dolerite veins occurs in the isolated hill of Isatchek, which rises above the marshes of the Sula. The whole is covered with a layer, 20 to 60 feet thick, of boulder clay, which, again, is often covered with a thick sheet of loess. Sandstone (sometimes suitable for grindstones) and limestone are quarried, and a few layers of gypsum and peat bog are also known within the government. The soil is on the whole very fertile, with the exception of some sandy tracts. Poltava is watered by the numerous tributaries of the Dnieper, which flows along its border, navigable throughout. Deep sand beds intersected with numberless ravines and old arms of the river stretch along the left bank, where accordingly the settlements are but few. It is joined by the Sula, the Psiol, the Vorskla, the Orel, the Trubezh, and several other tributaries, none of them navigable, although their courses vary from 150 to 270 miles in length. Even those which used to be navigated within the historical period, such as Trubezh and Supoy, are now drying up, while the others are being partially transformed into marshes. Only 5 per cent. of the total area is under wood; timber, wooden wares, and pitch are imported.

The population in 1881 reached 2,418,870, of whom 217,800 lived in towns. The great majority are Little Russians, there being only 20,000 Great Russians, less than 1000 White Russians, some 2000 Poles, and 1500 Germans. In 1865 the Jews were estimated at 40,000. Agriculture is the chief pursuit, there being 7,451,000 acres (60 per cent. of the total area) of arable land, and the average yield of the years 1870-77 being 6,302,000 quarters of corn and 703,200 quarters of potatoes. The crops chiefly grown are wheat, rye, and oats; the sunflower is largely cultivated, especially for oil, and the culture of tobacco, always important, has recently made a very great advance, now yielding about

200,000 cwts. Kitchen gardening, the culture of the plum, and the preparation of preserved fruits are also important branches of industry. At Lubny, where an apothecaries' garden is maintained by the crown, the collection and cultivation of medicinal plants is also a specialty. The main source of wealth in Poltava always has been, and still is, its cattle-breeding. In 1881 there were 209,000 horses, 882,000 cattle, 1,820,000 sheep (only 520,000 of these, as against 878,000 in 1862, being of finer breeds), 405,000 pigs, and 7000 goats. Black and grey sheepskins are largely exported, as also is wool. Some of the wealthier landowners and many peasants now rear finer breeds of horses.

The aggregate value of the manufactures in 1879 was £1,112,100, employing in their production 3755 hands; distilleries hold the leading place (£717,500), after which come flour mills (£136,600), tobacco works (£79,700), machine-making (£35,700), tanneries (£27,700), saw-mills (£20,000), and sugar-works (£10,900). Wool is exported in a raw state, and the woollen manufactures amounted only to £5750. In the villages and towns several domestic trades are carried on, such as the preparation of sheepskins, plain woollen cloth, leather, boots, and pottery.

The fair of Poltava is of great importance for the whole woollen trade of Russia; leather, cattle, horses, coarse woollen cloth, skins, and various domestic wares are also exchanged for manufactures imported from Great Russia. The value of merchandise brought to the fair reaches and sometimes exceeds 25,000,000 roubles. Several other fairs, the aggregate returns for which reach more than one-half of the above, are held at Romny (tobacco), Kremenchug (timber, corn, tallow, and salt), and Kobelyaki (sheepskins). Corn is exported to a considerable extent to the west and to Odessa, as also saltpetre, spirits of wine, wool, tallow, skins, and plain woollen cloth. The navigation on the Dnieper is interfered with by want of water, and becomes active only in the south. The chief traffic is by railway.

The government is divided into fifteen districts, the chief towns of which are—Poltava (41,050 inhabitants), Gadyatch (9250), Khorol (5175), Kobelyaki (13,150), Konstantinograd (4320), Kremenchug (46,620 with Krukoff), Lokhvitsa (9320), Lubny (9820), Mirgorod (7750), Pereyaslaff (13,350), Piryatin (5400), Priluki (13,100), Romny (12,310), Zolotonosha (7180), and Zyenkoff (8360). Glinsk (3250) and Gradijsk (7850) have also municipal institutions, while several villages and towns (Sorotchintsy, Borispol, Smyeloye, Grun, Ryeshetilovka, &c.) have from 6500 to 8000 inhabitants.

*History.*—At the dawn of Russian history the region now occupied by Poltava was inhabited by the Syeveryanes. As early as 988 the Russians erected several towns on the Sula and Trubezh for their protection against the Petchenegs and Polovtsy, who held the south-eastern steppes. Population extended, and the towns Pereyaslaff, Lubny, Lukomy, Priluki, Piryatin, Romny, &c., begin to be mentioned in the 11th and 12th centuries. The Mongol invasion destroyed most of them, and for two centuries afterwards they totally disappear from Russian annals. About 1231 Gedimin annexed the so-called "Syeverisk towns" to Lithuania, and on the recognition of the union of Lithuania with Poland they were included in the united kingdom along with the remainder of Little Russia. In 1476 a separate principality of Kieff under Polish rule and Polish institutions was formed out of Little Russia, and remained so until the rising of Bogdan Khmelnytskii in 1654. By the Andrusoff treaty, the left bank of the Dnieper being ceded to Russia, Poltava became part of the dominions of the Zaporogian hetman, and was divided into "regiments," six of which (Poltava, Pereyaslaff, Priluki, Gadyatch, Lubny, and Mirgorod) lay within the limits of the present government. They lost their independence in 1764, and serfdom was introduced in 1783, the Poltava region becoming part of the governments of Kieff and Ekaterinoslaff. The present government was instituted in 1802.

POLTAVA, capital of the above government, stands on the right bank of the Vorskla, 88 miles by rail to the west-south-west of Kharkoff. The town is built on a plateau which descends by steep slopes nearly on all sides; the buildings are separated by large yards and gardens. Several suburbs, inhabited by Cossacks, whose houses are buried amid gardens, and a German colony, surround the town. Water is scarce, and has to be brought a long distance, from the marshy Vorskla. The oldest buildings are the Krestovozdvijenskiy monastery, erected in 1650, and a wooden church visited by Peter I. after the battle of Poltava. There are two lyceums for boys and girls, a "realschule," a military school for cadets, a theological seminary, and two girls' colleges, besides Russian, German, and Jewish primary schools. The manufactures are insignificant (£58,000 in 1879); the principal are tobacco works (£27,500) and a

tannery (£14,499). The trade derives its importance from the four fairs that are held at Poltava. The chief of these, in July (noted above), is visited by 30,000 to 40,000 people. In 1881 the population was 41,959.

Poltava is mentioned in Russian annals in 1374, under the name of Lova, but does not again appear in history until 1647, when, together with Glukh, it was given by Gedymin to the Tartar prince Leisak. Under Bogdan Khmelnytsky it was the chief town of the Poltava "regiment." Peter I. defeated Charles XII. in the immediate neighbourhood on June 27, 1709.

**POLYANUS**, a Macedonian, lived at Rome as a rhetorician and pleader in the 2d century. When the Partian War (162-165 A.D.) broke out, Polyanus, too old to share in the campaign, dedicated to the emperors Marcus Antoninus and Lucius Verus a work, still extant, called *Strategion* or *Strategemata*, an historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes. It is not strictly confined to warlike stratagems, but includes also examples of wisdom, courage, and cunning drawn from civil and political life. The work is uncritically and negligently written, but is nevertheless important on account of the extracts it has preserved from histories now lost. It is divided into eight books, and originally contained nine hundred anecdotes, of which eight hundred and thirty-three are extant. Polyanus intended to write a history of the Partian War, but there is no evidence that he did so. His works on Macedonia, on Thracia, and on tactics (if indeed this be not identical with the *Strategion*) are lost.

His *Strategion* seems to have been highly esteemed by the Roman emperors and so have been handed down by them as a sort of textbook. From Rome it passed to Constantinople; at the end of the 9th century it was diligently studied by Leo VI., who himself wrote a work on tactics; and in the middle of the 10th century Constantine Porphyrogenitus mentioned it as one of the most valuable books in the imperial library. It was used by Suidas, Scylitzes, and the anonymous author of the work *repl. de l'art de la guerre* (*Mythographi Græci*, ed. Westermann, p. 225). It is mentioned as follows:—*lib. i.*, *lib. ii.*, *lib. iii.*, stratagems concerning in Greek history, from the mythical times of Demeter and Hermes down to the Macedonian kings and successors of Alexander the Great; *lib. iv.*, stratagems concerning in the history of Italy and the Greek islands and colonies; *lib. v.*, stratagems of whole peoples (Carthaginians, Locustians, Angles, &c.); together with some of individuals (Philopomen, Pyrrhus, Hannibal, &c.); *lib. vi.*, stratagems of the barbarians (Scythians, Persians, Egyptians, Thracians, Syrians, Celts); *lib. vii.*, stratagems of Romans and Roman. This division is not, however, observed very strictly. Of the negligence or haste with which the work was written there are many instances: e.g., he confounds Diogenes the elder and Diogenes the younger, Minutius sumus of Ambracia and Minutius the Great, Scipio the elder and Scipio the younger; he mixes up the stratagems of Caesar and Pompey; he brings two immediate occasions events which were widely distant; he repeats some events twice over, with variations according to the different sources from whom he drew. Though he usually abridges, he occasionally amplifies, especially the narratives of his authorities. He never mentions his authorities, but amongst authorities must be used Herodotus, Thucydides, Demosthenes, Polybius, Diodorus, Plutarch, Strabo, and Suetonius; amongst authors of whom only fragments now remain he drew upon Cæsar, Epictetus, Titianus, Polyarchus, and perhaps Aristarchus, Dionysius, Herodotus, Megasthenes, and Nicæus of Damascus. His style is clear, but unpolished and inelegant. He keeps up parallelisms and falls alternately into the opposite faults of accumulating and totally omitting circumstances. A glaring instance of these faults is to be found in *lib. iii.* 9, 12. In the form of his words he generally follows Attic usage.

His work was first printed in a Latin translation by Joann. Tacticus (Basel, 1545); the Greek text was first edited by Casaubon (Leyden, 1637), but mainly from a very defective MS. Reuss in his edition (Götting, 1834), corrected the text in many places. The best edition is that of Müller (Leipzig, 1867), whose preface may be consulted with advantage.

**POLYANTHUS**. See **PARVOSUS**.

**POLIBIUS**, the historian, was a native of Megalopolis in Arcadia, the youngest of Greek cities (Paus. viii. 9), but one which played an honourable part in the last days of Greek freedom as a staunch member of the Achaean league. Polybius's father Lycortas was the intimate friend of Philopomen, himself also a citizen of Megalopolis, and on the death of the latter, in 182 B.C.,

succeeded him as leader of the league. The date of Polybius's birth can only be fixed approximately. He tells us himself that in 181 he had not yet reached the age of 30 years, *Polib., xix.* 9, at which an Achaean was legally capable of holding office (*xix.* 6). We learn from Cicero (*Ad Fam.* v. 12) that he entered the Numantine war, which ended in 132, and from Lucian (*Moroch.* 22) that he died at the age of eighty-two. We may therefore follow the majority of authorities in placing his birth between 214 and 204 B.C. Little is known of his early life. As the son of Lycortas he was naturally brought into close contact with the leading men of the Achaean league. With the foremost of them, Philopomen, he seems to have been on intimate terms. Plutarch (*de exor.* 12) describes him as sitting at the feet of the great Achaean soldier, of whom Polybius himself always writes in terms of affectionate admiration; and after Philopomen's tragic death in Messenia (182) he was entrusted with the honourable duty of conveying home the urn in which his ashes had been deposited (*Plut., Phil.* 21). The next year (181) witnessed what seems to have been his first entry into political life. Together with his father Lycortas and the younger Aratus, he was appointed, in spite of his youth, a member of the embassy which was to visit Ptolemy Epiphanes, king of Egypt—a mission, however, which the sudden death of Ptolemy brought to a premature end (*xix.* 7). The next twelve years of his life are a blank, but in 169 he reappears as a trusted adviser of the Achæans at a difficult crisis in the history of the league. In 171 war had broken out between Rome and the Macedonian king Perseus, and the Achaean statesmen were divided as to the policy to be pursued: to side with Macedonia would have been suicidal; Lycortas himself was in favour of neutrality, but there were good reasons for fearing that the Roman senate would regard neutrality as indicating a secret leaning towards Macedonia, and indeed both Lycortas and Polybius himself had already incurred suspicion at Rome on this ground. Polybius therefore declared for an open alliance with Rome, and his views were adopted. It was decided to send an Achaean force to cooperate with the Roman general. Polybius was selected to command the cavalry, and was at once despatched to the Roman camp to announce the decision of the league (*xviii.* 10-12). The Roman consul declined the proffered assistance, but Polybius accompanied him throughout the campaign, and thus gained his first insight into the military system of Rome. On his return home he was able to render an important service to his countrymen by checking the unauthorized attempt of a Roman officer to raise troops in Achaia (*xviii.* 13). In the next year (168) both Lycortas and Polybius were on the point of starting at the head of 1200 Achæans to take service in Egypt against the Syrians, when an intimation from the Roman commander that armed interference was undesirable put a stop to the expedition (*xix.* 23). The success of Rome in the war with Perseus was now assured, and it is possible that the readiness of Lycortas and Polybius to serve abroad was partly due to a belief that the fate of Macedonia must soon be shared by Achaia. If this was so, the belief was but too well founded. The final defeat of Perseus was rapidly followed by the arrival in Achaia of Roman commissioners charged with the duty of securely establishing Roman interests there. As a result of their proceedings 1000 of the principal Achæans were arrested and carried off to Italy. Polybius was among the number, but, while his companions were condemned to a tedious incarceration in the country towns of Italy, he obtained permission to reside in Rome. This privilege he owed to the influence of *Antius* Paulus, and his two sons

Scipio and Fabius (xxxii. 9), who seem to have made his acquaintance in Macedonia. At any rate Polybius was received into Æmilius's house, and became the instructor of his sons (Appian, *Pun.*, 132). Between Scipio, the future conqueror of Carthage, and himself a friendship soon sprung up which ripened into a lifelong intimacy. To the last Scipio so constantly relied upon the advice and counsel of Polybius that it could be said by the countrymen of the latter that Scipio never failed when he followed the advice of his friend (Pausan., viii. 30). To Polybius himself his friendship with Scipio was not merely the chief pleasure of his life but of inestimable service to him throughout his career. It protected him from interference, opened to him the highest circles of Roman society, and enabled him to acquire a personal influence with the leading men, which stood him in good stead when he afterwards came forward to mediate between his countrymen and Rome. It placed within his reach opportunities for a close study of Rome and the Romans such as had fallen to no historian before him, and secured him the requisite leisure for using them, while Scipio's liberality more than once supplied him with the means of conducting difficult and costly historical investigations (Pliny, *N. H.*, v. 9). In 151, after seventeen years of banishment, the few surviving exiles were allowed to return to Greece. But the stay of Polybius in Achaia was brief. The estimation in which he was held at Rome is clearly shown by the anxiety of the consul Mamilius (149) to take him as his adviser on his expedition against Carthage. Polybius started to join him, but broke off his journey at Coreyra on learning that the Carthaginians were inclined to yield and that war was unlikely (xxxvi. 3). But when, in 147, Scipio himself took the command in Africa, Polybius hastened to join him, and was an eye-witness of the siege and destruction of Carthage (Appian, *Pun.*, 132). During his absence in Africa, the Achæans had made a desperate and ill-advised attempt to assert for the last time their independence of Rome,—a passionate outbreak which Polybius had dreaded, and which his presence might have prevented. As it was he returned in 146 to find Corinth in ruins, the fairest cities of Achaia at the mercy of the Roman soldiery, and the famous Achæan league shattered to pieces (Pol. ap. Strabo, p. 381). But there was still work to be done that he alone could do. All the influence he possessed was freely spent in endeavouring to shield his countrymen from the worst consequences of their rashness. The excesses of the soldiery were checked, and at his special intercession the statues of Aratus and Philopœmen were preserved (xxxix. 14). An even more difficult task was that entrusted to him by the Roman authorities themselves, of persuading the Achæans to acquiesce in the new régime imposed upon them by their conquerors, and of setting the new machinery in working order. With this work, which he accomplished so as to earn the heartfelt gratitude of his countrymen (xxxix. 16), his public career seems to have closed. The rest of his life was, so far as we know, devoted to the great history which is the lasting monument of his fame. He died at the age of eighty-two of a fall from his horse (Lucian, *Macrob.*, 22).

Of the forty books which made up the history of Polybius, the first five alone have come down to us in a complete form; of the rest we have only more or less copious fragments. But as to the general plan and scope of the work there is no room for doubt, thanks mainly to the clearness with which they are explained by Polybius himself. The task which he set himself was that of making plain, for the instruction of his own and future generations, how and why it was that "all the known regions of the civilized world had fallen under the sway of Rome" (iii. 1). This empire of Rome, unprecedented in its extent and still more so in the rapidity with which it had been acquired, was the standing wonder of the age, and "who," he exclaims (i. 1), "is so poor-spirited or indolent

as not to wish to know by what means, and thanks to what sort of constitution, the Romans subdued the world in something less than fifty-three years?" These fifty-three years are those between 220 (the point at which the work of Aratus ended) and 168 B.C., and extend therefore from the outbreak of the Hannibalic war to the defeat of Perseus at Pydna. To this period then the main portion of his history is devoted from the third to the thirtieth book inclusive. But for clearness' sake he prefixes in books i. and ii. such a preliminary sketch of the earlier history of Rome, of the first Punic War, and of the contemporary events in Greece and Asia, as will enable his readers more fully to understand what follows. This seems to have been his original plan, but at the opening of book iii., written apparently after 146, he explains that he thought it desirable to add some account of the manner in which the Romans exercised the power they had won, of their temperament and policy, and of the final catastrophe which destroyed Carthage and for ever broke up the Achæan league (iii. 4, 5). To this appendix, giving the history from 168–146, the last ten books are devoted.

Whatever fault may be found with Polybius, there can be no question that he had formed a high conception of the task before him, and of the manner in which it should be executed. He lays repeated stress on two qualities as distinguishing his history from the ordinary run of historical compositions. The first of these, its synoptic character, was partly necessitated by the nature of the period with which he was dealing. The interests, fortunes, and doings of all the various states fringing the basin of the Mediterranean had become so inextricably interwoven that it was no longer possible to deal with each of them in isolation. The historian must deal with this complex web of affairs as a whole, if he would be able either to understand or to explain it properly. Polybius therefore claims for his history that it will take a comprehensive view of the whole course of events in the civilized world, within the limits of the period with which it deals (i. 4). In doing so he marks a new point of departure in historical writing, "for we have undertaken" he says "to record, not the affairs of this or that people, like those who have preceded us, but all the affairs of the known world at a certain time." In other words, he aims at placing before his readers at each stage a complete survey of the field of action from Spain in the West to Syria and Egypt in the East. This synoptic method proceeds from a true appreciation of what is now called the unity of history, and to Polybius must be given the credit of having first firmly grasped and clearly enforced a lesson which the events of his own time were especially well calculated to teach. Posterity too has every reason to be grateful, for, though, as will be seen later, this synoptic method frequently interferes with the symmetry and continuity of his narrative, yet it has given us such a picture of the 2d and 3d centuries before Christ as no series of special narratives could have supplied.

The second quality upon which Polybius insists as distinguishing his history from all others is its "pragmatic" character. It deals, that is, with events and with their causes, and aims at an accurate record and explanation of ascertained facts. This "pragmatic method" (ix. 2) has a double value. First of all it makes history intelligible by explaining the how and the why; and, secondly, it is only when so written that history can perform its true function of instructing and guiding those who study it. For the great use of history according to Polybius is to contribute to the right conduct of human life (i. 35), by supplying a storehouse of experience for the assistance of those who will use it. But this it can only do if the historian bears in mind the true nature of his task. Above all things he must not content himself with merely writing a pleasant tale. He must remember that the historian should not write as the dramatist does to charm or excite his audience for the moment but to edify and instruct all serious students in the future (ii. 56). He will therefore aim simply at exhibiting events in their true light, setting forth "the why and the how" in each case, not confusing causes and occasions, or dragging in old wives' fables, prodigies, and marvels (ii. 16; iii. 48). He will omit nothing which can help to explain the events he is dealing with: the genius and temperament of particular peoples, their political and military systems, the characters of the leading men, the geographical features of the country, must all be taken into account. To this conception of the aim and methods of history Polybius is on the whole consistently faithful in practice. It is true that his anxiety to instruct leads often to a rather wearisome iteration of his favourite maxims, and that his digressions, such as that on the military art, are occasionally provokingly long and didactic. But his comments and reflexions are for the most part sound and instructive (e.g., those on the lessons to be learnt from the revolt of the mercenaries in Africa, i. 65; from the Celtic raids in Italy, ii. 35; and on the Roman character), while among his digressions are included such invaluable chapters as those on the Roman constitution (book vi.), the graphic description of Cisalpine Gaul (book ii.), and the account of the rise and constitution of the Achæan league (ii. 38 sq.). To his anxiety again to trace back events to their first causes we owe, not only the careful inquiry (book iii.) into the origin of the

Second Punic War, but the sketch of early Roman history in book i., and of the early treaties between Rome and Carthage in iii. 22 sq. Among the many defects which he censures in previous historians, not the least serious in his eyes are their inattention to the political and geographical surroundings of the history (ii. 16; iii. 36), and their neglect duly to set forth the causes of events (iii. 6).

Polybius is equally explicit as regards the personal qualifications necessary for a good historian, and in this respect too his practice is in close agreement with his theory. He has a profound distrust of closet students and a profound belief in the value of a personal knowledge of affairs. Without such experience a writer will, he says, be guilty of endless blunders and omissions, and will inevitably distort the true relations and importance of events. History, he asserts, will not be satisfactorily written until either men of affairs undertake to write it, not as a piece of bye-work but as an honourable and necessary task, or until intending historians realize that some actual experience of affairs is indispensable (xii. 28). Such experience would have saved accomplished and fluent Greek writers like Timæus from many of their blunders (xii. 25a), but the shortcomings of Roman soldiers and senators like Q. Fabius Pictor show that it is not enough by itself. Equally indispensable is careful painstaking research. All available evidence must be collected, thoroughly sifted, soberly weighed, and, lastly, the historian must be animated by a sincere love of truth and a calm impartiality. What follows where any or all of these conditions and qualifications are absent Polybius illustrates abundantly in his frequent and scathing criticisms on previous writers. In the case of Timæus, against whom he seems to cherish a peculiar animosity, nearly all that remains of book xii. is devoted to an exposition of his shortcomings. Q. Fabius Pictor and Philinus are charged both with ignorance of important facts and with partiality (i. 14; iii. 9), while in the second book Phylarchus's account of the war between the Achaean league and Cleomenes of Sparta is mercilessly dissected.

It is not possible here to discuss the question whether Polybius has been just to his predecessors; it is more important to consider how far he himself comes up to the standard by which he has tried others. In his personal acquaintance with affairs, in the variety of his experience, and in his opportunities for forming a correct judgment on events he is without a rival among ancient historians. A great part of the period of which he treats fell within his own lifetime (iv. 2). He may just have remembered the battle of Cynoscephalae (197). He must have been sixteen or seventeen years old at least when the power of Antiochus was broken at Magnesia (189), while of the events from 163-146 he was, as he tells us (iii. 4), not only an eye-witness but a prominent actor in them all. As the son of Lycortas he lived from his early youth in immediate contact with the foremost statesmen of the Peloponnesus, while between 181 and 163 he was himself actively engaged in the military and political affairs of the Achaean league. The period of his exile in Rome served to add largely to his stores of experience: he was able to study at close quarters the working of the Roman constitution, and the peculiarities of the Roman temperament; he made the acquaintance of Roman senators, and became the intimate friend of the greatest Roman of the day. Lastly, he was able to survey with his own eyes the field on which the great struggle between Rome and Hannibal was fought out. He left Rome only to witness the crowning triumph of Roman arms in Africa, and to gain a practical acquaintance with Roman methods of government by assisting in the settlement of his own beloved Achaia. When, in 146, his public life closed, he completed his preparation of himself for his great work by laborious investigations of archives and monuments, and by a careful personal examination of historical sites and scenes. If to all this we add that he was deeply read in the learning of his day (Elian, *Tact. i.*, ἀνὴρ πολυμαθής), above all in the writings of earlier historians, we must confess that, as at once scholar, statesman, soldier, and man of the world, he was above all others fitted to write the history of the age of transition in which he lived.

Of Polybius's anxiety to get at the truth no better proof can be given than his conscientious investigation of original documents and monuments, and his careful study of geography and topography—both of them points in which his predecessors, as well as his successor Livy, conspicuously failed. Polybius is careful constantly to remind us that he writes for those who are φιλομαθεῖς, lovers of knowledge, with whom truth is the first consideration. He closely studied the bronze tablets in Rome on which were inscribed the early treaties concluded between Romans and Carthaginians (see for these *Rhein. Mus.*, 32, 614; iii. 22-26). He quotes the actual language of the treaty which ended the First Punic War (i. 62), and of that between Hannibal and Philip of Macedon (vii. 9). In xvi. 15 he refers to a document which he had personally inspected in the archives at Rhodes, and in iii. 33 to the monument on the Lacinian promontory, recording the number of Hannibal's forces. According to Dionysius. i. 17, he got his date for the foundation of Rome from a tablet in the pontifical archives. As instances of his careful attention to geography and topography we have not only the fact of his widely extended travels, from the

African coast and the Pillars of Hercules in the west to the Euxine and the coasts of Asia Minor in the east, but also the geographical and topographical studies scattered throughout his history, such as the description of Sicily (i. 42), of Cisalpine Gaul (ii. 14), and of the Euxine (iv. 10), the discussion of Hannibal's route over the Alps, and the graphic picture of the scene of the battle of Lake Trasimene. Lastly, to judge from its extant fragments, book xxxiv. seems to have been actually a treatise on geography in general.

Next to the duty of original research, Polybius ranks that of impartiality. Some amount of bias in favour of one's own country may, he thinks, be pardoned as natural (xvi. 14); but it must not be gratified at the expense of truth. It is unpardonable, he says, for the historian to set anything whatever above the truth. And on the whole Polybius must be allowed here again to have practised what he preached. It is true that his own sympathies and antipathies are not entirely concealed. His affection for and pride in Arcadia appear in more than one passage (iv. 20, 21), as also does his dislike of the Aolians (ii. 45; iv. 3, 16). His treatment of Aratus and Philopomen, the heroes of the Achaean league, and of Cleomenes of Sparta, its most constant enemy, is perhaps open to severer criticism—it is at any rate certain that Cleomenes does not receive full justice at his hands. Similarly his views of Rome and the Romans may have been influenced by his firm belief in the necessity of accepting the Roman supremacy as inevitable, and by his intimacy with Scipio, the head of the great patrician house of the Cornelii. He has evidently a deep admiration for the great republic, for her well-balanced constitution, for her military system, and for the character of her citizens. He shares too the dislike of the Roman aristocracy for such men of the people as Flaminius (ii. 21) and Varro (iii. 116). But, just as his patriotism does not blind him to the faults and follies of his countrymen (xxxviii. 4, 5, 6), so he does not scruple to criticize Rome. He notices the incipient degeneracy of Rome after 146 (xviii. 35). He endeavours to hold the balance evenly between Rome and Carthage; he strongly condemns the Roman occupation of Sardinia as a breach of faith (iii. 28, 31); and he does full justice to the splendid generalship of Hannibal. Moreover, whether his liking for Rome was excessive or not, there can be no doubt that he has sketched the Roman character in a masterly fashion. Their ambition, their invincible confidence in themselves, their dogged courage which made them more dangerous the harder they were pressed, and their devotion to the state are all clearly brought out. Nor does he show less appreciation of their practical sagacity, their readiness to learn from other peoples, their quickness in adapting their tactics both in war and diplomacy to changing circumstances, and their mastery of the art of ruling.

His interest in the study of character and his skill in its delineation are everywhere noticeable. He believes, indeed, in an overruling Fortune, which guides the course of events. It is Fortune which has fashioned anew the face of the world in his own time (iv. 2), which has brought the whole civilized world into subjection to Rome (i. 4); and the Roman empire itself is the most marvellous of her works (viii. 4). But under Fortune not only political and geographical conditions but the characters and temperaments of nations and individuals play their part. Fortune selects the best instruments for her purposes. The Romans had been fitted by their previous struggles for the conquest of the world (i. 63); they were chosen to punish the treachery of Philip of Macedon (xv. 4); and the greatest of them, Scipio himself, Polybius regards as the especial favourite of fortune (xxii. 15; x. 5).

The praise which the matter of Polybius's history deserves cannot be extended to its form, and in this respect he contrasts sharply with Livy, whose consummate skill as a narrator has given him a popularity which has been denied to Polybius. Some of the most serious defects which spoil Polybius's history as a work of art are due to an over-rigid adherence to those views of the nature of the task before him which have been described above. His laudable desire to be comprehensive, and to present a picture of the whole political situation at each important moment, is fatal to the continuity of his narrative. The reader is hurried hither and thither from one part of the field to another in a manner at once wearisome and confusing. Thus the thrilling story of the Second Punic War is broken in upon by digressions on the contemporary affairs in Greece and in Asia. More serious, however, than this excessive love of synchronism is Polybius's almost pedantic anxiety to edify and to instruct. For grace and elegance of composition, and for the artistic presentation of events, he has a hardly concealed contempt. Hence a general and almost studied carelessness of effect, which mars his whole work. On the other hand he is never weary of preaching. His favourite theories of the nature and aims of history, of the distinction between the universal and special histories, of the duties of an historian, sound as most of them are in themselves, are enforced again and again at undue length and with wearisome iteration. No opportunity is lost of pointing out the lesson to be learnt from the events described, and more than once the reader is irritated, and the effect of a graphic picture is spoiled, by obtrusive moralizing. Nor, lastly, is Polybius's style itself such as to compen-

sate for these defects. It is, indeed, often impressive from the evident earnestness and sincerity of the writer, and from his sense of the gravity of his subject, and is unspoiled by rhetoric or conceit. It has about it the ring of reality; the language is sometimes pithy and vigorous; and now and then we meet with apt metaphors, such as those borrowed from boxing (i. 57), from cock-fighting (i. 58), from draughts (i. 84). But, in spite of these redeeming features, the prevailing baldness of Polybius's style excludes him from the first rank among classical writers; and it is impossible to quarrel with the verdict pronounced by Dionysius of Halicarnassus, who places him among those authors of later times who neglected the graces of style, and who paid for their neglect by leaving behind them works "which no one was patient enough to read through to the end" (*περὶ συνθέσεως, ἀνομιάνων, 4*).

It is to the value and variety of his matter, to his critical insight, breadth of view, and wide research, and not least to the surpassing importance and interest of the period with which he deals, that Polybius owes his place among the writers of history. What is known as to the fortunes of his histories, and the reputation they enjoyed, fully bears out this conclusion. The silence respecting him maintained by Quintilian and by Lucian may reasonably be taken to imply their agreement with Dionysius as to his merits as a master of style. On the other hand, Cicero (*De Off.*, iii. 32) describes him as "bonus auctor in primis"; in the *De Republica* (ii. 14) he praises highly his accuracy in matters of chronology, "nemo in exquirendis temporibus diligentior"; and Cicero's younger contemporary, Marcus Brutus, was a devoted student of Polybius, and was engaged on the eve of the battle of Pharsalia in compiling an epitome of his histories (Suidas, s.v.; Plutarch, *Brut.*, 4). Livy, however, notwithstanding the extent to which he used his writings (see Livy), speaks of him in such qualified terms as to suggest the idea that his strong artistic sensibilities had been wounded by Polybius's literary defects. He has nothing better to say of him than that he is "by no means contemptible" (xxx. 45), and "not an untrustworthy author" (xxxiii. 10). Posidonius and Strabo, both of them Stoics like Polybius himself, are said to have written continuations of his history (Suidas, s.v.; Strabo, p. 515). Arrian in the early part of the 2d and Elian in the 3d century both speak of him with respect, though with reference mainly to his excellence as an authority on the art of war. In addition to his *Histories* Polybius was the author of the following smaller works:—a life of Philopomen (Polyb., x. 24), a history of the Numantine War (Cic., *Ad Fam.*, v. 12), a treatise on tactics (Polyb., ix. 20; Arrian, *Tactica*; Elian, *Tact.*, i.). The geographical treatise, referred to by Geminus, is possibly identical with the thirty-fourth book of the *Histories* (Schweigh., *Præf.*, p. 184).

The complete books (i.-v.) of the *Histories* were first printed in a Latin translation by Nicholas Perotti in 1473. The date of the first Greek edition, that by Obsequius, is 1530. For a full account of these and of later editions, as well as of the extant MSS., see Schweighäuser's Preface to his edition of Polybius. Our knowledge of the contents of the fragmentary books is derived partly from quotations in ancient writers, but mainly from two collections of excerpts; one, probably the work of a late Byzantine compiler, was first printed at Basel in 1549 and contains extracts from books vi.-xviii. (*περὶ ἀπορρήτων, περὶ ἀπορρήτων καὶ ἀπορρήτων*); the other consists of two fragments from the "select passages" from Greek historians compiled by the directions of Constantine Porphyrogenitus in the 10th century. To these must be added the Vatican excerpts edited by Cardinal Mai in the present century.

The following are the more important modern editions of Polybius:—Ernesti (3 vols., 1763-64); Schweighäuser (6 vols., 1793, and Oxford, 1823); Bekker (2 vols., 1843); L. Dindorf (4 vols., 1866-68, 2d ed., Teubner, 1882); Hultsch (4 vols., 1867-71). For the literature of the subject, see Engelmann, *Biblioth. Script. Class. Script. Græci* (pp. 646-650, 8th ed., Leipzig, 1880).

(H. F. P.)

**POLYCARP.** The importance of Polycarp, bishop of Smyrna, for the earliest period of church history arises from his historical position. He was on the one hand a disciple of John and other apostles and disciples of Jesus; on the other hand he was the teacher of Irenæus, the first of the catholic fathers.<sup>1</sup> In his letter to Florinus, Irenæus (ap. Euseb., *H.E.*, v. 20) says:—

"I saw you when I was yet, as a boy, in Lower Asia with Polycarp. . . . I could even now point out the place where the blessed Polycarp sat and spoke, and describe his going out and coming in, his manner of life, his personal appearance, the addresses he delivered to the multitude, how he spoke of his intercourse with John and with the others who had seen the Lord, and how he recalled their words. And everything that he had heard from them about the Lord, about His miracles and His teaching, Polycarp told us, as one who had received it from those who had seen the Word of Life with their own eyes, and all this in complete harmony with the Scriptures. To this I then listened, through the mercy of God vouchsafed to me, with all eagerness, and wrote it not on paper but in my heart, and still by the grace of God I ever bring it into fresh remembrance."

These are priceless words, for they establish a chain of tradition (Jesus, John, Polycarp, Irenæus) which is without a parallel in history. It is all the more to be regretted that

<sup>1</sup> Iren., iii. 3, 4.

Irenæus in his great work<sup>2</sup> has said so little of Polycarp, and that neither Polycrates of Ephesus<sup>3</sup> nor Tertullian<sup>4</sup> mentions anything of importance.

The sources for the life and activity of Polycarp are as follows:—(1) a few notices of Irenæus; (2) the epistle of Polycarp to the church at Philippi; (3) the epistle of Ignatius to Polycarp; (4) the epistle of the church at Smyrna to the church at Philomelium, giving an account of the martyrdom of Polycarp. Since these authorities have all been called in question, and some of them entirely rejected, by recent criticism, it is necessary to say a few words about each of them.

1. Of the statements of Irenæus, those contained in the letter to Victor and in the large work have passed unchallenged. The letter to Florinus, however, which places Polycarp in unequivocal connexion with the apostle John, has been discredited, because, it is alleged, John never was in Asia Minor. But this denial of John's residence in Asia Minor is itself a piece of critical arbitrariness, and to assert that the epistle to Florinus is spurious is a desperate resource. The only argument which can be adduced against it with any sort of plausibility is the fact that in his great work Irenæus does not satisfy the expectations which the letter to Florinus is apt to raise in a modern reader. It is certainly the case that he tells us very little about Polycarp and still less about John. But statements from the mouth of Polycarp of the very kind which the letter to Florinus would lead us to expect are not altogether wanting in the great work of Irenæus (see iii. 3, 4; ii. 22, 5; v. 30, 1)<sup>5</sup>; and that they are so few is accounted for by the plan and object of the treatise. The facts mentioned by Irenæus, therefore, cannot be set aside, although the assertion that Polycarp was appointed bishop of the church at Smyrna by the apostles (iii. 3, 4) is probably a deduction from the Catholic theory of the origin of the episcopate. If it was once understood that Polycarp had seen apostles, the necessary inference for the time of Irenæus was that he had received his office from the hands of the apostles.

2. Under the name of Polycarp we possess, in a Latin translation, a complete letter to the church at Philippi, which was first published by Faber Stapulensis in 1498. Of the Greek original, which was first edited by Halloix in 1633, unfortunately only three-fourths has been preserved.<sup>6</sup> Since Irenæus (iii. 3, 4) expressly mentions and commends a letter of Polycarp to the church of Philippi, since Eusebius (*H. E.*, iii. 36) was acquainted with the epistle as we have it and makes extracts from it, and since Jerome (*De Vir. Ill.*, xvii.) testifies that in his time it was publicly read in the Asiatic churches, the external evidence in its favour is as strong as could be desired. But the internal evidence is also very strong. The occasion of the letter was a case of embezzlement, the guilty individual being a presbyter at Philippi. It shows a fine combination of mildness with severity; the language is simple but powerful; and, while there is undoubtedly a lack of original ideas, the author shows remarkable skill in weaving together pregnant sentences and impressive warnings selected from the apostolic epistles and the first epistle of Clement. There is no trace of any tendency beyond the immediate purpose of maintaining the true Christian life in the church, and warning it against covetousness and against an unbrotherly spirit. In these circumstances it would certainly never have occurred to any one to doubt the genuineness of the epistle, or to suppose that it had been interpolated, but for the fact that in several passages reference is made to Ignatius and his epistles. In point of fact the historical situation which is presupposed by the epistle is this, that Ignatius, on his last journey to Rome, has just passed through Philippi, and that his letters are circulating in the churches. Hence all those scholars who hold the seven Ignatian epistles to be spurious are compelled to regard the epistle of Polycarp as also a forgery,<sup>7</sup> or at least as having been largely interpolated.<sup>8</sup> The interpolation hypothesis, however, breaks down in view of the fact that the first epistle of Clement is quoted even in those passages which are alleged to be interpolated; and besides it is inconsistent with the very obvious arrangement and unity of the composition. On the other hand the

<sup>2</sup> The lost writings of Irenæus may have contained fuller information; see the close of the *Martyrium Polycarpi* in the Cod. Mosq., and the letter of Irenæus to Victor in Eusebius (*H. E.*, v. 24).

<sup>3</sup> Euseb., *H. E.*, v. 24, 4. <sup>4</sup> *De Præscr. Hær.*, 32.

<sup>5</sup> Cf. "Presbyterorum reliquiæ ab Irenæo servatæ," in the *Patr. App. Opp.*, ed. Gebhardt, Harnack, Zahn, vol. i. 2, p. 105 sq.

<sup>6</sup> All the Greek MSS. are derived from a single archetype, in which the epistle of Barnabas followed that of Polycarp, but a sheet of four leaves had been torn out, so that the end of Polycarp's epistle and the beginning of that of Barnabas are missing.

<sup>7</sup> So, for example, Lipsius, Hilgenfeld, and others.

<sup>8</sup> So Dallmann, first of all, then Bunsen and Ritschl (*Entstehung der altkathol. Kirche*, 2d ed., p. 584 sq.).

assumption that the whole work is a forgery is untenable—(1) because in that case we should expect that its tone and language and tendency would be in keeping with the Ignatian epistles, which is very far from being the fact, and (2) because we must assume that Irenæus himself had been deceived by a forged epistle of Polycarp, or else that he had read the genuine epistle, but in the course of the 3d century it had been supplanted by a spurious substitute. Either of these suppositions is extremely improbable, and, since internal marks of forgery are altogether absent, we must rather reverse the argument and say that the epistle of Polycarp is a very important piece of evidence for the historical existence of a bishop of Antioch named Ignatius, for his journey to martyrdom at Rome, and for the fact that on this journey he wrote several letters. In these circumstances it is very desirable that we should be able to fix the exact date of Polycarp's epistle. This unfortunately is impossible, owing to the colourless character of the writing. Still it is noteworthy that there is not a single trace of the time of Trajan, that on the contrary an expression in the seventh chapter seems to presuppose the activity of Marcion.<sup>1</sup> In that case the letter cannot have been written before 140 A.D. The Ignatian epistles and the history of Ignatius furnish no argument to the contrary, for the idea that Ignatius was martyred under Trajan cannot be traced higher than the 3d century,<sup>2</sup> while the chronological indications in the Ignatian epistles themselves point to a later period. The epistle of Polycarp is of more importance for the Ignatian problem than for Polycarp himself. It conveys no distinct impression of his individuality, beyond the fact that the writer of this letter lived wholly in the ideas of the older generation and of the apostles, and would admit no addition to their teaching. That, however, is a feature which harmonizes admirably so far as it goes with the description which Irenæus gives of Polycarp in the letter to Florinus. On account of its dependence on older epistles, the epistle of Polycarp is of great value for the history of the canon. For the constitutional history of the church also it contains valuable materials; but for the history of dogma it is of little use.

3. The epistle of Ignatius to Polycarp is an important document, whether it is genuine or not. It belongs at any rate to the 2d century, so that even if it were spurious it would at least show what conception of the bishop's character was then prevalent. Polycarp appears in the letter as a man of a passive disposition, with too little energy and decision for the vehement Ignatius. The admonitions which Ignatius thinks fit to bestow on Polycarp (c. 1-6) are surprising, when we remember that they are addressed to an old and venerable man. But Ignatius was writing under the consciousness of impending martyrdom, and evidently felt, with all his affected modesty, that this gave him a right to censure the churches and bishops of Asia. To pronounce the epistle spurious on account of its tone is hazardous, because it is difficult to imagine how it could have entered the head of a forger to subject the honoured Polycarp to such treatment at the hands of Ignatius.

4. The most valuable source for the history of Polycarp is the letter of the church in Smyrna about his martyrdom. Eusebius has preserved the greater part of this epistle in his *Church History* (iv. 15); but we possess it entire with various concluding observations in several Greek manuscripts, and also in a Latin translation.<sup>3</sup> The epistle gives a minute description of the persecution in Smyrna, of the last days of Polycarp, and of his trial and martyrdom; and, as it contains many instructive details, and professes to have been written not long after the events to which it refers, it has always been regarded as one of the most precious remains of the 2d century. Certain recent critics, however, have questioned the authenticity of the narrative. Lipsius<sup>4</sup> brings the date of the epistle down to about 260, although he admits many of its statements as trustworthy. Keim<sup>5</sup> endeavours to show in a long dissertation that it could not possibly have been written shortly after the death of Polycarp, but that, although based on good information, it was not composed till the middle of the 3d century. But Keim's own investigation is sufficient to convince every unprejudiced mind that the genuineness of the epistle will bear the closest scrutiny, for the arguments he advances are of no value.<sup>6</sup> The only positions which Keim (following in the wake of others<sup>7</sup>) makes good are that a few slight interpolations<sup>8</sup> have been

inserted in the epistle, and that it was written, not a few days, but perhaps a year or two after the death of Polycarp. The statement in the epistle that Polycarp suffered martyrdom under the proconsulate of Quadratus has quite recently given rise to a voluminous literature. Eusebius in his *Chronicle* gives 166 A.D. as the year of Polycarp's death, and until the year 1867 this statement was never questioned. In that year appeared Waddington's "*Mémoire sur la chronologie de la vie du rhéteur Élius Aristide*" (*Mém. de l'Institut. imp. de France*, 1867, xxvi.), in which it was shown from a most acute combination of circumstances that Quadratus was proconsul of Asia in 155-6, and that consequently Polycarp was martyred on the 23d of February 155.<sup>9</sup> Since the date of Polycarp's death is of great importance for the chronology of many other events, and since it is an unusual thing in the history of criticism for the date of any occurrence to be thus put eleven years farther back, Waddington's arguments have been examined by a great number of critics. Renan,<sup>10</sup> Anbe,<sup>11</sup> Hilgenfeld,<sup>12</sup> Gebhardt,<sup>13</sup> Lipsius,<sup>14</sup> Harnack,<sup>15</sup> Zahn,<sup>16</sup> Egli,<sup>17</sup> and others have declared themselves satisfied, although some scholars regarded 156 as also a possible date. On the other hand Keim,<sup>18</sup> Wieseler,<sup>19</sup> and Uhlhorn,<sup>20</sup> join issue with Waddington and adhere to the date of Eusebius. The arguments on which they rely do not appear to the present writer to be convincing, and it may be asserted with great probability that the martyrdom of Polycarp took place on the 23d of February 155.<sup>21</sup> Besides these we have no other sources for the life of Polycarp. The *Vita S. Polycarpi auctore Pionio* (published by Duchesne, Paris, 1881, and Funk, *Apost. Patr. Opp.*, vol. ii. p. 315 sq.) is worthless.<sup>22</sup>

The chief facts to be gathered about the life of Polycarp from the above sources are these. He must have been born before the year 69, for on the day of his death he declared that he had served the Lord for eighty-six years (*Martyrium*, ix.). He became a Christian in his earliest youth, and was an associate of the apostle John and other disciples of Jesus who had come from Palestine to Asia Minor. What he heard from them he kept in life-long remembrance, and in his manhood and old age he used to gather the young people round him, and repeat to them what he had learned from those who had seen Christ in the flesh. Amongst these youthful hearers was Irenæus, who has recorded much of what he thus learned (for example, an encounter between John and Cerinthus in the bath, a statement about the age of Jesus, &c.). Especially when heresy began to raise its head, the aged Polycarp never ceased to appeal to the pure doctrine of the apostles. He lived to see the rise of the Marcionite and Valentinian sects, and vigorously opposed them. Irenæus tells us that on one occasion Marcion "endeavoured to establish relations with him" (Iren., iii. 3, 4), and accosted him with the words ἐπιγνώσκεις ἡμᾶς; there is no doubt that Marcion wished to be on friendly terms with so influential a man; but Polycarp displayed the same uncompromising attitude which his master John had shown to Cerinthus, and answered ἐπιγνώσκω σε τὸν πρωτότοκον τοῦ Σατανᾶ. These stern words are again applied to Marcion in the epistle to the Philippians; for it is undoubtedly Marcion who is referred to in the following passage (c. vii.):—"He who falsifies the sayings of the Lord after his own pleasure, and affirms that there is no resurrection [of the flesh] and no judgment, is the first-born of Satan." The

<sup>9</sup> He died on a "great Sabbath"—another expression which has given rise to much discussion—by which is meant the Sabbath after Easter. In 155 this fell on the 23d February, and this agrees with what the church of Smyrna says about the day of its bishop's death: ἀπὸ ἐπὶ τὰ καλεσθῶν Μαρτίων.

<sup>8</sup> Amongst these we ought probably to include the expression, ἡ καθολικὴ ἐκκλησία (Inscr., c. xvi. 19), καθολικός being here used in the sense of "orthodox."

steady progress of the heretical movement, in spite of all opposition, was a cause of deep sorrow to Polycarp, so that in the last years of his life (Iren. ap. Euseb., v. 20) the words were constantly on his lips, "Oh good God, to what times hast thou spared me, that I must suffer such things." He never allowed himself to engage in discussion with heretics, but as far as possible avoided their presence. Even in early life he had become the head of the church of Smyrna, where he was held in the highest respect. The congregation looked up to him as an apostolic and prophetic teacher (*Mart.*, xvi.), and consequently as combining in himself all the spiritual gifts which God had conferred on Christendom. In his old age the members of the congregation vied with each other in providing for his support (*ibid.*, xiii.). How great his reputation was is best shown by the fury of the heathen and the Jews in his martyrdom. He was arrested amidst shouts of "This is the teacher of Asia; this is the father of the Christians; this is the destroyer of our gods; this is the man who has taught so many no longer to sacrifice and no longer to pray to the gods" (*ibid.*, xii.). When sentence was pronounced against him, every creature of the Jewish and heathen rabble hastened to add something to the pile of wood on which he was to be burned (*ibid.*, xiii.). They refused to deliver up his bones to the Christians for burial, for, said the Jews to the mob, "The Christians will now forsake the Crucified, and worship Polycarp" (*ibid.*, xvii.). The sacrifice of Polycarp immediately quenched the fury of the multitude, and the persecution ceased. All these facts prove the great influence which the bishop had in the city. But his reputation extended far beyond the limits of his own diocese. His letter to the church at Philippi shows us how fully his apostolic spirit, his wisdom and justice, must have been recognized even in Macedonia; otherwise he could not have ventured to interfere in the purely internal affairs of the Philippian church. Ignatius, the bishop of Antioch, begins his letter to him with the words (c. 1)—*Ἀποδεχόμενός σου τὴν ἐν θεῷ γνώμην, ἡδρασμένην ὡς ἐπὶ πέτραν ἀκίνητον, ὑπερδοξάζω, καταξιώθεϊς τοῦ προσώπου σου τοῦ ἀμώμου, οὗ ὀναίμην ἐν θεῷ*, and, in spite of his patronizing tone, evidently writes with deep respect. But even the church at Rome were to have an opportunity of making the acquaintance of the venerable bishop. It is one of the most interesting and important incidents in the church history of the 2d century that Polycarp, in the year before his death (when he was above ninety years of age) undertook the journey to Rome in order to visit the bishop Anicetus.<sup>1</sup> Irenæus, to whom we are indebted for this information (*Hæc.* iii. 3, 4; *Ep. ad Victorem*, in Eusebius, *H.E.*, v. 24, 16–17), gives as the reason for the journey that differences existed between Asia and Rome, or between Polycarp and Anicetus, "with regard to certain things," and especially about the time of the Easter festival, which it was desirable to remove. He might easily have told us what these "certain things" were, and given us fuller details of the negotiations between the two great bishops; for in all probability he was himself in Rome at the time (*Mart.*, Epilog. Mosq.). But unfortunately all he says is that, with regard to the "certain things," the two bishops speedily came to an understanding, while, as to the time of Easter, each adhered to his

<sup>1</sup> Anicetus was bishop from 154 (156) to 166 (167) (see Lipsius, *Chron. d. Röm. Bischöfe*, § 263.) Those critics who reject Waddington's view as to the date of Polycarp's death use this as their principal argument, that according to it there is no room for Polycarp's journey to Rome. It is certainly remarkable that the journey can just be brought under Waddington's calculations and no more; but, since after all it can be brought under them, no conclusive argument can be drawn from this circumstance. A voyage to Rome at a favourable season of the year was not a very formidable affair, and that Polycarp was still comparatively vigorous is shown by his conduct during the persecution (*Mart.*, v. 29.).

own custom without breaking off communication with the other. We learn further that Anicetus, as a mark of special honour, allowed Polycarp to celebrate the Eucharist in the church (the Eucharist must therefore have still been celebrated at Rome in the Greek tongue), that many Marcionites and Valentinians were converted by Polycarp in Rome (so that his visit must have lasted for a considerable time), and that Polycarp took leave of Anicetus in peace. On his return to Smyrna he enjoyed only about six months of uninterrupted activity. Then, on the occasion of the festive games, there arose, as in so many other instances, an outburst of popular feeling against the Christians, in which Polycarp was to die a martyr's death. From the letter of the church of Smyrna we see with what magnanimity and manliness and true Christian spirit the grey-haired bishop conducted himself. It leaves the most vivid impression of a man of dignity and noble demeanour, and at the same time of humble disposition and compassionate love. Every action he does, every word he speaks, in the prosecution and during the trial is noble and great; even that quiet irony which we detect in his answer to Marcion does not forsake him (*Mart.*, ix. 2). The proconsul was anxious to save him, and tried to induce him to recant, but he remained steadfast. He was delivered up to the populace, and his body was burned. The Christians present believed that they saw a dove soaring aloft from the burning pile, and it was reported that an odour issued from it like that of costly incense (*ibid.*, xvi. 15). Such legends do not require years for their formation, but only a few hours. By his death Polycarp shielded his congregation from further persecution. (A. HA.)

**POLYCLETUS.** Two Greek sculptors bore this name. For an account of the works of the elder, a native of Sicily, see vol. ii. p. 357, and figs. 6, 7. With him is sometimes confounded his younger kinsman and namesake, properly known as Polycleus the Argive. For the most part this younger Polycleus confined himself to statues of athletes who had won prizes at Olympia. In recent excavations there two bases of statues by him have been found, but no remains of his work. From the fact of his having executed a statue of Zeus Philios, i.e., a combination of Zeus and Dionysus, for the town of Megalopolis, which was founded in 371 B.C., we may assign him to about that date.

**POLYCRATES,** a celebrated Greek tyrant of Samos, was the son of *Æaces*. After distinguishing himself by his liberality towards his poorer fellow-citizens he took advantage of a festival to Hera in order to make himself master of Samos (537 or 536 B.C.).<sup>2</sup> Allied with Amasis, king of Egypt, he prospered greatly, so that his fame went forth through all Greece and Ionia. He had 100 ships and 1000 bowmen. He made war indiscriminately on friend and foe, declaring with grim humour that he gratified his friends more by returning to them their own than by not taking it at all. Many islands fell before him and many cities on the mainland. Amongst the former was Rhenea, which he attached by a chain to the neighbouring island of Delos, and dedicated to the Delian Apollo. When the Lesbians would have succoured Miletus, he conquered and captured them in a sea-fight and employed them to dig a moat round the walls of his fortress. According to Herodotus, he was the first within historical times who aimed at the sovereignty of the seas, and his ambitious schemes embraced not only the Greek islands but also Ionia. In magnificence none of the Greek tyrants save those of Syracuse could compare with him.

<sup>2</sup> Eusebius gives the date as 1484 (year of Abraham) = Olymp. 61, 4 = October 533 to October 532. But codex N of the Armenian version of Eusebius has Abrah. 1480 = Olymp. 60, 4 = Oct. 537 to Oct. 536. The former date, accepted by Clinton, would leave only ten years for the tyranny of Polycrates, which seems too little.

His great public works were executed, according to Aristotle, for the purpose of employing his subjects and diverting their thoughts from the recovery of their freedom.<sup>1</sup> He imported Spartan and Molossian hounds, goats from Naxos and Scyros, sheep from Attica and Miletus. The splendour of his palace is attested by the design which many centuries later the emperor Caligula formed of rebuilding it. Foreign artists worked for him at high wages: from Athens he brought Democedes, the greatest physician of the age, at a salary of two talents. Polycrates was also a patron of letters: he collected a library and lived on terms of intimate friendship with the poet Anacreon, whose verses were full of references to his patron. The philosopher Pythagoras, however, quitted Samos in order to escape his tyranny. The good fortune of Polycrates is the subject of a famous story. Amasis, moved with fear at the exceeding great prosperity of his friend, reminded him that God is jealous, and that the man who is uplifted very high must needs fall very low. Therefore he besought him, if he would avert the jealous wrath of heaven, to cast from him that which he valued most. Polycrates hearkened to him and flung into the sea an emerald signet set in gold, the work of the Samian artist Theodorus. But a few days after the signet was found in the belly of a large fish which a fisherman had presented to the king. When Amasis heard of this he knew that Polycrates was doomed, and renounced his alliance. Amasis died before his forebodings were fulfilled. When the Persians under King Cambyses were preparing to invade Egypt, Polycrates, anxious to conciliate the growing power of Persia, sent forty ships to their help (525 B.C.). But the squadron was largely manned by malcontents whom Polycrates had hoped thus to get rid of; hardly had it reached the island of Carpathus when the crews mutinied and turned the ships' heads back to Samos. They defeated the tyrant in an action at sea, but were themselves overthrown in a land battle and compelled to flee the island. Having taken refuge in Sparta, they prevailed on the Spartans to make war on Polycrates. A powerful Spartan armament laid siege to Samos, but was fain to retire after forty days without effecting its object. Not very long afterwards Oroetes, the Persian satrap of Sardes, by working on the avarice and ambition of Polycrates, lured him to Magnesia and put him to a shameful death (522 B.C.).

The name of Polycrates was also borne by an Athenian rhetorician of some repute, who flourished early in the 4th century B.C. He taught at Athens, and afterwards in Cyprus. He composed declamations on paradoxical themes—an *Encomium on Clytemnestra*, an *Accusation of Socrates*, an *Encomium on Busiris* (a mythical king of Egypt, notorious for his inhumanity); also declamations on mice, pots, and counters. His *Encomium on Busiris* was sharply criticized by his younger contemporary Isocrates, in a work still extant, and Dionysius of Halicarnassus characterises his style as frigid, vulgar, and inelegant. Nevertheless his works are said to have been studied by Demosthenes. See Jebb's *Attic Orators*, ii. p. 94; Cope upon Aristotle's *Rhetoric*, ii. c. 24.

**POLYGLOTT.** A polyglott is a book which contains side by side versions of the same text in several different languages; and the most important polyglotts are editions of the Bible, or its parts, in which the Hebrew and Greek originals are exhibited along with the great historical versions, which are of value for the history of the text and its interpretation. The first enterprise of this kind is the famous *Hexapla* of Origen; but here only Hebrew and

Greek were employed (though the versions of Aquila, Symmachus, and Theodotion were shown as well as the Septuagint), so that the work was rather diglott than polyglott in the usual sense. After the invention of printing and the revival of philological studies, polyglotts became a favourite means of advancing the knowledge of Eastern languages (for which no good helps were available) as well as the study of Scripture. The series began with the *Complutensian* (Alcala, 1514–17), already spoken of in the article on its promoter Cardinal JIMENES or Ximenes; next came the *Antwerp Polyglott* (1569–72, in 8 vols. folio) of which the principal editor was Arias Montanus aided by Guido Fabricius Boderianus, Raphelengius, Masius, Lucas of Bruges, and others. This work was under the patronage of Philip II. of Spain; it added a new language to those of the *Complutensian* by including the Syriac New Testament; and, while the earlier polyglott had only the Targum of Onkelos on the Pentateuch, the Antwerp Bible had also the Targum on the Prophets, and on Esther, Job, Psalms, and the Salomonic writings. Next came Le Jay's *Paris Polyglott* (1645), which embraces the first prints of the Syriac Old Testament (edited by Gabriel Sionita, a Maronite, but the book of Ruth by Abraham Ecchelenensis, also a Maronite) and of the Samaritan Pentateuch and version (by MORINUS, *q.v.*). It has also an Arabic version, or rather a series of various Arabic versions. Le Jay's work is a splendid piece of typography, but its success was marred by the appearance of the cheaper and more comprehensive *London Polyglott*. Le Jay was ruined, and a great part of the impression went to the trunkmakers. The last great polyglott is Walton's (*London*, 1657), which is much less beautiful than Le Jay's, but more complete in various ways, including among other things the Syriac of Esther and several apocryphal books for which it is wanting in the Paris Bible, Persian versions of the Pentateuch and Gospels, the Psalms and New Testament in Ethiopic. Walton was aided by able scholars, and used much new manuscript material. His prolegomena, too, and collections of various readings mark an important advance in Biblical criticism. It was in connexion with this polyglott that E. Castle produced his famous *Heptaglott Lexicon* (*London*, 2 vols. folio, 1669), an astounding monument of industry and erudition even when allowance is made for the fact that for the Arabic he had the great MS. lexicon compiled and left to the university of Cambridge by the almost forgotten W. Bedwell. The later polyglotts are of little scientific importance, the best recent texts having been confined to a single language; but every Biblical student still uses Walton and, if he can get it, Le Jay. Of the numerous polyglotts on parts of the Bible it may suffice to mention the Genoa psalter of 1516, edited by Giustiniani, bishop of Nebbio. It is in Hebrew, Latin, Greek, Chaldee, and Arabic, and is interesting from the character of the Chaldee text, from being the first specimen of Western printing in the Arabic character, and from a curious note on Columbus and the discovery of America on the margin of Psalm xix.

**POLYGNOTUS**, a Greek painter. For a description of his work see vol. ii. p. 358. It may here be added that an approximate date for his paintings at Delphi is obtained from the fact that one of them was inscribed with an epigram written by the poet Simonides, who died 467 B.C. As Simonides appears to have resided in Sicily during the last ten years of his life, the epigram was probably composed previous to 477 B.C. This series of mural paintings at Delphi, embracing about one hundred and forty-six figures, seems to have occupied two opposite walls of an oblong building known as the Lesche. The figures, hardly under life size, were disposed in two or sometimes

<sup>1</sup> Herodotus, our chief authority for the life of Polycrates, mentions three great engineering and architectural works for which Samos was remarkable:—(1) a tunnel, about 1400 yards long, dug through a mountain, and serving to bring water to the capital; (2) a great mole or breakwater round the harbour; (3) a great temple (the temple of Hera, patron goddess of Samos), said by Herodotus to be the largest he had ever seen. But we cannot say what share Polycrates had in these works; certainly the temple of Hera seems to have been begun before his time.

three rows, the one higher up than the other, with apparently but very slight indications of the fact that the figures of the upper rows were to be understood as standing at a more remote distance. The several rows would run continuously like sculptured friezes, and indeed this manner of composition is best illustrated by the friezes at Vienna recently found at Gjölbaxhi in Lycia, some of which present subjects and motives identical with those treated by Polygnotus.

POLYHISTOR, CORNELIUS ALEXANDER, a Milesian and disciple of Crates,<sup>1</sup> who through the fortune of war became the slave and afterwards the freedman of Cornelius Lentulus (Suidas). He received the Roman citizenship from Sulla (Servius on *Æn.* x. 388), and wrote an enormous number of books on historical and geographical subjects, of which more than a hundred and fifty fragments have been collected (Müller, *Fr. Hist. Gr.*, iii. 206 sq.). His account of the doctrines of Pythagoras has been largely drawn from by Diogenes Laërtius, but the most interesting of the fragments refer to the history of the Jews, for which Alexander drew on historical and poetical works of Jewish and Samaritan Hellenists. What has been preserved on this subject, mainly by Eusebius in the *Præparatio Evangelica*, is sufficient to throw a good deal of light, not particularly favourable, on the intellectual activity of the Hellenists of the 2d century B.C.

See J. Freudenthal, *Hellenistische Studien*, i. ii. (Breslau, 1875), in which the subject of the sources of Polyhistor is fully discussed.

Plate III.

**POLYNESIA.** In the last edition of the *Encyclopædia Britannica* Polynesia was used to denote all the intertropical islands of the Pacific Ocean eastward of the Philippine Islands to the north and the New Hebrides to the south of the equator. The New Hebrides and other islands west of that group were included under the term Australasia. Of late years these islands (sometimes also including Fiji) have been known as Melanesia, while the western islands of the North Pacific have been known as Micronesia. Thus Polynesia has been restricted to the central and eastern islands inhabited by the brown or Sawaiori race, becoming an ethnographic rather than a geographical term. Articles dealing with the western islands north and south of the equator will be found under MICRONESIA and MELANESIA. The present article is intended to give a comprehensive view of all the islands of the Pacific, their physical characteristics, natural productions, and the races of men found upon them. The name Polynesia is therefore here employed in a wide signification and solely as a geographical term. The western boundary of this region runs from the great barrier reef of Australia eastward of New Guinea and the Philippine Islands. All the intertropical islands of the Pacific eastward of this imaginary line are included, and also a few others which extend outside the tropic of Capricorn to nearly 30° S. lat. Any other divisions for geographical purposes, except those of groups of islands, appear to be unnatural and uncalled for. For ethnographical purposes special terms are used for the three different classes of people found in this wide area.

If we exclude NEW CALEDONIA (*q.v.*), which is of older formation than the rest, all the islands of Polynesia are either of volcanic or of coral formation. Some are purely coral, either in the shape of low atolls or of elevated plateaus. In a few atolls there are remnants of earlier volcanic rocks; and most of the volcanic islands are more or less fringed with coral reefs. But, notwithstanding

this mixture, the islands must be divided broadly into those which are volcanic and those which are of coral formation. The coral islands must again be subdivided into (1) atolls, or low islands which usually have a lagoon within them, and (2) elevated table-lands.

The volcanic islands, with the exception of the Hawaiian archipelago, are all south of the equator. In Plate III. the great volcanic ridge is indicated by two lines which, commencing in 150° E., run in a south-easterly direction to about 140° W. long. With the exception of two curves, one in the lower line south of the New Hebrides, and one in the upper line at its eastern extremity, these are parallel, and are 10° apart. Within these two lines lie all the volcanic islands of Polynesia, except two isolated groups, viz., the Marquesas and Hawaiian Islands. On this ridge there are no atolls. The upper boundary line sharply divides the volcanic ridge from the atoll valley. This valley is indicated by a third line running for more than 50° of longitude parallel with the other two, at 20° distance from that bounding the northern extremity of the volcanic ridge. Eastward of 155° W. long. this line bends towards the south to exclude the isolated volcanic centre of the Marquesas Islands; then, curving around the Tuamotu archipelago, it joins the central line. Within the area thus enclosed lie all the atolls or low coral lagoon islands of Polynesia, and there are no volcanic islands within this region except in three or four instances, where are found the remnants of former islands which have sunk, but have not been quite submerged. This is the region of subsidence—stretching across fully 100° of longitude, and covering generally about 20° of latitude.

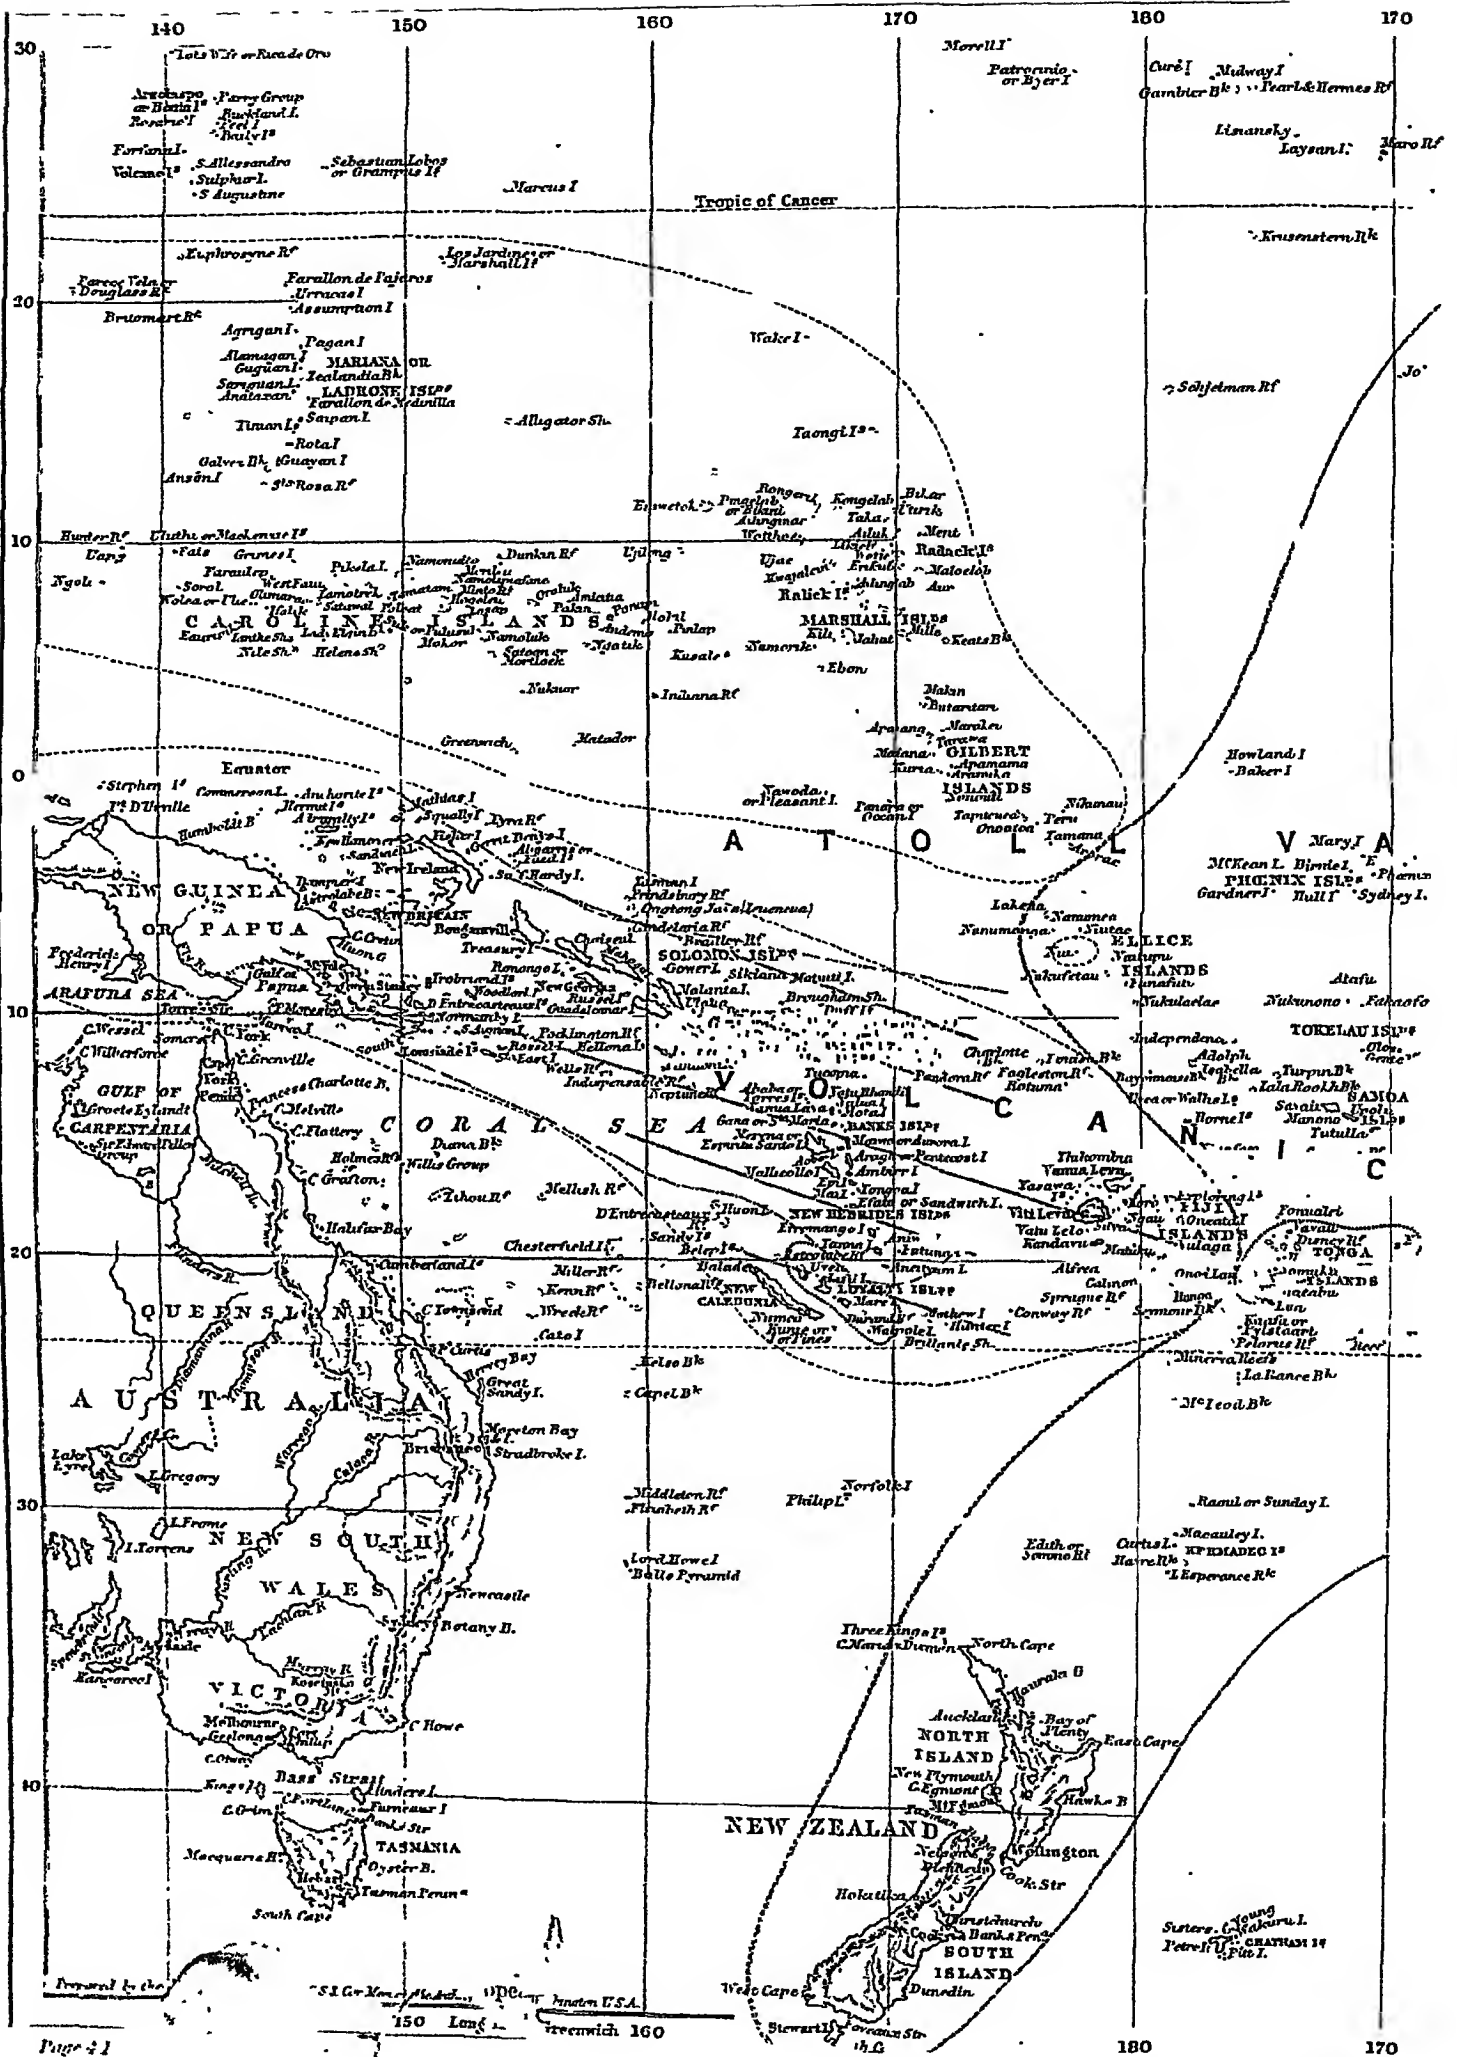

Within the volcanic region there are a few coral islands, but these are all more or less elevated. Since their formation they have participated in the upward movement of the ridge on which they are situated. They are indicated on the map by dotted lines. Two of the groups are within the lines marking the volcanic ridge; and one, the Loyalty group, lies close to the lower line.

*The Volcanic Islands.*—Most of the volcanic islands of Polynesia are high in proportion to their size. The tapering peaks, or truncated cones, which form their backbones present a picturesque appearance to the voyager as he approaches them. In some there are precipitous spurs jutting into the sea, while in others the land slopes gently from the central peak to the shore. Where there are these gentle slopes, and wherever there is any low land near the shore, there also will be found a coral reef fringing the coast at a smaller or greater distance, according to the steepness of the land under the water. Where the trend downwards is very gradual, the edge of the reef will sometimes be one, two, or even three miles to seaward. It has been thought that the absence of extensive reefs in some islands of the New Hebrides is due to "subterranean heat." But the steepness of the slope of the islands under water is doubtless the reason why the reefs are small. As the reef-building coral polypes do not live and work below a certain depth—about 20 fathoms, or 120 feet—we easily see that the distance of the outer edge of the reef must be according to the slope of the island beneath the water. Opposite to the larger valleys, where there is a stream flowing out to sea, there is usually found a break in the reef. This is doubtless caused either by the fresh water, or by the sediment which it contains, injuring the coral polypes and preventing them from effectively carrying on their work in these spots. The conviction of the present writer is that it is the sediment contained in the water—especially during heavy rains and consequent freshets—which prevents the growth of the coral, rather than the mere action of fresh water upon the polypes. Where there are streams of considerable

<sup>1</sup> From the scholiast on Apoll. Rh., l. 925, it would appear that Polyhistor was a Milesian only by education, for here the Carian Chersonese is named as his birthplace. The dates seem to show that he was not a personal disciple of Crates.

size, and especially where they are subject to floods, there are generally wide openings into the reef, and stretches of deep water forming natural harbours sufficient for the accommodation of even large vessels. There are a few land-locked harbours, but most are thus formed by breaks in the reef.

In a few spots active volcanoes are still found. These are in the neighbourhood of New Britain and New Ireland, in the Solomon, New Hebrides, and Tonga archipelagoes. In most of the islands there have been no recent eruptions; but now and again the inhabitants of islands where volcanic action has apparently long ceased have been startled by a new outbreak. Over the whole region earthquakes are of frequent occurrence. Most of the craters in the islands of Samoa have immense trees growing in them, and there is only one crater in the entire group which shows signs of even a comparatively recent eruption, or concerning which there is a tradition among the people of one. Yet in 1867, after an almost continuous succession of earthquakes during a whole night, there was a submarine eruption between two of the islands. This lasted only a few days. A few months afterwards the writer was on board H.M.S. "Falcon" when soundings were taken on the spot. A cone was found the summit of which was 90 fathoms deep, while all around the sea was 120 fathoms deep. Thus the outpourings of this submarine volcano during only a few days raised a mound in the bed of the ocean 180 feet in height.

The soil in the volcanic islands is generally very fertile. The climate is hot and moist in most of them; consequently the vegetation is wonderfully rich. The islands are densely clothed with the most luxuriant verdure from the sea-beach to the summits of the mountains. While in a few islands, especially the comparatively barren ones (barren is only a comparative term as applied to any of the volcanic islands), there is sometimes grand and bold scenery, in most of them the jagged and precipitous rocks are so covered up and rounded off with the rich vegetation that they lose much of their grandeur. The atmosphere is so laden with moisture that ferns, club-mosses, and even small shrubs grow upon the faces of the steepest rocks. Mainly on this account the scenery can rarely be said to be grand; but nearly all these islands are truly beautiful. There is a freshness about the vegetation all the year round which is rarely seen in other portions of the world. The cocoa-nut palm groves, which are usually abundant on the low lands near the sea, always give a charm to the islands as they are approached. In addition to several species of palms, beautiful ferns, dracenas, crotons, and other elegant foliage plants abound. Pines are found on some of the western islands. For flowers none of them will compare with the hedgerows and meadows of England. There are, it is true, many most beautiful and sweet-scented flowers, but they are not usually found in great profusion.

Fruits are abundant. Some of the indigenous kinds are good, and many of the best productions of other tropical countries have been introduced and flourish. Oranges are very plentiful in many islands; also pine-apples, guavas, custard apples, and bananas. The mango has been introduced into some islands, and flourishes well. Most of these fruits have been introduced by missionaries. One of the fruits most abundantly used, both in a ripe state and cooked when unripe as a vegetable, is the Chinese banana, *Musa Cavendishii*. The first plant of this carried to the islands was in a case of plants given by the duke of Devonshire to the missionary John Williams when he returned from England to the Pacific shortly before he was killed on Erromanga. During the long voyage all the plants in the case died except this banana.

When it reached Samoa it was carefully cultivated by one of the missionaries and a stock of it was propagated. From the single plant all the Chinese bananas in Polynesia have sprung, and that particular kind being greatly prized both by natives and foreign settlers, it is now grown largely wherever missionaries or traders have gone, and must produce annually hundreds of tons of nutritious food.

The natives live chiefly upon vegetable food. In most of the volcanic islands the taro (*Colocasia esculenta*) is the most important food-producer. Next to this comes the yam (*Dioscorea sativa*). Probably next in importance to this are the plantains and bananas, then the bread-fruit (*Artocarpus incisa*) and arrowroot (*Tacca pinnatifida*). The bread-fruit is more or less plentiful in most of the volcanic islands, and during one season of the year the natives very largely subsist upon it. It is not, however, by any means so nutritious as the taro or the yam. This vegetable is often spoken of in Britain as if it were a rich fruit, but one would as soon eat a raw potato as a raw bread-fruit. It has been over-estimated by many writers who have visited the Pacific. The present writer has noticed that the Samoans suffered in condition, that sickness among children was very common and the rate of mortality high during the bread-fruit season. Although the raw cocoa-nut is not eaten to any considerable extent by the natives of volcanic islands, this must not be omitted in an enumeration of the principal articles of their food supply, for it enters into the composition of most of their made dishes in the form of expressed juice or oil; the soft half-grown kernel is used as a kind of dessert, and the liquid from it, when the kernel is only half developed, is one of their principal beverages. The *Ava*, or *Kava*, a narcotic drink largely used, is made from the root of a pepper (*Piper methysticum*).

In some islands the cocoa-nut is the chief article of commerce. The fully-grown kernel is cut into slices, dried in the sun, and sold as "cobra," from which much of the palm oil of commerce is expressed. On many islands cotton is largely grown, and on a few, especially in the Hawaiian archipelago, sugar cultivation has made considerable progress. Many other vegetable products might be utilized if there were a demand for them. The candle-nut (*Aleurites triloba*) is abundant everywhere near the coast. Coffee has not been grown to any considerable extent. Wild ginger and wild nutmegs are abundant on some of the islands. In some places indigo has been introduced, and has spread so much as to become a nuisance. All the islands have numerous valuable fibre-producing plants belonging to the *Urticæ* and *Malvaceæ*. But the probability is that, on these hot, moist, and fertile islands, cocoa-nuts, cotton, or sugar will always be the most profitable crops to cultivate for exportation.

The indigenous fauna of Polynesia is poor in mammals but rich in birds. Mammals are represented by rats and bats, the latter including the flying foxes (*Pteropus*). Some say pigs are indigenous, but they were doubtless introduced by early navigators. Horses and cattle have been introduced. They degenerate very rapidly, unless they are continually improved by newly-imported stock. Sheep and goats are introduced into some islands, but sheep do not usually thrive. Dogs are plentiful, being kept by most of the natives, who are naturally fond of domestic animals; but they degenerate greatly. Pigeons and doves, especially the fruit-eating pigeons (*Carpophaga*) and doves of the genus *Ptilinopus*, are abundant. The *Carpophaga* furnish a very important article of food in some of the islands. Some of the species of *Ptilinopus* are exceedingly beautiful. *Megapodes* are found in a few of the western islands; the *Iagu* (*Rhinocetus jubatus*) has

its home on New Caledonia; and in Samoa the *Didunculus strigirostris* has its habitat. This bird is remarkable as being the nearest relative of the extinct dodo. Some time ago it was rarely found, and was becoming extinct. It fed and nested on the ground, and was destroyed by cats and rats after they were introduced. Of late it has changed its habits: it now feeds, nests, and roosts upon trees, and is, in consequence, increasing in numbers. Certain non-venomous snakes are found in many of the islands. Insect life is abundant, and some of the butterflies are very beautiful.

The lagoons formed by the coral reefs around the islands invariably abound in fish, many of them most gorgeous in their colouring,—varying in this respect with the parrots of Australia. Fish form a very important part of the food supply.

One of the most wonderful creatures in the marine fauna of Polynesia is the palolo (*Palola viridis*), an annelid which appears upon the surface of the ocean, near the edge of the coral reef, at certain seasons of the year. The palolo are from 9 to 18 inches long, and about  $\frac{1}{16}$  of an inch thick. They are eaten by the natives, and are esteemed a great delicacy. They live in the interstices of the coral reef, and are confined to a few localities. About 3 o'clock on the morning following the third quartering of the October moon they invariably appear upon the surface of the water; generally they are in such quantities that they may be taken up by the handful. Soon after the sun rises they begin to break, and by 9 o'clock they have broken to pieces and disappeared. The morning following the third quarter of the November moon they again appear in the same manner, but usually in smaller quantities. After that they are not again seen until October of the next year. They appear thus to deposit their ova, which is done by the breaking to pieces of the female worms; the males also break in the same manner, the ova being fertilized while floating in the water. Thus the parents are destroyed in propagating their species. The eggs gradually sink down to the reef where they are hatched. The young palolo then live about the reef until the next year, when they repeat the process. Year by year these creatures appear according to lunar time. Yet, in the long run, they keep solar time. This they do by keeping two cycles, one of three years and one of twenty-nine years. In the short cycle there are two intervals of twelve lunations each, and one of thirteen lunations. These thirty-seven lunations bring lunar time somewhat near to solar time. But in the course of twenty-nine years there will be sufficient difference to require the addition of another lunation: the twenty-ninth year is therefore one of thirteen instead of twelve lunations. In this way they do not change their season during an entire century. So certain has been their appearance that in Samoa they have given their name to the spring season, which is *vae-palolo*, or the time of palolo.<sup>1</sup>

*The Atolls.*—The atolls differ in almost every respect from the islands of volcanic origin. Little that is said of one class would be true of the other. These coral islands are all low, generally not more than 10 or 12 feet above high-water mark. They are simply sandbanks formed by the accumulation of debris washed on to the reefs during strong winds. Hence they are usually in the shape of a narrow band, varying from a few yards to one-third of a mile across, near the outer edge of the reef, with a lagoon in the centre. In some of the smaller atolls the circle of land is almost or entirely complete, but in most of those of larger dimensions there are breaks to leeward, and the sea washes freely over the reef into the lagoon. Where the circle of land is complete the sea-water gains access to the central lagoon through the reef underneath the islands. In some it bubbles up at the rise of the tide in the midst of the lagoons, forming immense natural fountains. This has been observed producing a specially fine effect at Nui in the Ellice group. Some of these atolls are not more than 3 or 4 miles in their greatest length. Others are many miles long. They are not all circular, but are of all conceivable shapes.<sup>2</sup>

Two of the atolls known to the present writer are remarkable. The lagoons in them are of fresh water. One of these is Lakena in the Ellice group, the other Olo-senga, or Quiros Island, in 11° 2' S. lat. and 171° W. long. Both are small circular islands, and in both the lagoon is shut off from the sea. Olo-senga is less than 4 miles in diameter, the lagoon occupying over 3 miles, leaving a ring of land around it less than half a mile across. In some places the lagoon is at least 6 fathoms deep. This bulk of fresh water cannot, therefore, be the result of drainage. There is much to favour the opinion that both this island and Lakena are situated over the craters of former volcanoes, and that there is submarine connexion between them and some of the larger islands situated on the volcanic ridge from which the body of fresh water must come. Olo-senga is about 200 miles distant from Samoa. In that group mountain streams sometimes fall into chasms and totally disappear underground. In this way subterranean lakes may be formed in some of the cavities which we may suppose volcanic eruptions to leave. It is not difficult to suppose that there would be subterranean connexion between these lakes and an isolated crater 200 miles distant. If so, as the crater participated in the subsidence of the region on the edge of which it is situated, the water would rise in it until, if the supply were sufficient, it there found an outlet. This appears to be what occurs at Olo-senga. The lake has never been properly examined and sounded. It is, however, of considerable depth in the centre, where the water is said sometimes to bubble up as if from a great spring, and at low tide it is seen to percolate through the sand on the outer or sea side of the land.

The vegetation of the atolls is extremely poor, not more than about fifty species of plants being found in the Tokelau, Ellice, and Gilbert groups, in all of which groups collections have been made. All the species consist of littoral plants found in the volcanic islands. Most of them have their seeds enveloped in thick husks, which specially fit them for being carried by currents. Doubtless it is in this way that the atolls have received their flora. The cocoa-nut is abundant on most of these islands. This most useful palm will grow on any sandbank in the tropics, and it is benefited by having its roots in soil saturated with sea water. Unlike the natives of volcanic islands, those dwelling on the atolls eat the raw kernel of the nut in large quantities. Indeed that, with fish and the fruit of a screw-pine (*Pandanus*), constitutes the main food supply on some atolls. The people make the pulp of the pandanus into a kind of cake, in appearance much like a quantity of old dates. In some atolls a somewhat elaborate system of cultivation has been adopted, by means of which a coarse kind of taro, banana, the bread-fruit, &c., are grown. These low islands suffer much from drought, and the natural soil is nothing but sand. The people, therefore, form wide trenches by removing the sand until they get within about 2 to 3 feet of the sea-level. Into the trenches they put all the vegetable refuse and manure they can obtain, and, as there is more moisture at this level, these excavated gardens are comparatively fertile. Under the influence of a Christian civilization, which is growing, and by the introduction of new food-producing plants, the condition of the natives is improving; but they still suffer much at times from long-continued seasons of drought.

The fauna of the atolls consists mainly of a few birds, some lizards, and insects. Fish abound about the reefs, and most of the natives are deep-sea fishermen. In the Ellice Islands the people domesticate frigate-birds. Large numbers of these pets may be seen about the villages.

<sup>1</sup> For fuller details, see article by the present writer in *Proc. Zool. Soc. of Lond.*, 1875, p. 425.

<sup>2</sup> On the formation of atolls and of coral reefs generally, see *CORALS*, vol. vi. 277, and *PACIFIC*, vol. xviii. p. 123.

As the birds are accustomed to visit different islands when the wind is favourable, the people send by them small presents (fish-hooks, &c.) to their friends. Christian missionaries also occasionally use them as letter-carriers for communicating with one another.

*Elevated Coral Islands.*—There are comparatively few of the elevated coral islands in Polynesia, but they are so distinct from both the atolls and the volcanic islands that they need a separate description. They all lie within or near the lines marking off the volcanic ridge upon the map. South of the volcanic ridge there are many coral reefs forming shoals. The elevated coral islands doubtless were once such reefs. Lying within the area of volcanic action, they have participated in the upward movement, and have been raised from shoals to become islands. Some have evidently been lifted by successive stages and apparently by sudden movements. This is clearly seen in the Loyalty Islands. On approaching them one sees high coral cliffs, in appearance much like the chalk cliffs of England, except that they are often some distance inland and not close on the shore. The island of Maré may be taken as a good type of the class. Here, between the shore and the coral cliffs, there is a tract of level land varying from a few yards to perhaps one-fourth of a mile or more across. On this level tract the people mainly dwell. At the back of this there rises a perpendicular wall of coral, in some places as much as a hundred feet high. The cliff is water-worn, and has in it large caverns, showing that for a long period it was the coast-line. Still farther inland there are two similar though smaller cliffs, indicating that there were three distinct upheavals. These must have been at very long intervals. At present the island is fringed with a coral reef, and if it were now to be lifted from fifty to one hundred feet the present coast-line would form another cliff, while the present coral reef would form another low plot similar to that upon which the people now dwell.

These islands are old enough to have a considerable depth of vegetable soil upon them. The low land between the coast and the first cliff is well stocked with cocoa-nut and other trees. None of the islands can be compared with the volcanic islands for fertility, all having a less rich soil and being much drier; still they are fairly fertile. They suffer sometimes from drought, but are much less seriously affected in this way than the atolls.

The flora of the elevated coral islands is less rich than that of the volcanic islands, but much richer than that of the atolls. The island of Niue may be taken as a fair specimen of this class. Its flora probably contains between 400 and 500 species, nearly all being such as are found on adjacent volcanic islands. The fauna is also much richer than that of the atolls, but poorer than that of the volcanic islands. Birds are numerous. While most of the species are identical with those found in neighbouring volcanic islands, there are some interesting local variations well illustrating the modifications which take place from isolation under changed surroundings. In some instances the differences are so great that local forms have been classed not only as varieties but as distinct species.

*Climate.*—The climate of the islands varies considerably, as may be naturally expected when the wide area covered is remembered, and the vast difference there is between the islands themselves. Some, especially the elevated coral islands, are very healthy for tropical regions. Speaking generally, the average reading of the thermometer over a large extent of Polynesia is about 80° Fahr. It very seldom sinks lower than 60°, and, owing to the small size of most of the islands, and the prevalence of trade-winds during the greater portion of the year, the heat is always moderated, and rarely becomes intense. Yet, owing to the

constant heat and to the humidity of the atmosphere, the climate in the mountainous islands is trying to the European constitution. But in this respect there is a great difference even between groups which, looked at superficially, appear to be similar, and which lie within almost the same parallels of latitude. All the islands eastward from and including Fiji are much more healthy than are those to the west. In the eastern section fever and ague are of rare occurrence; in the western section European missionaries do not find it expedient to remain for long periods on the islands owing to the weakening effects of frequent attacks of these diseases. The most remarkable thing is that natives of the eastern section suffer even more than Europeans when they go to live in the western islands, the mortality among them being very great. Numerous attempts have been made to evangelize the New Hebrides through the agency of natives of the Samoan, Cook, and Society groups; but, owing to the great mortality among the agents, their efforts have failed. Yet these people have lived there under conditions very similar to those they were accustomed to at home, the heat being about the same, and the food similar, as well as the general mode of life. The causes of the difference are as yet unknown. Possibly the explanation will be found in differences of natural drainage. It has often occurred to the present writer, though only as an unverified theory, that the bases of these western islands are, like that of New Caledonia, of older formation, and that the islands are only superficially volcanic. If so, this may account for their unhealthiness as compared with the purely volcanic islands within the same parallels of latitude. In comparison with most tropical countries there is little dysentery in Polynesia; but this also is more common in the west than in the east.

The elevated coral islands are always much more healthy than are those of volcanic formation in their immediate neighbourhood. They are drier, being always well drained, have much less dense vegetation, and receive the benefit of the trade-winds which blow right across them. They, however, sometimes suffer from drought such as is unknown on the volcanic islands. The atolls may be called—if the term can be applied to tiny islets scattered over the expanse of ocean—the deserts of the Pacific. The soil being almost entirely sand, and the vegetation affording little shade, the heat and glare, especially of those lying close to the equator, are exceedingly trying to European visitors. Being so low—only a few feet above the ocean—there is nothing to attract the clouds, and the rainfall is small. The islands are therefore subject to frequent droughts, which are sometimes of month's duration; and at such times even the fronds of the cocoa-nut palm get a shrivelled appearance, and the trees cease to bear fruit. Sometimes the people suffer greatly during these long-continued droughts, many being starved to death. At best their food supply is confined to cocoa-nuts, pandanus, fruit, and fish, but in times of drought they are forced to chew the roots of shrubs.

*Hurricanes.*—A great portion of southern Polynesia is subject to destructive cyclones. The tract over which they pass may be said to be, generally, that of the volcanic chain indicated by the lines on the map, although the northern edge of this region is not so subject to cyclones as the southern portion. A line drawn parallel to the lines of the map, through the middle of the New Hebrides group, and extending south of Fiji, will well represent the centre of the cyclone tract. The hurricane season is from December to April. Some islands are visited by a more or less destructive cyclone nearly every year; Samoa lies on the upper edge of the tract, and gets one, on an average, about every seven or eight years. Although these cyclones

are not usually so severe as those which visit the seas of eastern Asia, they are often exceedingly destructive, sweeping almost everything down in their course. They last only a few hours. Heavy seas are raised in the line of progress, and vessels are generally exposed to greater danger when lying at anchor at the ports than when in the open sea. The cyclones are always accompanied by considerable electric disturbances, especially when they are passing away.

*Diseases.*—Apart from the fever, ague, and dysentery already alluded to, there is comparatively little disease in any portion of Polynesia. The principal purely native diseases are such as affect the skin. A form of elephantiasis prevails more or less on all the damp mountainous islands. Many Europeans are subject to it, especially those who are much exposed to the sun by day and the dew by night. In some of the atolls where the people have little good vegetable food and eat a great quantity of fish, much of it often in a state unfit for food, skin diseases are even more common than in the mountainous islands. There are reputed cases of leprosy in the Gilbert Islands, and that disease is well known to be one of the scourges of the Hawaiian archipelago. Several European diseases have been introduced into the islands,—those which are epidemic usually, at the first visitation, working great havoc among the natives. Many in Europe and America appear to attribute the great mortality which occurs among native races, when an epidemic is introduced among them, to weakness and want of stamina in their constitution; but a more probable explanation is found in the fact that, on the introduction of measles or smallpox, all the inhabitants of an island are suitable subjects, that the population of entire villages are prostrated at once, that there are no doctors or nurses, none even to feed the sick or to give them drink, and not even the most ordinary care is taken by the sufferers themselves to lessen the danger.<sup>1</sup> In some islands, especially the Hawaiian group, syphilis, first imported by Captain Cook's expedition, has wrought great havoc. It spread very rapidly, because, at that time, there was almost promiscuous intercourse between the sexes; and this has been one of the chief causes of the physical deterioration and of the rapid

they are considerably mixed with the lighter race, and in many places within the region occupied by them are colonies of the light people who keep themselves distinct. For this dark race the name Papuan is here used. They have generally been known of late years as Melanésians, but Papuan is an older name which has always been used for part of the race, and which clearly ought to be extended to the whole. The region which they inhabit is coloured yellow on the map, and the pink bands across it indicate the presence of some of the light race there.

The whole of eastern Polynesia is inhabited by a light brown people to whom the name Sawaióri is here given.<sup>2</sup> They extend out of Polynesia to New Zealand. They have also formed colonies among the Papuans in various places, and in some instances they have become mixed in blood with the blacks among whom they have settled. The pink colour in the map indicates this region.

The third kind of people, here called Tápou, inhabit the northern portion of western Polynesia, the islands generally known as Micronesia (coloured green on the map).

The following table shows the relationship of the Indo-Pacific races (Polynesian names in italics):—

		Races.	Countries where found.
Indo-Pacific Races of Men.	Dark People: Negrito- Polynesians.	Austral.	Australia.
		Negrito.	Andaman Islands. Samang, &c. Aru Islands.
		Papuan.	Western New Guinea. Solomon Islands, &c. New Hebrides, &c. Fiji.
	Brown People: Malayo- Polynesians.	Sawaióri.	Samoa, &c. Hawaii. Cook Islands, &c. Society Islands, &c. New Zealand.
		Malagasy.	Madagascar.
		Formosan.	Formosa.
		Malayan.	Malays of Sumatra, &c. Java, &c.
		Tápou.	Caroline Islands. Marshall Islands. Gilbert Islands.

1. *The Papuans.*—This name is that used by the Malays of the Indian Archipelago for the black, frizzly-haired people found in the Aru Islands and New Guinea. That the inhabitants of the western portion of Polynesia ought to be classed with these Papuans there can be no doubt. The older name is therefore adopted here to include the whole, rather than the newer and less distinctive name Melanesian which has been applied to only a part of the race. A general description of the people is all that can be given here; for further details the reader is referred to the articles MELANÉSIA, NEW GUINEA, &c. In speaking of the affinities of the Papuans with other peoples much caution is required; but there is some reason for thinking they may be remotely classified, together with all the other black people of the southern hemisphere, with the tribes of South Africa.<sup>3</sup> See NEGRO.

The Papuans are mostly black, but are not of a jet black. In some islands they are lighter than in others. It was long popularly supposed that their hair grew in small tufts. This was, however, a mistake which probably arose from the manner in which many of them are accustomed to dress it. On some islands the men collect their hair into small bunches, and carefully bind each bunch round with fine vegetable fibre from the roots up to within about two inches of the ends. Dr Turner<sup>4</sup> gives a good description of this process. He once counted the bunches on a young man's head, and

<sup>2</sup> There has hitherto been no one well understood name used for this people. They are generally called "Polynesians" simply, sometimes "Malayo-Polynesians," and recently the name "Mahori" (a vile corruption of "Maori") has been proposed for them. For evident reasons we need some more distinct name than Polynesian. Malayo-Polynesian cannot be confined to them, but must rather be extended to the whole family of which they are but a branch. *Sawaióri* is a compound from *Sa-moa*, *Ha-wai-i*, and *Ma-ori*, thus derived from the native names of the three principal peoples.

<sup>3</sup> The name "Micronesians" has been generally adopted. Mr Horatio Hale, in his great work on the *Ethnography and Philology of the United States Exploring Expedition*, adopted *Tápou*—the name of one of the Gilbert Islands, there being no native name for the entire group—for the language of that group. The present writer takes part of this name, *Tár-a-wa*, and part of the name of the principal island in the Caroline Islands, viz., *Pou-a-pe*, to form the compound name *Tár-a-pon*.

<sup>4</sup> The Rev. R. H. Codrington believes the Papuan (Melanesian) languages belong to the same stock as the rest of the Polynesian languages. But, as is pointed out by Prof. Keane, he entirely overlooks the physical aspects of the question. See *Journ. Anthropol. Soc. Lond.*, 1884.

<sup>5</sup> *Nineteen Years in Polynesia*, pp. 77, 78; *Summa*, pp. 305-310.

found nearly seven hundred. He calls attention to the resemblance between the head of a Papuan, with his hair thus dressed, and the conventional representation of the hair in Egyptian and Assyrian sculptures, and to what Dr Livingstone says about the Banyai of South Africa, who dress their hair in a similar manner. When allowed to grow naturally, the hair of a Papuan is always frizzly. Some of the people have a considerable beard.

In the features of the Papuans there is considerable difference; but in a typical specimen the lips are thick, the nose is broad, often arched and high, and the jaws project; as a rule, the race is prognathous. They are generally small in stature, but in some islands are large. Where, however, they are of large size, we invariably find other evidence of their mixture with another race. Speaking, therefore, of typical Papuans, we may say they are small, with thin limbs, and are physically weak. In their natural condition they are a savage people and are cannibals. They are broken up into hostile tribes, holding no intercourse with one another except by warfare. The languages or dialects<sup>1</sup> spoken by them are very numerous, owing, no doubt, to their hostility towards one another, which has produced complete isolation. In grammatical structure there is considerable resemblance between their languages, but owing to long isolation the verbal differences have become very great. Several different dialects are often found on one island.

Among them women hold a very low position. Nearly all the hard work falls to their share, the men devoting themselves chiefly to warfare. The women cultivate the plantations, carry the burdens, and wait on the men. They take their food from the leanings of the men. Among most of them family life is not greatly elevated above the relationships existing among the lower animals, the relations between the sexes being of the most degraded character. There is, however, considerable affection often manifested towards their children. The Papuans are impulsive and demonstrative in speech and action. They are generally a wild, noisy, boisterous people, easily pleased and as easily offended. They differ so much in different islands, however, that it is extremely difficult to generalize concerning some of their characteristics. Many of them are decidedly low intellectually. On some islands they appear to be physically and intellectually a weak and worn-out race. Yet this must not be understood as applying to all. On some islands youths and men may be seen who are among the brightest and most intelligent-looking people in the Pacific. A vast difference exists between the natives of parts of the New Hebrides and those of the Loyalty Islands, the latter being much the finer. Mixture of blood may partly account for the difference. Difference of physical surroundings, doubtless, also has something to do with it. The dry, comparatively barren, and cooler islands of the Loyalty group ought to have a finer people upon them than the malarious, hot, and moist islands of the New Hebrides. In Fiji some of the finest men in Polynesia are found, but many of the Fijians are considerably mixed with Savaiani blood.

As a rule, the Papuans lack elaborate historical traditions, poems, and songs, such as are invariably found among the Savaiani race. They do not naturally possess much religious feeling or reverence, and their religious systems are little more than fetishism. In this respect, too, they present a marked contrast to the lighter race. In arts and manufactures they are comparatively low, although there are marked exceptions. Usually their houses are very poor structures. On many islands their canoes are of inferior construction. As a race they are indifferent navigators. Their arms are, however, somewhat elaborately made; and most of them make a coarse kind of pottery. In some parts of the Solomon Islands the people build much better houses than are usually found among the Papuans, carving some of the woodwork rather elaborately. They also build good canoes or boats. In Fiji the natives build good houses and good boats, but there the people have learned some of their arts from the Savaiani. It may be so also in the Solomon group. Indeed, throughout the whole of the Papuan region, there is evidence of more or less mixture of the two races. In some places there are pure colonies of Savaiani, who keep themselves distinct from their darker-coloured neighbours; but in many other places the lighter immigrants have intermarried with the black race.

The following are some broad characteristics of the Papuan languages. Consonants are freely used, some of the consonantal sounds being difficult to represent by Roman characters. Many of the syllables are closed. There does not appear to be any difference between the definite and the indefinite article, except in Fiji. Nouns are divided into two classes, one of which takes a pronominal suffix, while the other never takes such a suffix. The principle of this division appears to be a near or remote connexion between the possessor and the thing possessed. Those things which belong to a person, as the parts of his body, &c., take the pronominal suffix; a thing possessed merely for use would not take

it. Thus, in Fijian the word *lure* means either a son or a daughter—one's own child, and it takes the possessive pronoun suffixed, as *lurena*; but the word *ngone*, a child, but not necessarily one's own child, takes the possessive pronoun before it, as *ngone ngone*, his child, i.e., his to look after or bring up.<sup>2</sup> Gender is only sexual. Many words are used indiscriminately, as nouns, adjectives, or verbs, without change; but sometimes a noun is indicated by its termination. In most of the languages there are no changes in nouns to form the plural, but an added numeral indicates number. Case is shown by particles, which precede the nouns. Adjectives follow their substantives. Pronouns are numerous, and the personal pronoun includes four numbers—singular, dual, trial, and general plural, also inclusive and exclusive. Almost any word may be made into a verb by using with it a verbal particle. The difference in the verbal particles in the different languages are very great. In the verbs there are causative, intensive or frequentative, and reciprocal forms.

II. *The Savaiani Race.*—The brown people who occupy the islands of eastern Polynesia are generally regarded as having affinities with the Malays of the Indian Archipelago, and are sometimes spoken of as a branch of the Malay race, or family. They cannot, however, with any accuracy be so described. The Malays, as they now exist, are a comparatively modern people, who have become what they are by the mixture of several elements not found in the more primitive race. The Savaiani and the Tarapona of Polynesia, the Malagasy (Hovas) of Madagascar, and the Malays are allied races, but no one of them can be regarded as the parent of the rest. The parent race has disappeared; but the Savaiani, as the earliest offshoot from it, and one which, owing to the conditions under which it has lived, has remained almost free from admixture of blood, may be taken as most nearly representing what the parent was. The relationship which these Malayo-Polynesian<sup>3</sup> races bear to one another is seen from the "tree" on Plate III.

The absence of Sanskrit (or Prakrit) roots in the languages appears to indicate that the Savaiani migration was in pre-Sanskritic times.<sup>4</sup> Whether we can fix anything like a definite date for this may well be questioned. Mr Foran<sup>5</sup> has, however, with great probability, traced back the history of the Hawaiians to the 5th century. He has studied the folk-lore of those islands exhaustively, and from this source comes to the conclusion that the Savaiani migration from the Indian Archipelago may be approximately assigned to the close of the first or to the second century. Most likely Samoa was the first group permanently occupied by them. Owing to the admixture of the Savaiani with the Papuans in Fiji some authorities have thought the first settlement was in those islands, and that the settlers were eventually driven thence by the Papuan occupiers. We can, however, account for the presence of Savaiani blood in Fiji in another way, viz., by the intercourse that has been kept up between the people of Tonga and Fiji. If the first resting-place of the Savaiani was in that group, there is good reason to believe that Samoa was the first permanent home of the race, and that from Samoa they have spread to the other islands which they now occupy.

It used to be doubted whether these people could have gone from the Indian Archipelago so far eastward, because the prevailing winds and currents are from the east. But it is now well known that at times there are westerly winds in the region over which they would have to travel, and that there would be no insuperable difficulties in the way of such a voyage. The Savaiani are invariably navigators. There is ample evidence that in early times they were much better seamen than they are at present. Indeed their skill in navigation has greatly declined since they have become known to Europeans. They used to construct decked vessels capable of carrying one or two hundred persons, with water and stores sufficient for a voyage of some weeks' duration. These vessels were made of planks well fitted and sewn together, the joints being calked and pitched.<sup>6</sup> It is only in recent times that the construction of such vessels has ceased. The people had a knowledge of the stars, of the rising and setting of the constellations at different seasons of the year. By this means they determined the favourable season for making a voyage and directed their course.

The ancestors of the Savaiani were by no means a savage people when they entered the Pacific. Indeed their elaborate historical legends show that they possessed a considerable amount of civilization. Those who are familiar with these legends, and who have studied Savaiani manners and customs, see many unmistakable proofs that they carried with them, at the time of their migration, knowledge and culture which raised them much above the status of savages, and that during their residence in these islands the

<sup>1</sup> Huxley's *Fijian Grammar*, pp. 8 and 9.

<sup>2</sup> Baron W. von Humboldt's name, Malayo-Polynesian, is here retained as a convenient term to include all these people, from Madagascar to Polynesia.

<sup>3</sup> It is possible to make too much of the absence of Sanskrit (or Prakrit) roots, as remarked by Dr Roer, "there may have been no occasion for the introduction of ready-made terms into the language." Still the migration may be tentatively put in pre-Sanskritic times.

<sup>4</sup> *The Polynesian Race*, vol. I, p. 168.

<sup>5</sup> Cocoa-butt fibre and the gum which exudes from the bread-fruit tree are generally used for "calking" and "pitching" canoes.

<sup>6</sup> No great care is here taken to distinguish between the terms languages and dialects. While all the languages of Polynesia may be included under three classes, we cannot speak of them as three languages, each with numerous dialects, any more than we could speak of those languages which have grown out of the Latin as several dialects of one language.

race has greatly deteriorated. Some indications of their former condition will appear in the following account of the people.

The Sawaioris are, physically, a very fine race. On some islands they average 5 feet 10 inches in height. De Quatrefages, in a table giving the stature of different races of men,<sup>1</sup> puts the natives of Samoa and Tonga as the largest people in the world. He gives the average height of this race as being 5 feet 9.92 inches. They are well developed in proportion to their height. Their colour is a brown, lighter or darker generally according to the amount of their exposure to the sun,—being darker on some of the atolls where the people spend much time in fishing, and among fishermen on the volcanic islands, and lighter among women, chiefs, and others less exposed than the bulk of the people. Their hair is black and straight; but in individual examples it is sometimes wavy, or shows a tendency to curl. They have very little beard. Their features are generally fairly regular; eyes invariably black, and in some persons oblique; jaws not projecting, except in a few instances; lips of medium thickness; noses generally short, but rather wide at the bases. Their foreheads are fairly high, but rather narrow. When they are young many of the people of both sexes are good-looking. The men often have more regular features than the women. In former times more attention was paid to personal appearance and adornment among men than among the women.

As a race the Sawaioris are somewhat apathetic. They differ, however, in different islands, according to their surroundings. Most of them live in an enervating climate where nature is very lavish of her gifts. Hence they lead easy lives. On the more barren islands, and on those more distant from the equator, the natives have much more energy. Under certain circumstances they become excitable, and manifest a kind of care-for-nothing spirit. This is only occasionally seen, and chiefly in time of war, in a family dispute, or on some other occasion when they are deeply moved. In the time of their heathenism they were strict in their religious observances, and religion came into almost every action of life. They were, in most instances, with comparative ease led to accept Christianity, and this characteristic has remained under the new condition of things. They are a shrewd people, with quick intelligence, and they possess naturally a large amount of common sense. Where they have from early years enjoyed the advantages of a good education, Sawaiori youths have proved themselves to possess intellectual powers of no mean order. They are almost invariably fluent speakers; with many of them oratory seems to be a natural gift; it is also carefully cultivated. A Sawaiori orator will hold the interest of his hearers for hours together at a political gathering, and in his speech he will bring in historical allusions and precedents, and will make apt quotations from ancient legends in a manner which would do credit to the best parliamentary orators. Many of them are very brave, and think little of self-sacrifice for others where duty or family honour is concerned.<sup>2</sup>

The terms for family among this race are used in two senses—(1) of a household, and (2) of all blood relations on both the male and the female side, including the wife or the husband, as the case may be, brought in by marriage,—also those who have been adopted by members of the clan. In the following remarks the word *family* is used with the first meaning, and *clan* with the second. Each clan has a name which is usually borne by one of the oldest members, who is the chief or head for the time being. This clan system no doubt generally prevailed in early times, and was the origin of the principal chieftainships. But changes have been made in most of the islands. In some the head of one clan has become king over several. In many cases large clans have been divided into sections under secondary heads, and have even been subdivided. The different classes of chieftainships may probably be thus accounted for.

As a rule, near relations do not intermarry. In some islands this rule is rigidly adhered to. There have been exceptions, however, especially in the case of high chiefs; but usually great care is taken to prevent the union of those within the prescribed limits of consanguinity. Children generally dwell with their kin on the father's side, but they have equal rights on the mother's side, and sometimes they take up their abode with their mother's family. The only names used to express particular relationships are father and mother, son and daughter, brother and sister.

<sup>1</sup> *The Human Species* (International Scientific Series), pp. 57-60.

<sup>2</sup> Of various acts by Sawaioris which indicate the possession of bravery and self-possession under trying circumstances the following may serve as a sample. Some lads belonging to two villages in Samoa fell out, and began stone-throwing. One of them, who was the son of a chief, was struck and, it was feared, was killed. As soon as this was known to the young men of the village they armed themselves in order to go to the other village to seek reparation, according to a custom of former times, by killing some one belonging to the family of the boy who had thrown the stone. A report preceded them that they were going, and a young man, a cousin of the boy, in order to prevent a fight, quietly walked out of the village to meet the avengers of blood. When he met them he calmly said, "You do not go further; kill me and be avenged, so that our villages may remain at peace." His conduct somewhat disconcerted the party, and by the timely arrival of a Christian teacher matters were settled without bloodshed.

There is usually no distinction between brothers (or sisters) and cousins, all the children of brothers and sisters speak of each other as brothers and sisters, and they call uncles and aunts fathers and mothers. Above the relationship of parents all are simply ancestors, no term being used for grandfather which would not equally apply to any more remote male ancestor. In the same way there is no distinctive term for grandchild. A man speaks of his grandchild as his son or daughter, or simply as his child.<sup>3</sup> Polygamy was often practised, especially by chiefs, and also concubinage. In some places a widow was taken by the brother of her deceased husband, or, failing the brother, by some other relative of the deceased, as an additional wife. Divorce was an easy matter, and of frequent occurrence; but, as a rule, a divorced wife would not marry again without the consent of her former husband. An adulterer was always liable to be killed by the aggrieved husband, or by some member of his clan. If the culprit himself could not be reached, any member of the clan was liable to suffer in his stead. In some islands female virtue was highly regarded. Perhaps of all the groups Samoa stood highest in this respect. There was a special ordeal through which a bride passed to prove her virginity, and a proof of her immorality brought disgrace upon all her relatives. But in other islands there was much freedom in the relations of the sexes. Owing to the almost promiscuous intercourse which prevailed among a portion of the race, in some groups titles descended through the mother and not through the father. In Hawaii there was a peculiar system of marriage relationship, "brothers with their wives, and sisters with their husbands, possessing each other in common." There also, especially in the case of chiefs and chieftainesses, brothers and sisters sometimes intermarried. But these customs did not prevail in other groups. It is almost certain that they did not prevail in Hawaii in early times, but that they were the result of that deterioration in the race which their traditions and many of their customs indicate.<sup>4</sup>

Women have always occupied a relatively high position among the Sawaioris. In most groups they have great influence and are treated with much respect. In some cases they take hereditary titles and hold high offices. As among their congeners in Madagascar, so also in parts of Polynesia, there may be a queen or a chieftainess in her own right; and a woman in high position will command as much respect, and will exercise as great authority, as a man would in the same position. Everywhere infanticide prevailed; in some of the smaller islands it was regulated by law in order to prevent over-population. It was also a very common practice to destroy the fetus, yet, even before the reception of Christianity, parents were affectionate towards the children who were spared. The practice of adopting children was, and still is, common. Often there is an exchange made between members of the same clan; but sometimes there is adoption from without. Tattooing generally prevailed among the men, different patterns being followed in different groups of islands. In some a larger portion of the body is tattooed than in others. A youth was considered to be in his minority until he was tattooed, and in former times he would have no chance of marrying until he had, by submitting to this process, proved himself to be a man. Puberty in the other sex was generally marked by feasting, or some other demonstration, among the female friends. Old age is generally honoured. Often an inferior chief will give up his title to a younger man, yet he himself will lose but little by so doing. The neglect of aged persons is extremely rare.

Property belonging to a clan is held in common. Each clan usually possesses land, and over this no one member has an exclusive right, but all have an equal right to use it. The chief or recognized head of the clan or section alone can properly dispose of it or assign its use for a time to an outsider; and even he is expected to obtain the consent of the heads of families before he alienates the property. Thus land is handed down through successive generations

<sup>3</sup> Dr Lewis H. Morgan in *Ancient Society*, pp. 419-423, makes the Sawaioris to have distinctive terms for grandfather, grandmother, grandson, and granddaughter. In this he is entirely mistaken. It is evident from his own lists that the Hawaiian *kypuna* means simply an ancestor. In like manner *moopuna* simply means a descendant of any generation after the first.

<sup>4</sup> Morgan has founded one of his forms of family—the consanguine—on the supposed existence in former times among the Malays and Polynesians of the custom of "intermarriage of brothers and sisters, own and collateral, in a group." All the evidence he finds in support of this is (1) the existence of the custom above mentioned in Hawaii, and (2) the absence of special terms for the relationship of uncle, aunt, and cousin, this indicating, he thinks, that these were regarded as fathers, mothers, brothers, and sisters. He admits that "the usages with respect to marriage which prevailed when the system was formed may not prevail at the present time." But he adds, "To sustain the deduction it is not necessary that they should" (*Ancient Society*, p. 408). Morgan has given special terms for grandfather and grandmother, because it would prove too much to show that the people had no grandfathers, &c. But these terms are used for ancestors of any generation. The terms used for grandchildren, in like manner, are used for any generation of descendants. He says (p. 406) the terms of husband and wife are used in common by a group of sisters or brothers, but the fact is that the words used for husband and wife in Hawaii simply mean male and female. In some islands there are terms used for wife in the most strict sense. The word wife is not used more exclusively among us than among some Sawaiori people.

under the nominal control of the recognized head of the clan or section for the time being. Changes have been made in many islands in this respect; but there can be little reason to doubt that the joint ownership of property in clans was common among the entire race in former times.

In early times the head of each clan was supreme among his own people, but in all matters he had associated with him the principal men or heads of families in the clan. Their united authority extended over all the members and the possessions of the clan, and they were independent of every other clan. There are in some places vestiges of this primitive state of society still remaining; the transition to a limited or to a despotic monarchy may be traced by means of the ancient legends in some islands, and in others it is a matter of recent history. One clan being more numerous and stronger than another, and its chief being ambitious, it is easy to see how by conquering a neighbouring clan he increased the importance of his clan and extended his own power. In some of the islands this transition process has hardly yet developed into an absolute monarchy. We may even see two or three stages of the progress. In one instance a certain clan has the right to nominate the principal chief over an entire district; though it is known as the ruling clan, its rule is mainly confined to this nomination, and to decision for or against war. In all other respects the district enjoys the privilege of self-government. In another case the nominal king over a district, or over an entire island, can be elected only from among the members of a certain clan, the monarchy being elective within that alone; but this king has little authority. In other cases a more despotic monarchy has grown up—the process of one man leading to the subjugation of other clans. Even in this case the chiefs or heads of clans sometimes still hold their property and rule over their own people, only rendering a kind of feudal service and paying tribute to the king.

The Sawaioris are exceedingly fond of rank and of titles. Much deference is paid to chiefs and to persons of rank; and special terms are generally employed in addressing these. Every part of a chief's body and all his belongings have names different from those employed for common people. The grade of rank which a person occupies will often be indicated by the language in which he is addressed. Thus, in Samoa there are four different terms for to come:—*tau* is for a common man; *malu mai* is a respectful term for a person without a title; *susu mai* for a titled chief; and *afu mai* for a member of the royal family. In addressing chiefs, or others to whom one wishes to be respectful, the singular number of the personal pronoun is rarely used; the dual is employed instead,—the dual of dignity or of respect.

Officers and titles are seldom hereditary in our sense of the term, as descending from father to son. They are rather elective within the limits of the clan, or the division of a clan. A common practice is for the holder of a high title to nominate a successor; and his nomination is generally confirmed by the chiefs, or heads of households, with whom the right of election rests. In ancient times the authority of a high chief or king did not usually extend to any details of government. But in Hawaii there are traditions of a wise king who interested himself in promoting the social well-being of the people, and made good laws for their guidance.<sup>1</sup> Usually all matters affecting a district or an island were settled by the chiefs of the district, while those of a single village were settled by a council consisting of the chiefs and heads of households in the village. In some islands each clan, or each village, would feel itself at liberty to make war on another clan or village, without consulting the views of any higher authority. Indeed the rule was for each clan or district to settle its own affairs. In the case of offences against individuals, either the person injured, or another member of his clan, would avenge the injury done. For most offences there was some generally recognized punishment—such as death for murder or adultery; but often vengeance would fall upon another person instead of the wrongdoer. In avenging wrong, a member of the village or of the clan to which the offender belonged would serve equally well to satisfy their ideas of justice if the culprit himself could not be easily reached. Sometimes all the members of the family, or of a village, to which a culprit belonged would flee from their houses and take refuge in another village, or seek the protection of a powerful chief. In some places, in cases of crime, the members of the family or village would convey the culprit bound—sometimes even carrying him like a pig that is to be killed—and place him with apologies before those against whom he had transgressed. The ignominy of such a proceeding was generally considered sufficient atonement for the gravest offences. There were slaves in many islands, either persons conquered in war, or those who had been condemned to lose their personal liberty on account of evil conduct.

Pottery was not manufactured by the Sawaioris. When any of them possessed it they obtained it from the Papuans. In most of their manufactures they were, however, in advance of the Papuans. They made use of the vegetable fibres abounding in the islands, the

women manufacturing cloth, chiefly from the bark of the paper mulberry (*Morus papyrifera*), but also in some islands from the bark of the bread-fruit tree, and the hibiscus. This in former times furnished them with most of their clothing. They also made various kinds of mats, baskets, and fans from the leaves of the pandanus, the bark of the hibiscus, from species of böhmeria or other Urticaceous plants. Some of their mats are very beautifully made, and in some islands they are the most valuable property the people possess. The people also use the various fibre-producing plants for the manufacture of ropes, coarse string, and fine cord, and for making fishing nets. The nets are often very large, and are netted with a needle and mesh as in hand-netting among ourselves. The Sawaioris are rather clever workers in wood. Canoe and house-building are trades usually confined to certain families. The large canoes in which they formerly made long voyages are no longer built, but various kinds of smaller canoes are made, from the commonest, which is simply a hollowed-out tree cut into form, to the finely-shaped one built upon a keel, the joints of the various pieces being nicely fitted, and the whole stitched together with cord made from the husk of cocoa-nuts. Some of the larger canoes are ornamented with rude carving; and in some islands they are somewhat elaborately decorated with inlaid mother of pearl. The houses are generally well and elaborately made, but nearly all the ornamentation is put on the inside of the roof. The Sawaioris manufacture several wooden utensils for household use, such as dishes or deep bowls, "pillows" or head-rests, and stools. They also make wooden gongs, or drums, which they beat as they travel in their boats, in their dances, &c. They used to make wooden fishhooks, clubs, spears, and bows. They still make wooden fish-spears; also carved and inlaid combs. They employ the bamboo for making drums and flutes. Formerly the knives the people used were made of bamboo, which is still sometimes used for that purpose. In the manufacture of these things they employed adzes made of stone, shell, or hard wood, and a wooden drill pointed with stone, shell, or bone. They made mother-of-pearl fishhooks, and they still use a part of those old hooks—or artificial bait—in combination with steel hooks, the native-made portion being generally shaped like a small fish. For water vessels, &c., they employ gourds and large cocoa-nut shells, in preparing which they put water into them and allow the pulp or the kernel to decay, so that it may be removed without breaking the rind or shell. Their drinking cups are made of half a cocoa-nut shell. Sharks' teeth, shells, and bamboo were formerly generally used as cutting instruments; shaving was done with them, as well as surgical operations. They employ vegetable dyes for painting their bark cloth, calabashes, &c. In some islands they also use a red earth for this purpose. Their cloth is generally ornamented with geometrical patterns. Any drawings of animals, &c., which they make are exceedingly unartistic, and no attempt is made at perspective. Their musical instruments are few and rude—consisting of the drums and flutes already mentioned, and shell trumpets.

The Sawaioris were all polytheists. Without doubt many of their gods are deified men; but it is clear that some are the forces of nature personified, while others appear to represent human passions which have become identified with particular persons who have an existence in their historical myths.<sup>2</sup> But the conception which they had of Tangaloa (Taaroa and Kavaloa in some islands) is of a higher order. Among the Tahitians he was regarded as "the first and principal god, uncreated, and existing from the beginning, or from the time he emerged from *po*, or the world of darkness."<sup>3</sup> "He was said to be the father of all the gods, and creator of all things, yet was scarcely reckoned an object of worship."<sup>4</sup> Dr Turner says, "the unrestricted, or unconditional, may fairly be regarded as the name of this Samoan Jupiter."<sup>5</sup>

The worship of certain of the great gods was common to all the people in a group of islands. Others were gods of villages or of families, while others were gods of individuals. The gods of clans were probably the spirits of the ancestors in their own line. In some islands, when the birth of a child was expected, the aid of the gods of the family was invoked, beginning with the god of the father. The god prayed to at the instant of birth became the god of the child. In other places the name of the child's god was declared when the umbilical cord was severed. The gods were supposed to dwell in various animals, in trees, or even in inanimate objects, as a stone, a shell, &c. In some islands idols bearing more or less resemblance to the human shape were made. But in all cases the material objects were regarded simply as the abodes of the immaterial spirits of the gods.

Their temples were either national, for a single village, or for the god of a family. They were sometimes large stone enclosures (*marae*), sometimes a grove, or a house. The principal priests were a particular order, the priesthood being hereditary. In some cases,

<sup>1</sup> The following recent books may be consulted on this subject:—Rev. W. W. Gill's *Myths and Songs from the South Pacific*; Dr Turner's *Samoa*; and Mr. Shortland's *Maori Religion and Mythology*.

<sup>5</sup> XIX. — 54

<sup>1</sup> See a remarkable example in Forster's *Polynesian Race*, vol. II. p. 89.

however, the father of a family was priest in his own household and presented offerings and prayers to the family god.

There was, in the Society Islands, a privileged class known as the *Areoi*. They were the special devotees of two celibate gods. They were not permitted to have children; any children they possessed when they entered the society, and all children subsequently born to them, were destroyed. The name *Areoi* became the synonym for all kinds of licence; the party wandered about from place to place conducting obscene entertainments, and was feasted with the best of all the people possessed. There were seven regular grades among the *Areoi* society, besides an irregular class of attendants.

In some islands human sacrifices were of frequent occurrence; in others they were offered only on very rare and exceptional occasions, when the demand was made by the priests for something specially valuable. The usual offerings to the gods were food. The system of *tapu* or *tabu* so common among the Sawaioris was connected with their religious rites. There were two ways by which things might become *tapu*,—(1) by contact with anything belonging to the god, as his visible representation or his priest. Probably it was thought that a portion of the sacred essence of the god, or of a sacred person, was directly communicable to objects which they touched. (2) Things were made *tapu* by being dedicated to the god; and it is this form of *tapu* which is still kept up. If, e.g., any one wishes to preserve his cocoa-nuts from being taken, he will put something upon the trees to indicate that they are sacred or dedicated. They cannot then be used until the *tapu* is removed from them. Disease and death were often connected with the violation of *tapu*, the offended gods thus punishing the offenders. Disease was generally attributed to the anger of the gods. Hence offerings, &c., were made to appease their anger. The first-fruits of a crop were usually dedicated to the gods to prevent them from being angry; and new canoes, fishing-nets, &c., were dedicated by prayers and offerings, in order that the gods might be propitious to their owners in their use.

The Sawaiori people invariably believe in the existence of the spirit of man after the death of the body. Their traditions on the condition of the dead vary considerably in different groups; yet there is a general agreement upon main points. Death is caused by the departure of the spirit from the body. The region of the dead is subterranean. When the spirit leaves the body it is conveyed by waiting spirits to the abode of spirits. In most islands the place of descent is known. It is generally towards the west. In some traditions there is a distinction between chiefs and common people in the spirit world. In others all are much alike in condition. Some traditions indicate a marked distinction between the spirits of warriors and those of others: the former go to a place where they are happy and are immortal, while the latter are devoured by the gods and are annihilated. In some, however, the spirits are said to live again after being eaten. Some speak of the abode of spirits as being in darkness; but usually the condition of things is similar to that which exists upon earth. Amongst all the people it is believed that the spirits of the dead are able to revisit the scenes of their earthly life. The visits are generally made in the night, and are often greatly dreaded, especially when there may be any supposed reason for spite on the part of the dead towards living relatives. Some writers have connected cannibalism, where it existed among the Sawaioris, with religious customs. In the Cook and Society Islands, when a human being was offered as a sacrifice, the priest presented an eye of the victim to the king, who either ate it or pretended to do so. Probably the earliest human sacrifices were the bodies of enemies slain in battle. As it was supposed by some that the spirits of the dead were eaten by the gods, the bodies of those slain in battle may have been eaten by their victors in triumph. Mr Shortland appears to think that cannibalism among the Maories of New Zealand may have thus originated.<sup>1</sup> Among the Sawaioris generally it appears to have been the practice at times to eat a portion of a slain enemy to make his degradation the greater. In several groups there is evidence that this was done. But where cannibalism was practised as a means of subsistence, it probably originated in times of actual want, such as may have occurred during the long voyages of the people, when it was resorted to as a means of self-preservation. Being once accustomed to the practice, we can easily imagine how they might resort to it again and again in times of scarcity. The testimony of cannibals is that human flesh is the best of food, and among such a people there would not be strong moral reasons to restrain them from the indulgence.

The amusements of these people are very numerous. They are a light-hearted race, usually living under easy conditions of life, and they have a large amount of enjoyment. Some of their amusements are boisterous and even savage, such as wrestling and boxing. In some islands they have a kind of "hockey" and football. They have running races, walking matches, and canoe-racing. One of their most exciting amusements is swimming in the surf. When there is a moderate sea on, great numbers often join in this exercise and find immense pleasure in it. Throwing the javelin, throwing at a mark with slings, and archery are

also practised. Some resort to cock-fighting. There are fishing matches; and at a particular season large companies used to resort to pigeon-catching. In their houses they have a number of games. Betting is very often carried on in connexion with these. Much time is spent, especially after the evening meal, in asking riddles, in rhyming, &c. The recital of songs and myths is also a source of great amusement; and on special occasions there is dancing. The night dances were generally accompanied by much indecency and immorality, and for that reason were discountenanced on the introduction of Christianity.

III. *The Tarapona Race*.—These people have many points of resemblance to the Sawaioris, but, as a rule, they are of smaller stature and are less robust. They have straight black hair, which is more lank than that of the Sawaioris. The Tarapona, however, differ considerably from one another, and are evidently a mixed race. The natives of the Caroline Islands are larger than the Gilbert Islanders. They are also much lighter in colour; they are more yellow, whereas the Gilbert Islanders are darker, than the Sawaioris. In many respects the Tarapona bear a much closer resemblance to the people of some portions of the Indian Archipelago than do the Sawaioris. It is the belief of the present writer that the bulk of the Tarapona are the descendants of people who, in comparatively recent times, migrated from the Indian Archipelago, and that since they have been in Polynesia they have become mixed with people of other races. There appears to be a little Papuan admixture. Those in the Caroline Islands, especially, appear to have become mixed with Chinese and Japanese blood—probably more Japanese than Chinese. There are several well-authenticated instances of Japanese junks, with living people in them, having been found in various parts of the North Pacific. In 1814 the British brig "Forester" met with one off the coast of California (about 30° N. lat.), with three living men and fourteen dead bodies on board. In December 1832 a Japanese junk arrived at the Hawaiian Islands with four of the crew living. If these junks could cross the Pacific in the latitude of Hawaii it is not at all unlikely that others running in a south-easterly direction would reach some of the many atolls which stretch over about 35° of longitude, forming the Caroline and Marshall archipelagoes.

The traditions of the Gilbert Islanders tell us that their islands were peopled from the west and also from the east. Those who came from the east are expressly said to be from Samoa. Those from the west were more numerous than those from the east. There are also traditions of the arrival of other strangers at some of these islands. When the present writer was at the island of Peru, in the Gilbert group, in 1869 there was still there the remnants of a large proah which, from the description given, appears to have been like those used in the Indian Archipelago. So far as we have materials for examination, craniometry confirms other evidence, and indicates that the Tarapona people are more mixed than either of the other Polynesian races.

All the Tarapona people are navigators, but, owing to the fact that upon their atolls they have little good timber, most of their canoes are inferior to those of the Sawaioris. Their houses are also inferior. Their arms are fairly well made. In the Gilbert Islands they manufacture elaborate armour, to cover the entire body, from the fibre of the cocoa-nut husk. In the Caroline Islands very fine mats are made; and a hand-loom is used, with which a coarse cloth is made.

Among the Tarapona women occupy a lower position than among the Sawaioris. The difference is not, however, in the amount of work, or kind of drudgery, that is expected from them, but rather in the social and domestic influence they exert. The gods are chiefly the spirits of the great men of past ages. The chieftainship and priesthood are often combined in the same persons. They are strict in the observance of their religious rites. The shrines of their gods are very numerous. In every house he visited in the Gilbert Islands, the present writer saw either a small circle or a square formed with pieces of coral or shells; this was neatly covered with broken coral and shells from the beach, and in the centre stood a block of coral representing the god. These were the household shrines. In various places about the islands there were similar squares or circles, only larger, for the gods of villages or districts. Offerings of food were presented to them, and often the stones were garlanded with wreaths of cocoa-nut leaves. Some embalm their dead—especially the bodies of beloved children. Women often carry the skulls of deceased children, hung by a cord around the neck, as a token of affection.

In the Tarapona languages consonants are more freely used than in the Sawaiori. They have consonantal sounds which are not found in the latter, such as *ch*, *dj*, and *sh*. Closed syllables often occur; occasionally doubled consonants are used, but among some of the people there is a tendency to introduce a slight vowel sound between them. Most words take the accent on the penult. In some languages there appears to be no true article; but in the Gilbert Island language the Sawaiori *te* is used for both the definite and the indefinite article. Gender is sexual only. Number in the noun is either gathered from the requirement of the sense, or is marked by pronominal words, or numerals. Case is known by the

<sup>1</sup> *Maori Religion and Mythology*, p. 26.

position of the noun in the sentence, or by prepositions. In the language of Ebon, one of the islands in the Marshall archipelago, nouns have the peculiarity which is characteristic of the Papuan languages: those which indicate close relationship—as of a son to a father, or of the members of a person's body—take a pronominal suffix which gives them the appearance of inflexions. The present writer is not aware of the existence of this in any other Tarapou language, but would not make too much of this negative evidence. Many words are used indiscriminately as nouns, adjectives, or verbs without any change of form. In some languages the personal pronouns are singular, dual, and plural. In others there are no special dual forms, but the numeral for two is used to indicate the dual. In the Ebon language there are inclusive and exclusive forms of the personal pronouns which, so far as has been ascertained, do not occur in any of the other Tarapou languages. The verbs usually have no inflexions to express relations of voice, mood, tense, number of person,—such distinctions being indicated by particles. In the Ebon language, however, the tenses are sometimes marked; but in that the simple form of the verb is frequently given. All have verbal directive particles. In Ponape, one of the Caroline Islands, many words of ceremony are used in addressing chiefs, as they are used in Samoa. The custom of tabooing words is also found there as it is in the Savaiani languages. For further particulars respecting the Tarapous, see MICRONESIA.

**Missions.**—The first mission was commenced in Tahiti by the agents of the London Missionary Society in 1797. Since then that society has continued and extended its labours until it now occupies the Society, Cook, Austral, Tuamotu, Samoan, Tokelauan, and Ellice groups, and several isolated islands, all peopled by the Savaiani race, besides other islands in the Papuan and Tarapou areas. With the exception of a portion of the Tuamotu archipelago, all the people in the groups mentioned are now nominal Christians. There are only three groups peopled by the Savaianis where the London Missionary Society's agents do not labour; and two of these are efficiently occupied by other societies—Hawaii mainly by the American Board, and Tonga by the Wesleyan Missionary Society. These two groups are also entirely Christian. The Marquesas Islands have not been Christianized, but are partly occupied by missionaries from Hawaii. There are, therefore, only two groups peopled by the Savaianis where any heathen are found at the present day. An estimate of the number of this people, based upon actual counting in many islands, would be about 174,000, of which number about 151,500 are nominal Christians, leaving about 22,500 still heathen. Of the Papuans a smaller proportion are Christians. In Fiji and Rotuma the great majority of the population have become nominal Christians through the labours of Wesleyan missionaries. The Wesleyans have also successfully laboured in Duke of York Island, near New Britain. In the Loyalty Islands most of the people have embraced Christianity through the labours of the London Missionary Society's agents,—a part, however, being Roman Catholics. Anstrutium in the New Hebrides has become wholly Christian through the agency of Presbyterian missions. In a few other islands in the New Hebrides, also in Banks and Santa Cruz groups, small companies of converts have been gathered by the Presbyterian and the Episcopal (Melanesian) missions. The rest of the people in the Papuan area in Polynesia are still savages, and most of them are cannibals. The population of this area may be estimated at about 200,000. Of this number about 130,000 are nominal Christians. Excluding the inhabitants of the Ladrone and Pelew Islands, the Tarapou people may be estimated at about 84,000. The agents of the Hawaiian Board of Missions (taking the place of the American Board, under whose auspices the missionaries first laboured in this region) are the most numerous here, occupying portions of the Gilbert, Marshall, and Caroline Islands. Six atolls south of the equator in the Gilbert group are occupied by native missionaries from Samoa in connexion with the London Missionary Society. The number of nominal Christians in these groups is about 38,000. The aggregate population of Polynesia may thus be estimated at 533,000, of whom 539,500 are heathen and 323,500 are nominal or baptized Christians. From the records of the various missionary societies it appears that out of this number 62,605, or very nearly one-fifth, are communicants.

In addition to the missionary societies already mentioned, which have done the main work in the evangelization of the Polynesians, there are French Protestant missionaries in Tahiti, and Protestant Episcopal clergymen in Hawaii and in Fiji. There are also in many islands French Roman Catholic missionaries; but these have a comparatively small number of adherents.

Wherever the missions have been planted, schools have also been established, and the people have received more or less education. On the Christian islands nearly all the people can now read, most can write, and a large proportion are acquainted with the elements of arithmetic. General education, thus far, is much more common on these islands than it is at present in the British Isles. Advanced schools have been founded in connexion with some of the missions, and many of the native youths have shown considerable aptitude

for some of the higher branches of knowledge. In most of the larger groups colleges for the education of native ministers have long been conducted. In these colleges, in addition to Biblical exegesis and theology, other subjects, such as history and elementary science, are taught. Many of the European and American missionaries have devoted themselves largely to literary work in the vernacular of the islands where they reside. Next to the translation of the Scriptures and the preparation of lesson books for the common schools, they have either translated works on history, science, &c., or they have written such books as they found the natives to need. In nearly every group occupied by the Savaiani race there is now a considerable vernacular literature, embracing elementary works on most branches of knowledge. Amongst the other races the literature is of much smaller extent. The entire Bible has been translated into five of the principal Savaiani languages of Polynesia. The entire New Testament, and a considerable portion of the Old, has been translated into a sixth language, besides smaller portions into others. The American Bible Society has supplied the Bibles for the Hawaiian Islands. Many portions of the Scriptures for other islands have been printed either in the islands or in Australia. Of the number of copies thus circulated no record is easily accessible, but the British and Foreign Bible Society has issued 153,452 entire Bibles or New Testaments in the Samoan, Tahitian, Tongan, Rarotongan, and Niuean languages. As among this race one translation serves for an entire group, and in some cases for two or three groups, nearly all the people possess the Scriptures. In no part of the world is the Bible more read than it is by these islanders; and it has not been necessary to give the Scriptures to them without charge in order to induce them to read.

In many islands the pastoral work is now mostly done by native ministers,—the foreign missionaries who remain devoting themselves to superintendence, higher education, and literature. The native pastors are always supported by the voluntary gifts of the people to whom they minister. The people also build their own churches and schools, and meet all the expenses connected with public worship and education, upon the voluntary principle. No portion of Christendom is better supplied with religious instruction than the Christianized islands of Polynesia, and nowhere is there more regard paid by the people generally to Sabbath observance, to public worship, and to other outward duties of religion. Family worship is almost invariably observed.

With all this, too many of the people are religious only in name: and in the neighbourhood of ports, where casual visitors usually see and judge the native character, there are some who have added many of the white man's vices to their own. But in estimating the influence of Christianity upon these people we should remember that only about one-fifth of the nominal Christians are communicants. If they be judged fairly, taking into consideration their past history and the short time they have been under Christian influence, the present writer is convinced that the verdict will be favourable as compared with any Christian people in the world. Every one will admit that social, moral, and spiritual reformation are not completed in a generation, but require time to bring them to maturity.

**Population—its alleged decrease.**—There is a general notion abroad that in all the islands of Polynesia the native races are rapidly decreasing; and this supposed fact is sometimes attributed to the missionaries. The alleged diminution, however, is a general conclusion from particular premises, and facts drawn from wider observations do not confirm it. The question of the decrease of population in these islands is a wide one, which cannot be fully discussed within the limits of the present article; but a few general observations, and a few particular facts, may help to throw some light upon it. (1) The estimates of population made by the first European or American visitors to Polynesia were far too high. In nearly all islands the people live almost entirely upon the coast: hence it was an error to reckon the inland portions as having a population proportionate to the number of people seen upon the coast. Then, when the visits of foreign ships were a novelty, the people from other districts would crowd to the place where the ships anchored to see them. Thus the population of particular villages was over-estimated. In the last edition of this *Encyclopædia* the population of Samoa is said to be variously estimated at from 160,000 to as few as 38,000. It is now known that even the lowest estimate was somewhat over the actual number.<sup>1</sup> Most of the other groups were also greatly over-estimated. Hence the decrease of population in any of the islands since they have become known is not so great as it is supposed to be. (2) Those who have resided in Polynesia, and who have made observations on the subject, know that previous to the introduction of Christianity there had been a great decrease in the population of most of the islands. There are numerous evidences that they were formerly much more

<sup>1</sup> In *Nature*, for 1876, vol. xiv. pp. 15-20, Mr. Wallace gave the latest census of Samoa, taken by actual counting, as being 24,000 in 1874. Yet in his *Islands of the Pacific*, published in 1873, Mr. A. R. Wallace says the population of these islands "is variously estimated at 25,000 or 60,000."

thickly peopled. Wars, infanticide, human sacrifices, and cannibalism are doubtless among the causes of depopulation. (3) Where the scourge of syphilis had not spread before Christianity was received, and the love of ardent spirits has not corrupted the people, there the population has generally increased. It is found from a record of births and deaths in some parts of Samoa, and from periodical census returns as a result of actual counting from the whole of that group, that, apart from the destruction caused by war, the population there increases at the rate of about 1 per cent. per annum. Although Samoa has suffered more from internecine wars than any other Christian group in Polynesia, there are more natives now living there than when they were first counted in 1843, the number then being 33,901. The increase in Tonga has been 25 per cent. in twenty years.<sup>1</sup> On the island of Niue the increase is more than 3 per cent. per annum. On several other groups there has been increase, though figures are not available. The rapid decline of population in Hawaii is entirely exceptional.

**Commerce.**—Information on this subject, as far as it is available, is given in the special articles on particular groups. The following is a fair specimen of the kind and extent of the commerce which has grown in Polynesia since Christianity has made the islands safe and profitable places for the residence of traders.<sup>2</sup> From Cook Islands, containing a population of about 8000, and three atolls which lie north of that group, viz., Tongareva, Rakaanga, and Manihiki, with a population of about 4000, the exports during 1883 were 150 tons of cotton free from seeds, 50 tons of coffee, 1000 tons of copra, 84 tons of pearl shell, and about 100,000 gallons of lime juice, besides 5000 crates of oranges, containing about 300 per crate. Mr Gill estimates the market value of this produce at £50,000,—more than £4 per head for the native population. Part is purchased by merchants in Tahiti, and part goes to Auckland, New Zealand. There are not many islands whence fruit is exported, although, if there were markets within a few days' sail, a large quantity of fine oranges, pine-apples, and bananas might be provided. In 1878 the figures collected by the present writer relating to the trade in Samoa, Tonga, and several other islands in that neighbourhood, showed that the exports averaged annually about £4 each for the entire population, and that the imports were only a little less.

**Prehistoric Remains.**—The most remarkable of these are on Easter Island, which lies at the south-eastern extremity of Polynesia, nearly 2500 miles from South America. This island is of volcanic formation, and is about 11 miles long by 4 miles wide. The present inhabitants belong to the Sawaiori race. Here are found immense platforms built of large cut stones fitted together without cement. They are generally built upon headlands, and on the slope towards the sea. The walls on the sea-side are, in some of the platforms, nearly 30 feet high and from 200 to 300 feet long, by about 30 feet wide. Some of the squared stones are as much as 6 feet long. On the land side of the platforms there is a broad terrace with large stone pedestals upon which once stood colossal stone images carved somewhat into the shape of the human trunk. On some of the platforms there are upwards of a dozen images now thrown from their pedestals and lying in all directions. Their usual height is from 14 to 16 feet, but the largest are 37 feet, while some are only about 4 feet. They are formed from a grey trachytic lava found at the east end of the island. The top of the heads of the images is cut flat to receive round crowns made of a reddish vesicular tuff found at a crater about 8 miles distant from the quarry where the images were cut. A number of these crowns still lie at the crater apparently ready for removal, some of the largest being over 10 feet in diameter. In the atlas illustrating the voyage of La Pérouse a plan of the island is given, with the position of several of the platforms. Two of the images are also represented in a plate. One statue, 8 feet in height and weighing 4 tons, was brought to England, and is now in the British Museum. In one part of the island are the remains of stone houses nearly 100 feet long by about 20 feet wide. These are built in courses of large flat stones fitted together without cement, the walls being about 5 feet thick and over 5 feet high. They are lined on the inside with upright slabs, on which are painted geometrical figures and representations of animals. The roofs are formed by placing slabs so that each course overlaps the lower one until the opening becomes about 5 feet wide, when it is covered with flat slabs reaching from one side to the other. The lava rocks near the houses are carved into the resemblance of various animals and human faces, forming, probably, a kind of picture writing. Wooden tablets covered with various signs and figures have also been found. The only ancient implement discovered on the island is a kind of stone chisel, but it seems impossible that such large and numerous works could have been executed with such a tool. The present inhabitants of Easter Island know nothing of the construction of these remarkable works; and the entire subject of their existence in this small and remote island is a mystery.

On the island of Tonga-tabu, Tonga group, there is a remarkable monument. Two large rectangular blocks of stone, about 40 feet in height, stand perpendicularly, with a large slab lying across from one to the other. On the centre of the horizontal stone is a large stone bowl. The island upon which this monument is found is of coral formation slightly elevated. These immense stones must therefore have been conveyed thither by sea. The present inhabitants know nothing of their history, or of the object which they were intended to serve.

In Ponapé, one of the islands of the Caroline group, there are extensive ruins, the principal being a court about 300 feet in length, the walls of which are formed of basaltic prisms and are about 30 feet in height. Inside, on all four sides, next the wall is a terrace 8 feet high and 12 feet wide. The court is divided into three by low walls, and in the centre of each division there is a covered chamber 14 feet square. The walls above the terrace are 8 feet thick, and some of the stones are 25 feet long by 8 feet in circumference. The basaltic columns of which this structure is built were apparently brought a distance of 10 miles from the central ridge of the island. There are other ruins of smaller extent on Ponapé, and also on the island of Kusaie in the same group. Ponapé and Kusaie are remnants of larger islands which have been partially submerged. While the smaller islands around which the coral polypes built up the atolls have disappeared, these two remain as monuments of the past.

North-west from Ponapé, in the Mariana or Ladrone Islands, there are other remains in the shape of stone columns about 14 feet high, with a semi-globular stone nearly 6 feet in diameter on the top of each, the rounded side being uppermost.

Thus in four different and widely separated parts of Polynesia there are relics of prehistoric people. These together form one of the greatest puzzles the ethnologist has to deal with. (S. J. W.)

**POLYPE.** In its Greek and Latin forms the word *polypus* was first used as descriptive of the CUTTLE-FISH (*q.v.*). In speaking of the *Acalephæ* Aristotle says, "They hold their prey as the polypus does with its feelers," and there is no doubt that in this and other passages he referred to the octopus. The word was also, though less generally, applied to the woodlouse (*Oniscus*)—the reason for both usages being equally evident. Though the former meaning persists in the word *poulpe*, yet by the beginning of the 18th century it seems to have been forgotten, and the word was by analogy transferred to a group of animals then beginning to attract much attention. Réaumur and Bernard de Jussieu were the first to fix the usage of the word polype as applicable to hydroids, corals, and *Polyzoa*. In following up the discoveries of Marsigli and Peysonelle in regard to the little coral organisms, Jussieu used the name polype definitely to describe those Sertularians, Alcyonians, sea-mats, &c., which were then (1742) known as animals. Trembley had previously rediscovered Leeuwenhoek's *Hydra*, and described it as a freshwater polype in a work which appeared in 1744. A polyzoon too, discovered both by Trembley and Baker in 1741, was called by the former *Polype à Panache*. We find the word used with the same content as Jussieu had assigned to it by Ellis in 1755, by Cavolini in 1783, and by others. In 1816 Lamouroux published his *Histoire des Polypiers Coralligènes*, in the preface of which he speaks of the varied character of this group of animals "nommés Hydres par Linné et Polypes par Réaumur." In his own use of the term he applied it to sponges, hydroids, corals, and *Flustra*. Lamarck too used the word very widely, and spoke of *Polypei* as (1) *ciliati*, including some Infusorians and Rotifers; (2) *denuclati*, including *Hydra*, *Coryne*, &c.; (3) *vaginati*, including *Diffugia*, *Spongilla*, *Tubularia*, Millepores and Madreporae, *Alcyonia*, *Cristatella*, *Flustra*, &c.; and (4) *natantes*, including *Pennatula*, *Virgularia*, *Encrinurus*, &c. Sometimes, however, he used the word in a more restricted sense. Cuvier (1819–1830) distinguished three classes of polypes:—(1) fleshy—*Actinia* and *Lucernaria*; (2) gelatinous—*Hydra*, *Cristatella*, *Coryne*, *Vorticella*, &c.; and (3) *Corallifera*—Sponges, Madreporae, Millepores, *Tubularia*, *Sertularia*, *Alcyonidae*, *Flustra*, &c. Subsequently he improved on this and recognized (1) an *Actinia* group, (2) a group like *Hydra* and *Sertularia*, and (3) *Polypes à Polypiers*, which he again divided into

<sup>1</sup> This fact is stated on the authority of the Rev. Mr Moulton, a missionary residing there, and it is the result of counting.

<sup>2</sup> From figures supplied by the Rev. W. W. Gill, B.A.

*Anthozoa* and *Bryozoa*. From 1830 onwards there was a distinct tendency to separate the *Polyzoa* from the polypes—they are spoken of as higher *Polypi*, compound polypes, &c. In 1831 Ehrenberg described the *Polypi* or *Curialia* as a class of the *Phytozoa*, and distinguished the true polypes or *Anthozoa* from the *Bryozoa*. Milne-Edwards expressly excludes the *Bryozoa*, and restricts the term polype to the *Zoantharia* and *Alcyonaria* inclusive of *Hydra* and *Lucernaria*. In 1847 Frey and Leuckart placed the *Polyzoa* by themselves, and united the remaining *Polypi* of Cuvier along with the *Acalephæ* under the class name *Cœlenterata*, which the latter afterwards (1853) divided into (1) *Ctenophora*, (2) *Medusæ*, and (3) *Polypes*. Modern anatomists generally agree in confining the term to the individuals (*zooids* or *personæ*) of hydriform *Hydromedusæ* and *Actinozoa*, and frequently restrict it to the former (see *HYDROZOA*, *CORALS*).

**POLYPTERUS**, a genus of Ganoid fishes common in many rivers of tropical Africa, and known on the Nile by the name of *abū bishīr*. Their body is cylindrical in shape, elongate, and covered with hard, polished, ganoid scales, which are arranged in oblique series. The head, with flattened snout and wide mouth, is protected by bony plates with ganoid external surface, of which a series of "supra-temporal" and "spiracular" ossicles are especially characteristic. Spiracles, or external openings of a canal leading into the pharynx are persistent throughout life, situated on each side of the parietal bone, and closed by an osseous valve. The lips are fleshy, but the space between the rami of the mandible is covered by a large "gular" plate. The vent is placed far backwards, in front of the anal fin, the tail being short, with a diphycercal termination of the vertebral column. The mouth is well provided with rasp-like teeth, forming broad bands in the jaws, on the vomer and palatine bones. The paired fins are supported by an axial skeleton. The structure of the dorsal fin is unique: its anterior portion is composed of isolated finlets, from eight to eighteen in number, each of which consists of a flattened spine with a bifurcate termination; to the posterior aspect of the top of each spine several soft rays are attached, which result from the dichotomous division of a single ray, the basal portion of which is the spine. Posteriorly these finlets pass into the ordinary rays composing the caudal fin, which surrounds the tail. The ventral fins are well-developed, and inserted behind the middle of the length of the trunk. The respiratory apparatus consists of three and a half gills, and is protected by an osseous gill-cover.

An external gill of considerable size in the form of a tapering band fringed with respiratory laminae exists in young examples, and is attached to the end of the gill-cover. The air-bladder is double, and communicates with the ventral wall of the pharynx.

Such are some of the principal characteristics of one of the most interesting representatives of a type which in *Polypterus* has survived from the Devonian and Carboniferous formations to our period; for further details of its internal organization see *ICHTHYOLOGY*. The centre of distribution of *Polypterus* is the lake region of tropical Africa, from which the Nile and the great rivers of West Africa take their origin. A very remarkable fact is its total absence in the East-African river systems which belong to the Indian Ocean. Specimens of the bishir have been found in the Nile as low as Cairo, but it is very scarce throughout the middle and lower parts of that river; such individuals have evidently been carried by the current down from southern latitudes, and do not propagate the species in the northern parts. As mentioned above, the number of the rays which are modified into finlets varies considerably, and consequently several species have been distinguished by some naturalists, whilst others hold that there is one species of *Polypterus* only. The largest specimens observed had a length of 4 feet. Nothing is known of its habits and propagation, and observations thereon are very desirable. Some years ago an extremely interesting dwarf form of *Polypterus* was discovered in Old Calabar, and described under the name of *Calamoiichthys calabarius*. It much resembles the bishir but is smaller, and considerably more elongate.

**POLYPUS**, a term in surgery, signifying a tumour which is attached by a narrow neck to the walls of a cavity lined with mucous membrane. A polypus or polypoid tumour may belong to any variety of tumour, either simple or malignant. The most common variety is a polypus of the nose of simple character and easily removed. Polypi are also met with in the ear, larynx, uterus, vagina, and rectum. See *SURGERY*.

**POLYSPERCHON**, one of Alexander's generals, and the successor of Antipater as regent in Macedonia in 318 B.C. He was driven from the kingdom by Cassander in 316. For the leading incidents of his brief term of office see *PHOCION* (vol. xviii. p. 800); compare also *MACEONIA*.

**POLYXENA**, in Greek legend, a daughter of Priam, last king of Troy, and Hecuba. She had been betrothed to Achilles, and after his death and the destruction of Troy the ghost of Achilles appeared to the returning Greeks as they were encamped on the Thracian Chersonese and demanded of them the sacrifice of Polyxena. The Greeks consented and Neoptolemus, son of Achilles, sacrificed Polyxena on his father's grave. This tragic story is the subject of the *Hecuba* of Euripides and the *Troades* of Seneca. Of Sophocles's tragedy *Polyxena* a few fragments only remain.

## P O L Y Z O A

**POLYZOA** is the name applied by J. Vaughan Thompson in 1830 (1)<sup>1</sup> to a group of minute polyp-like organisms which were subsequently (1834) termed "*Bryozoa*" by Ehrenberg (2). The forms included in this group were stated by Thompson to be "in a general way the whole of the *Flustraceæ*, in many of which I have clearly ascertained the animals to be *Polyzoæ*," they having been previously considered by zoologists to be allied to the *Hydra*-like polyps. These organisms had previously been known by the hard corneous "cells" or chambers which are formed by the animals on the surface of their bodies, and build up, in consequence of the formation of dense colonies by budding, complex aggregates known as "sea mats" and "sea mosses." Thompson expressly stated the opinion that the organization of the animals detected by him led to the conclusion that "they must be considered as a new type of the *Mollusca Acephala*."

Subsequently (1844) Henri Milne-Edwards (3) pointed out the relationship of Thompson's *Polyzoa* to the *Brachiopoda*, and, adopting the latter's view as to their *Molluscan* affinities, proposed to unite these two classes with the *Tunicata* in a group to be called "*Molluscoidea*." Recent researches have entirely separated the *Tunicata* from this association, and have demonstrated that they belong to the great phylum of *Vertebrata*. On the other hand the association of the *Polyzoa* with the *Brachiopoda* appears at present to be confirmed, though the relationship of these two classes to the *Mollusca* has been shown to rest on mistaken identification of parts; see, however, Harmer (18).

The *Polyzoa* appear to be related to the *Sipunculoid* *Gephyrean* worms (*Gephyræa inermia*) more nearly than to any other class of the animal kingdom. The study and interpretation of the facts of their ontogeny (growth from the egg) presents such extreme difficulty that in the present state of our knowledge it is necessary to regard them

<sup>1</sup> These numbers refer to the bibliography at the end of the article.

and interim as forming with the Brachiopoda and Sipunculoids an isolated group, to which the name "Podaxonia" may be applied, pending the decision of their affinities by the increase of our knowledge of the embryology of important members of the group.<sup>1</sup>

The forms included at the present day in Thompson's class of "Polyzoa" may then be thus classified:—

PHYLUM PODAXONIA.

CLASS I.—SIPUNCULOIDEA.

CLASS II.—BRACHIOPODA.

CLASS III.—POLYZOA.

Section 1.—VERMIFORMIA.

Sole genus: *Phoronis* (figs. 4 and 5).

Section 2.—PTEROBRANCHIA.

Genus 1: *Rhabdopleura* (fig. 7).

Genus 2: *Cephalodiscus* (figs. 8, 9, 10).

Section 3.—EUPOLYZOA.

Sub-class 1.—Ectoprocta.

Order 1.—PHYLACTOLÆMA.

Examples: *Lophopus*, *Plumatella* (fig. 2, B), *Cristatella* (fig. 3), *Fredericella*.

Order 2.—GYMNOLÆMA.

Sub-order 1.—Cyclostoma.

Examples: *Crisia* (fig. 13, A), *Hornera*, *Tubulipora*, *Discoporella*.

Sub-order 2.—Ctenostoma.

Examples: *Alcyonidium*, *Vesicularia*, *Serialaria*, *Bowerbankia* (fig. 1, A), *Paludicella* (fig. 1, E and fig. 2, A).

Sub-order 3.—Chilostoma.

Examples: *Cellularia*, *Scrupocellaria*, *Kinctoskias* (fig. 14), *Bugula*, *Bicellaria*, *Flustra* (fig. 1, G), *Mucronella* (fig. 1, C, D, F), *Membranipora*, *Lepralia*, *Eschara*, *Cellepora*, *Retepora*.

Sub-class 2.—Entoprocta.

Genera: *Pedicellina* (fig. 15), *Loxosoma* (fig. 16), *Urnatella*, *Ascopodaria*.

We shall most readily arrive at a conception of the essential structure of a Polyzoon, and of the variations to which that essential structure is subject within the class, by first examining one member of the group in detail and subsequently reviewing the characters presented by the divergent sub-classes, orders, &c., above indicated.

The most convenient form for our purpose is *Paludicella Ehrenbergii* (fig. 2, A), belonging to the typical section of the class (the Eupolyzoa) and to the order Gymnolæma. The organism occurs as minute tree-like growths (figs. 2, A and 1, E) attached to stones in freshwater streams and canals. The branches of the little tree are rarely more than an inch in length, and are regularly swollen and jointed at intervals. Each of the very numerous joints is about one-fifth of an inch long, and is in reality a tubular horny box attached above and below to the preceding and succeeding joints, and having on one side of it a spout-like aperture from which a crown of tentacles can be protruded. Each joint is thus inhabited by a distinct animal which is more or less completely shut off from the one in front of it and the one behind it, although it originated from the hinder and has given rise to the fore-lying individual by a process of budding, and retains a continuity of substance with both. A single cell or joint with its contained animal is represented in fig. 2, A.

*Paludicella* produces an arboriform colony, the main trunk or stolon being adherent to some stone or piece of wood. The substance of the wall of the cells is formed by a chemical body allied to chitin. Other Polyzoa may form mat-like expansions—the cells being placed in one plane, side by side (fig. 1, C, D, F, G), as well as in linear series; others again form solid masses, whilst many agree with *Paludicella* in the simple linear arrangement of their units. *Phoronis* and *Loxosoma*, on the other hand, do not form colonies at all—the former because it does not

bud, the latter because the buds become detached from their parent as soon as formed, as do the buds of the *Hydrozoon Hydra*.

On the whole *Paludicella* presents us with a very simple form of Polyzoon-colony (technically termed a "zoarium"), in which the aggregate of budded persons, each of which

is called a "polypide," does not exhibit any marked individuation, but is irregular and tree-like. But, just as in the Hydrozoa we find the Siphonophora presenting us with a very definite shape and individuality of the aggregate or colony, so in the Polyzoa we find instances of high indi-

<sup>1</sup> The research of Harmer (18) on *Loxosoma* is published too late for due notice in this article. It tends to the conclusion that the Eupolyzoa are after all degraded Mollusca, and have no connexion with the Vermiformia, Pterobranchia, Brachiopoda, and Sipunculoids. The reader is referred to Mr Harmer's memoir.

viduation of the zoarium of a similar kind. The most remarkable example is afforded by the locomotive zoarium or colony of *Cristatella* (fig. 3); and another very striking instance is that of the stalked zoaria of *Kinetoskias* (fig. 14) and *Adeona*.

The horny consistence of the cells which are produced by *Paludicella* is very usual in other Polyzoa; but we find frequently that the substance which forms the cells is gelatinous and soft instead of being horny, or again may be strongly calcareous. The term *coenacium* is applied to the mass of cells belonging to a colony or zoarium when considered apart from the living polypides which form it. Often such coenocia are found retaining form and structure when the soft living polypides have decomposed and disappeared. A single cell of the coenacium, corresponding to a single polypide, is called by the special students of the Polyzoa a *zoecium*.

If we examine a single cell or zoecium of *Paludicella* more carefully whilst its polypide is alive, we discover that the horny cell is nothing more than the cuticle of the polypide itself, to which it is absolutely adherent. At the so-called "mouth" or spout of the cell the cuticle suddenly changes its character and becomes a very delicate and soft pellicle instead of being thick and horny. There is no real discontinuity of the cuticle at this region, but merely a change in its qualities. This gives to that portion of the body of the polypide which lies beyond the spout a mobility and capacity for folding and pleating which is entirely denied to that part where the cuticle is more dense (fig. 2. A). Accordingly we find that the anterior portion of the body of the polypide can be pulled into the hinder part as the finger of a glove may be tucked into the hand. It is, in fact, an "introvert" (for the use of this term see *MOLLUSCA*, vol. xvi. p. 652). This arrangement is universal in the Ectoproctous Eupolyzoa, but does not obtain either in the Entoprocta, the Pterobranchia, or the Vermiformia. In Phoronis, Rhabdopleura, and Cephalodiscus the anterior part of the body can not be tucked or telescoped into the hinder part as it can in typical Eupolyzoa. On the other hand it is very important to note that the Sipunculoid Gephyreans are all pre-eminently characterized by possessing identically this arrangement. The introversion is effected in *Paludicella* (as in other Eupolyzoa) by a series of long detached retractor muscles of

considerable power (fig. 2, A, *mr*, *r'*, *m*); the same is true of Sipunculus.

The view has been advanced by Allman (4) that the retractile part of the polypide is to be considered as a distinct individual budded from the basal portion, which is regarded as an equivalent individual. It does not appear to the present writer that such a theoretical conception tends to facilitate the understanding of the structure and relations of these animals.

An "ectocyst" and "endocyst" have also been distinguished in former treatises, and these terms form part of a special "polyzoarial" nomenclature, but do not appear to be any longer needful. Equally undesirable is the misapplied term "endosarc" lately introduced by Jolliet (5) to denote a certain portion of the Polyzoon structure which will not be referred to here by that name.

The retractile or introversible portion of the body of the polypide of *Paludicella* is terminated by a crown of sixteen stiff non-contractile tentacles (fig. 2, A, *lr*) which form a circle around a central aperture—the animal's mouth. These tentacles are hollow and beset with vibratile cilia. The beating of the cilia causes a powerful current in the water by which food is brought to the animal's mouth. Each tentacle is also muscular, and can be bent and straightened at will. The tentacles not only serve to bring food into the mouth, but they are efficient as gill-filaments, being possibly homologous with (as well as functionally similar to) the gill-filaments of Lamellibranch Molluscs. They also serve as delicate tactile organs, and are the only sense organs possessed by the Eupolyzoa.

In *Paludicella* the platform around the mouth from which the tentacles arise, or *lophophore*, as it is termed, is circular. This is the case in all members of the large group of Gymnolæma and in the Entoprocta. But in the Phylactolæma the lophophore is drawn out on each side, right and left, so as to present a horse-shoe shape (fig. 2, B), and in some forms, notably *Lophopus* and *Acyonella*, the two arms or diverging rami of the horse-shoe are very strongly developed.

In the Pterobranchia the tentacles are confined in one genus (*Rhabdopleura*) to the two arm-like outgrowths of the lophophore, and are not simply hollow but contain a well-developed cartilaginous skeleton (fig. 7). In the allied genus *Cephalodiscus* there are not merely a single pair of such arm-like processes, each bearing two rows of tentacles, but the lophophore is developed into twelve arm-like processes (fig. 9), which form a dense tuft of filaments around the anterior extremity of the animal.

In the Vermiformia (Phoronis) we again meet with a very perfect horse-shoe-shaped lophophore (fig. 4). The tentacles upon the crescentic or otherwise lobed circumoral region of the Sipunculoids are the representatives of the tentacles of the Polyzoa; whilst the tentaculiferous "arms" of the Brachiopoda appear to be the equivalents of the Polyzoon's lophophore much drawn out and in most cases spirally rolled.

Just below the circular crown of tentacles in *Paludicella* we find an aperture which the study of internal anatomy proves to be the anus. In all Polyzoa the anus has this position near the mouth; and in this respect we again note an agreement with Sipunculus and the other so-called Gephyreæ inermia. In one division of the Polyzoa alone is there any noteworthy variation in the position of the anus, namely, in the Entoprocta (sub-class of the section Eupolyzoa). In these forms the anus, instead of lying just below the lophophore or platform from which the tentacles spring, is included like the mouth within its area (fig. 15, C).

Passing now to the deeper structure of *Paludicella*, we find that it is a Coelomate animal; that is to say, there

FIG. 2.—A. Polypide of *Paludicella Elasmbergii*, seen as a transparent object in optical section and highly magnified (from Gegenbaur, after Allman). For natural size see fig. 1. E. *a*, anus; *lr*, peristomial circle of ciliated tentacles; *f*, thickened cuticle of the body-wall, forming the horny cell or zoecium; *mr*, median retractor muscle of the introvertible part of the body; *r'*, anterior retractor of the same; *mr*, great retractor muscle of the same; *a*, ovary, passing from which to the stomach is the anterior mesentery or funiculus; *t*, testis; *o*, oesophagus; *s*, stomach; *p*, posterior mesentery or funiculus; *a'*, anterior mesentery or funiculus. Observe at the right upper corner of the figure the base of a second polypide and the "rosette-plate" of separation.  
B. Diagram of a polypide of *Paludicella*. Letters as above.

exists between the body-wall and the wall of the alimentary tract a distinct space termed "perigastric space," "body-cavity," or "coelom." This is true of all Polyzoa, though it has been erroneously stated by G. O. Sars that *Rhabdopleura* does not possess such a coelom. In Eupolyzoa (excepting the Entoprocta) the coelom is very capacious; it is occupied by a coagulable hæmolymp in which float cellular corpuscles, and also the generative products, detached, as is usual in Coelomata, from definite "gonads" developed on its lining membrane (fig. 2, A, o, t). This lining membrane or "coelomic epithelium" is ciliated in the *Phylactolæma*, but its characters appear not to have been definitely determined in other Eupolyzoa. The coelomic space and the tissues bounding it are continuous throughout the colony or zoarium of a Polyzoon—either directly without any constriction marking off one polypide from another, or through perforate septum-like structures as in *Paludicella* (see right-hand upper process of fig. 2, A), which form incomplete barriers between juxtaposed zoecia, and are termed "rosette-plates" or "communication-plates." The coelomic cavity is continued in *Paludicella* and probably in all Polyzoa into the tentacles, so that these organs expose the hæmolymp fluid to a respiratory action, and hence may be called branchial.

The body-wall of *Paludicella* consists, alike in the anterior introversible region and in the posterior region, of an outer cuticle which has already been spoken of as thickened around the base of the polypide so as to become there the hard tube-like zoecium. Beneath this is the delicate layer of living epidermic cells which are the mother-cells or matrix of that cuticle. Beneath this again are a few scattered annuli of muscular fibre-cells arranged ring-wise around the cylindrical body; more deeply placed than these are five large bundles of longitudinally placed muscular fibre-cells which are attached at three different levels to the soft introversible portion of the body, and by their retraction pull it in three folds or telescopic joints into the capacious hinder part of the body. In some Polyzoa the muscular fibre-cells present transverse striations. These folds are shown in fig. 2, A;

FIG. 2.—The locomotive zoarium of the freshwater *Phylactolamous Polyzoon Cristatella mucosa*; magnified six times linear (after Allman). a, individual polypides with their horse-shoe-shaped crown of tentacles exerted; b, statoblasts seen through the transparent tissues; c, the muscular foot or base of the colony by means of which it crawls; d, portion of water-weed upon which the *Cristatella* is crawling.

but when the longitudinal muscles are completely contracted the tentacular crown would be pulled down far out of sight into the midst of the body by the great longitudinal muscle *mr*. Deeper than the longitudinal muscles, and clothing them and everything else which projects into the coelom, is the coelomic epithelium, not easily observed, and sufficiently known only in the *Phylactolæma*. Part of it gives rise to the generative products (fig. 2 A, o, t). Other Eupolyzoa have a similar but not identical arrangement of the longitudinal muscles—acting essentially as retractors of the "introvert" or soft anterior region of the body—and a similar structure of the body-wall which is in

essential features identical with that of the Sipunculoid worms, the Chaetopod worms, and other typical Coelomate animals.

The alimentary canal of *Paludicella* forms a closely compressed U-shaped loop depending from the closely approximated mouth and anus into the capacious coelom. It is clothed on its coelomic surface (in *Phylactolæma* at any rate) with coelomic epithelium, and beneath this are extremely delicate muscular layers. Within it is lined, except in the immediate region of the mouth (which is lined by the in-pushed outer cell-layer), by the enteric cell-layer—the digestive cells derived from the archenteron of the embryo. We can distinguish in *Paludicella* a contractile pharyngo-oesophagus (fig. 2, A,  $\alpha$ ), a digestive stomach  $\gamma$  (the lining cells of which have a yellow colour), and an intestine which forms that arm of the loop connected with the anus. This simple form of alimentary canal is uniformly present in Polyzoa. In *Roverbankia* and its allies a muscular gizzard with horny teeth is interposed between oesophagus and digestive stomach.

The alimentary canal of *Paludicella* does not hang quite freely in the coelomic cavity, but, as is usually the case in other classes where the coelom is large, mesenteries are present in the form of fibrous (muscular?) bands clothed with coelomic epithelium and suspending the gut to the body-wall. In *Paludicella* there are two of these mesenteries, an anterior ( $\alpha'$ ) and a posterior ( $\alpha$ ). The presence of two mesenteric bands is exceptional. Usually in the Eupolyzoa we find one such mesentery only, corresponding to the hinder of the two in *Paludicella*. The special name *funiculus* (Huxley) is applied to this mesenteric band, and it is noteworthy that the cells of the coelomic epithelium, either upon its surface or at its point of insertion into the body-wall, are modified as reproductive elements, forming either the testis or ovary; in the *Phylactolæma* they form here also special asexual reproductive bodies, the statoblasts. The nervous tissue and organs of *Paludicella* have not been specially investigated, but in many Eupolyzoa an oval mass of nerve-ganglion cells is found lying between the mouth and anus, and there is no doubt that it is present in this case. In *Plumatella* nerve-fibres have been traced from this ganglion to the tentacles and other parts around the mouth (fig. 11,  $w$ ,  $x$ ,  $y$ ). A "colonial nervous system" was described some years ago by Fr. Müller in *Serialaria*; but modern histologists do not admit that the tissue so named by Müller is nerve-tissue. The ganglion above mentioned is the only nervous tissue at present known in Polyzoa (but see fig. 17,  $x$ ).

No heart or blood-vessels of any kind exist in *Paludicella* nor in any of the Eupolyzoa or Pterobranchia. On the other hand the isolated vermiform genus *Phoronis* presents a closed contractile system of longitudinal vessels (dorsal and ventral) which contain nucleated corpuscles coloured red by hæmoglobin (figs. 4, 5).

No excretory organs (nephridia) or genital ducts have been observed in *Paludicella*, nor have such organs been detected in the majority of the Polyzoa which have been studied. In the Entoprocta, however, a pair of minute ciliated canals are found in the nearly obliterated body-cavity opening to the exterior near the tentacular crown in both *Pediecellina* and *Loxosoma*, which represent the cephalic nephridia of worms. A definite pair of nephridia occur in *Phoronis*. A similar significance is perhaps to be attributed to the "intertentacular organ" of Farre—a ciliated passage opening between two tentacles of the lophophore in *Membranipora*, *Alcyonidium*, and other forms—through which Hincks has observed the spermatozoa to escape in large numbers. This organ occurs equally in female specimens of *Membranipora*, and is not therefore simply a spermatid duct.

Paludicella, as we have seen, develops both ova and spermatozoa in one and the same polypide. The details of impregnation and development have not been followed in this instance, but in some of the marine Eupolyzoa (*Gymnolama*) remarkable bud-like structures termed *ovaria* are developed for the special reception of the ova, and in these organs fertilization takes place. In the Entoprocta there is a peculiar brood-pouch. The spermatozoa of one polypide probably in all cases fertilize the ova of another, but we have not yet in many cases a knowledge of how the spermatozoa get to the eggs, or how the eggs escape from the body-cavity of the parent. In the hippocrepian freshwater Polyzoa (*Phylactolama*) the ova appear to be fertilized and undergo the early stages of development within the body-cavity of the parent or in a hernia-like protrusion of it. Probably in such cases the embryos escape by the death of the parent and rupture of the parental tissues, as do also the peculiar asexual internal buds or strobilists of these forms.

The embryo Polyzoon or "larva" swims freely in its early condition by means of cilia, and is in this condition a single polypide or "person." The forms assumed by these ciliated larvae in different Polyzoa are very various and exceedingly difficult of interpretation. We shall have more to say with regard to them below (see figs. 19, 20, 21). The ciliated larva then fixes itself and commences to produce polypides by a process of budding the buds remaining not merely in contact but in organic continuity, and increasing continually in number so as to form a large colony or zoarium. In *Paludicella* we have seen that this colony has a simple tree-like form. The new buds form as wart-like growths, usually one, sometimes two in number, at the free end of a cell or zoarium near the strobil-like process from which the tentacular crown is erected. In *Paludicella* all the polypides of a colony are alike; there is no differentiation of form or distribution of function amongst the members of the colony. In many Eupolyzoa this simplicity is by no means maintained, but a great variety of form and function is assumed by various members of the aggregate. The only approach to a differentiation of the polypides in *Paludicella* is in the arrest of growth of some of the buds of a colony in autumn, which, instead of advancing to maturity, become conical and invested with a dark-coloured cuticle. They are termed *hibernacula*. Should the rest of the polypides die down in winter, these arrested buds survive and go on to complete development on the return of spring.

In *Paludicella* we have thus seen a fairly simple and central example of Polyzoon structure and life-history. The variations upon this theme presented in different groups of Polyzoa have been to some small extent noted in the preceding account, but we shall now be able to indicate them more precisely by considering the various groups of Polyzoa in succession. The limit assigned to this article necessitates very large omissions. The reader who wishes to have the fullest information on the many difficult and uncertain matters connected with this subject is referred to Allman, *Freshwater Polyzoa* (Ray Society, 1856); Hincks, *British Marine Polyzoa* (Van Nostrand, 1889); Haddon, "Budding in Polyzoa," *Quart. Journ. Micro. Sci.* 1883; Balfour, *Embryology*, vol. i. p. 242; and the original memoirs cited by these writers.

#### THE VERMIFORMIA.

The first section of the Polyzoa comprises but a single genus, *Phoronis*. It differs from all other Polyzoa first in its greater size (species 2 inches long are known) and elaboration of organization, and correlatively with that in the fact that it does not produce buds. Further,

it does not produce a closely adherent cuticular zoecium as do *Paludicella* and the Eupolyzoa generally, but a leathery tube in which the animal freely moves, resembling that of some Chaetopods (*Sabella*). Like some *Sabella*, *Phoronis* forms closely packed aggregates of individuals not brought together by any process of budding, but each separately developed from an egg. *Phoronis* has an elongate, worm-like, unsegmented body, with a conical posterior termination (like *Sipunculus*), and anteriorly provided with a horse-shoe-shaped crown of tentacles surrounding the mouth (figs. 4, 5). There is an inter-tentacular "web" between the bases of the tentacles as in the *Phylactolama*. Caldwell (6) has recently shown that the tentacles are supported by a mesoblastic skeleton, as is also the case in *Rhabdopleura*, but apparently not the case in any other Polyzoa. Close to the mouth as in all Polyzoa is placed the anus, outside the horse-shoe-shaped

FIG. 4.—*Phoronis hippocrepia*, Walcott; magnified six times from life. *a*, horseshoe-shaped tentacles with tentacles; *b*, epistome (protruding from the mouth); *c*, epistome (protruding from the mouth); *d*, epistome (protruding from the mouth); *e*, epistome (protruding from the mouth); *f*, epistome (protruding from the mouth); *g*, epistome (protruding from the mouth); *h*, epistome (protruding from the mouth); *i*, epistome (protruding from the mouth).

lophophore or tentacular platform (fig. 11. i). The tentacular crown is not introvertible; in this point *Phoronis* differs from *Paludicella* and the Entoproctous Eupolyzoa, and agrees with the Entoprocta and the Pterobranchia. Overhanging the mouth is a small pre-oral lobe or "epistome" (figs. 4, 5. c). This organ is aborted in *Paludicella*, and indeed in all the *Gymnolama*, but is present in the other Polyzoa, and is especially large and well developed in *Rhabdopleura* and *Cephalodiscus*. It has been compared to the Molluscan foot but undoubtedly in *Phoronis* it is the persistent representative of the pre-oral

FIG. 5.—Anterior view of the anterior end of *Phoronis*. The epistome of the mouth of the tentacles are shown in relation to the epistome of the mouth and the epistome of the mouth. *a*, epistome (protruding from the mouth); *b*, epistome (protruding from the mouth); *c*, epistome (protruding from the mouth); *d*, epistome (protruding from the mouth); *e*, epistome (protruding from the mouth); *f*, epistome (protruding from the mouth); *g*, epistome (protruding from the mouth); *h*, epistome (protruding from the mouth); *i*, epistome (protruding from the mouth).

been compared to the Molluscan foot but undoubtedly in *Phoronis* it is the persistent representative of the pre-oral

lobe of the larva (fig. 6), and therefore cannot be compared to the Molluscan foot. If we are right in associating Phoronis with the Polyzoa, this fact is sufficient to show that the epistome of the Phylactolema (fig. 11, c) and the buccal shield of Rhabdopleura (fig. 7, d) and of Cephalodiscus (fig. 9, b) are also cephalic in nature, and cannot rightly be identified with the post-oral and ventral muscular lobe known as the foot in Mollusca. A circum-oral nerve ring occurs at the base of the tentacles and sends off a cord which runs along the left side of the body. The alimentary canal presents the same general form and regions as in Paludicella. It hangs in the body-cavity, to the walls of which it is suspended by definite mesenteries.

Phoronis presents a closed contractile vascular system containing red-coloured blood-corpuscles (figs. 4, 5, f, g, h). A pair of ciliated canals acting as genital pores is found near the anus; these have been shown by Caldwell to be typical nephridia.

The development of Phoronis is remarkable. The egg gives rise (after the usual phases of cleavage and gastrulation) to the larval form known as *Actinotrocha* (fig. 6). This larva possesses a hood-like region overhanging

præ-oral hood. The præ-oral hood becomes the epistome, and the tentacles, by further development (new tentacles replacing the larval ones), become the horse-shoe-shaped group of tentacles of the adult. A very curious process of growth changes the long axis of the body and results in the anus assuming its permanent position near the mouth. An invagination appears on the ventral face of the larva between the anus and mouth, and attains considerable size. At a definite moment in the course of growth this invagination is suddenly everted, carrying with it in its cavity the intestine in the form of a loop. Thus a new long axis is suddenly established at right angles to the original oro-anal axis, and continues to develop as the main portion of the body. The short area extending from the præ-oral hood to the anus is thus the true dorsal surface of Phoronis, whilst the elongated body is an outgrowth of the ventral surface perpendicular to the primary oro-anal axis, as conversely in many Mollusca we find a short ventral area (the foot) between mouth and anus, and an outgrowth of the dorsal surface (the visceral hump) perpendicular to the primary oro-anal axis, forming the chief body of the animal. In these relations Phoronis (and with it the other Polyzoa) agrees with Sipunculus. On the other hand Echiurus, the Chaetopods, Nemertine worms, and some other groups which start from a simple larval form not unlike that of Phoronis, present a continual elongation of the original oro-anal axis, and no transference of the long axis by the perpendicular or angular growth of either the ventral or the dorsal surface of the larva.

Phoronis was discovered originally in the Firth of Forth by Dr Strethill Wright. It occurs in the Mediterranean and in Australian seas (Port Jackson).

#### THE PTEROBRANCHIA.

This section of the Polyzoa also comprises forms which differ very widely from Paludicella. Inasmuch as their development from the egg is at present quite unknown, it may possibly prove that they have other affinities. Only two genera are known, Rhabdopleura (Allman) and Cephalodiscus (M'Intosh), the former dredged by Dr Norman in deep water off the Shetlands (and subsequently in Norway), the latter taken by the "Challenger" expedition in 250 fathoms off the coast of Patagonia.

The Pterobranchia have the mouth and anus closely approximated, and immediately below the mouth are given off a series of ciliated tentacles, but these do not form a complete circle as in Paludicella, nor is the lophophore (the platform of their origin) horse-shoe-shaped as in Phoronis. The lophophore is drawn out into a right and a left arm in Rhabdopleura (fig. 7), upon each of which are two rows of ciliated tentacles; no tentacles are developed centrally in the region between the two arms, so that the mouth is not completely surrounded by these processes. The horse-shoe-shaped lophophore of Phoronis could be modified so as to represent the tentaculiferous arms of Rhabdopleura by suppressing both rows of tentacles at the curve of the horse-shoe, and leaving only those which occur on the arms or rami of the horse shoe (see fig. 4). The lophophore of Cephalodiscus presents us with twelve processes, each carrying two rows of ciliated tentacles; in fact we have six pairs of tentaculiferous arms instead of a single pair, and each of these arms is precisely similar to one of the arms of Rhabdopleura (fig. 9), excepting that it terminates in a knob instead of tapering. There is no arrangement for introverting the anterior portion of the body into the hinder portion in the Pterobranchia.

The little epistome or præ-oral lobe of Phoronis is represented in the Pterobranchia by a large muscular shield or disk-like structure (fig. 7, d and fig. 9, b) which overhangs the mouth and has an actively secreting glandular

FIG. 6.—Development of Phoronis and typical ciliate larva. a number of ciliated post-oral processes is placed at the extremity of the opposite to that bearing the mouth and

surface by which the tube or case (tubarium) in which the polypide is enclosed is secreted.

Both *Rhabdopleura* and *Cephalodiscus* produce colonies by budding; but the colonies of the former are large, definite, and arborescent, whilst those of *Cephalodiscus* are remarkable for the fact that the buds do not remain long in organic continuity with their parent, but become detached and nevertheless continue to be enclosed by the same common envelope or secretion. The bud-formation of *Rhabdopleura* recalls that of *Paludicella* in the fact that it leads to the formation of continuous arboriform communities. That of *Cephalodiscus* resembles the budding of *Loxosoma*, since no two fully-formed individuals remain

FIG. 7.—*Rhabdopleura Normani*. ALLMAN (original drawings, Lankester). A. Part of a lophophore-arm. a, ciliated patch (Sars's organ) at the base of the lophophore-arm. Other letters as above. E. Part of a lophophore-arm with soft tissues rubbed off to show the cartilaginous skeleton. a, epithelium and soft tissues still adherent at the tip of a tentacle; b, skeleton of tentacle; c, skeleton of axis. F. Portion of a colony of *Rhabdopleura Normani*, showing the branched tube-like cases formed by the polypides. The black line within the tubes represents the retracted polypides connected together by their common stalk, the pectoculus. Magnified to three times the size of nature.

in organic continuity. Both *Rhabdopleura* and *Cephalodiscus* (like *Phoronis*) produce cases or investments in which they dwell. These are free secretions of the organism, and are not, like the cenocia of *Eupolyzoa*, cuticular structures adherent to and part of the polypide's integument. The dwelling of *Rhabdopleura* is a branched system of annulated tubes of a delicate membranous consistency, each tube corresponding to a single polypide, the rings of which it is built being successively produced at the termination of the tube by the secreting activity of the præ-oral disk (fig. 7, E). The polypides freely ascend and descend in these tubes owing to the contractility of their stalks. On the other hand the dwelling of *Cephalodiscus*

is a gelatinous, irregularly branched, and fimbriated mass (fig. 8), excavated by numerous cavities which communicate with the exterior. In these cavities are found the numerous detached small colonies of *Cephalodiscus* (fig. 9), or we should rather say the isolated budding polypides. The remaining important feature in the organization of the *Pterobranchia*, namely, the parts connected with the formation of buds, are best understood by first examining *Cephalodiscus*. The body of *Cephalodiscus* is seen (fig. 9) to be an oval sac; in this is suspended the U-shaped alimentary canal, and from the walls of its cavity (coelom) the ova and the spermatozoa are developed. Projecting from the ventral face of this oval sac is a muscular cylindrical stalk, into which the viscera do not pass, though the coelom is continued into it (fig. 9, c). This stalk is merely the outdrawn termination of the body. It is about as long as the whole of the rest of the animal, and it is from its extremity that the buds are produced (fig. 9, a). Before the buds have attained half the size of their parent they become detached, but continue to occupy some portion of the common gelatinous dwelling.

FIG. 8.—Dwelling of gelatinous consistence and brown colour formed by the polypides of *Cephalodiscus dodecatophus*, McIntosh; natural size (from an original drawing kindly supplied by Prof. McIntosh, F.R.S.). a, polypide within the jelly; p, cavity once occupied by polypides.

FIG. 9.—A polypide of *Cephalodiscus dodecatophus* removed from the gelatinous house (from an original drawing by Prof. McIntosh). No organic connexion has been severed in thus isolating this polypide with its attached buds a, a. The figure represents the furthest point to which colony-formation attains in this form. a, buds growing from the base of the polypide-stalk; b, the præ-oral lobe (buccal shield or disk); c, the polypide-stalk; d, the ciliated tentacles of the twelve lophophore arms (six pairs, each like the single pair of *Rhabdopleura*) inextricably matted and confused; e, anterior margin of the præ-oral lobe; f, posterior margin of the same. Magnified about fifty times linear.

Turning to *Rhabdopleura*, we find that each polypide has a body of similar shape and character to that described for *Cephalodiscus*, and a similar ventrally developed "stalk" (fig. 7, A, c). But, inasmuch as the buds deve-

loped on the stalk of a *Rhabdopleura* polypide do not detach themselves, we find that we can trace the stalk of each polypide of a colony into connexion with the stalk of the polypide from which it was originally budded, which may now be considered as a "branch" bearing many-stalked polypides upon its greatly extended length, and such a "branch-stalk" may be further traced to its junction with the "stem-stalk" of the whole colony. The stem-stalk was at one time the simple terminal stalk of a single polypide, but by lateral budding it gave rise to other polypides, and so became a gemmiferous "branch"; and further, when some of these in their turn budded and became branches, it became the main "stem" of a copious colony.

A serious error has been made in comparing the contractile stalk of the Pterobranchiate polypide to the "funiculus" or cord-like mesentery of Eupolyzoa. With this it has morphologically nothing in common, since it is not an internal organ, but simply the elongated termination or stalk of the body, comparable to the stalk of *Pediacellina* (fig. 15) and *Loxosoma* (fig. 16), or to the hydrocaulus of such a Hydrozoon colony as *Cordylophora*. The stalk where it bears only very young buds, or none at all, as is always its condition in *Cephalodiscus* and in many polypides of a *Rhabdopleura* colony, may be called a "gymnocaulus"; when once its buds have developed into full grown polypides, and it has elongated proportionally with their growth, it becomes a "pectocaulus"; that is to say, it is to that part of it which bears such polypides that this term may be conveniently applied. The pectocaulus of *Rhabdopleura*, both in the form of branch and stem, undergoes remarkable change of appearance as compared with the gymnocaulus. It loses its contractility, shrinks, and develops on its surface a hard, dark, horny cuticle (whence its name), comparable precisely in its nature to the hardened cuticle which forms the zoecia of Eupolyzoa. It now has the appearance of a black cord or rod-like body lying within and adherent to the inner face of the much wider tubular stem, and branches formed by the gradual building up and arborescent extension of the annulated tubarium secreted by the individual polypides. It has been regarded both by Allman and by Sars as a special structure, and called by the former "the chitinous rod" or "blastophore," by the latter "the axial cord."

In reality it is the black-coloured pectocaulus of *Rhabdopleura* which corresponds to the coenecium of an ordinary Polyzoon; whilst the term "coenecium" is totally inapplicable morphologically to the annulated branched tube in which the *Rhabdopleura* colony lives, this having absolutely no parallel in the Eupolyzoa.

A sac-like testis has been discovered in *Rhabdopleura* opening by the side of the anus (Lankester, 7); but the ova have not yet been seen, nor is anything known of its development. Similarly the eggs of *Cephalodiscus* are observed within the body of the parent in the "Challenger" specimens, but nothing further is known of its life-history.

A body-cavity is present (Lankester), though its existence has been denied by Sars and by McIntosh. Nephridia and nerve ganglia are not described. *Cephalodiscus*

has two remarkable eye spots dorsal to the cephalic disk (fig. 10, g).

### THE EUPOLYZOA.

Whilst it is necessary to include in the group Polyzoa the forms we have already noticed as Vermiformia and Pterobranchia, there can be no doubt that those organisms to which we assign the name Eupolyzoa are primarily those upon which naturalists have framed their conception of the group, and that they constitute a very consistent assemblage, held together by well-defined characters, and yet presenting an immense number of varied forms showing a wide range of modifications.

All the Eupolyzoa have closely approximated mouth and anus, and, like *Paludicella*, a complete range of hollow ciliate tentacles, describing either a circle or a horse shoe, surrounding the mouth. The anus as well as the mouth is included in this area in a few exceptional forms (the Entoprocta); it lies near but outside the lophophore (as the area is termed) in the vast majority (the Ectoprocta). Except in the Entoprocta, where the movement is limited, the whole anterior portion of the body bearing the lophophore can be invaginated into the hinder part (as described above for the typical Eupolyzoon *Paludicella*). This character distinguishes the Eupolyzoa from both Vermiformia and Pterobranchia. The polypides of all the Eupolyzoa are minute, but all produce buds which remain in organic continuity with their parent (except in *Loxosoma*) and build up very considerable and sometimes massive colonies.

In all Eupolyzoa the cuticle of the hinder part of each polypide is thick and dense, thus forming a hard-walled sac, the zoecium. This is peculiar to and universal in the Eupolyzoa (except *Loxosoma*), and is not to be confounded with the non-adherent tubes of *Phoronis* and *Rhabdopleura* or the jelly-house of *Cephalodiscus*. The connected zoecia of a colony of Eupolyzoa constitute a coenecium. A simple nerve ganglion between mouth and anus, a large body-cavity (except in Entoprocta), simple gonads without accessory glands or ducts, usually testis and ovary in the same polypide, absence of a blood-vascular system, of any but the most rudimentary nephridia, and of eyes, otocysts, or other special sense-organs, are features characterizing all adult Eupolyzoa.

The section Eupolyzoa, with its vast number of species and genera, requires a somewhat elaborate classification. The forms in which the anus is enclosed within the tentacular circle are very few, and are peculiar in other respects. We follow Nitsche (8) in separating them as the sub-class Entoprocta from the majority of Eupolyzoa forming the sub-class Ectoprocta.

#### Sub-class 1. Ectoprocta, Nitsche.

Eupolyzoa with the anus not included within the area of the lophophore. Anterior portion of the body of the normal polypide introversible. Tentacles not individually capable of being coiled or flexed.

#### Order 1. PHYLACTOLEMA, Allman.

Ectoproctous Eupolyzoa in which the polypide possesses a præ-oral lobe or epistome, similar to that of *Phoronis*, and comparable to the more highly developed buccal shield or disk of the Pterobranchia. Lophophore (except in *Fredericella*, where it is nearly circular) horse-shoe-shaped (hippocrepian). Polypides of a colony equi-formal, that is, not differentiated in structure and function. Neighbouring zoecia are in free and open communication, the bud never becoming shut off by a perforated cuticular plate from its parent. Cuticle of the zoecia either gelatinous or horny, forming massive or else arborescent coenecia, in one genus

FIG. 10.—A polypide of *Cephalodiscus doerbalphus*, from which the lophophore-tentacles and buccal shield have been removed in order to show the remarkable eyes. *a*, buds; *c*, stalk; *g*, eyes; *h*, post-oral collar, hidden by the buccal shield in fig. 9. (Original drawing by Prof. McIntosh F.R.S.)

(Cristatella) having the form of a plano-convex ellipse and locomotive (fig. 3). In addition to the multiplication of polypides in a colony by budding, and to the annual production of new individuals from fertilized eggs which initiate new colonies, a reproduction by internal buds called "statoblasts," comparable to the gemmæ of Spongia, has been observed in all the genera (fig. 3, b). The statoblasts are developed from the funiculus (mesentery), and are enclosed in ornate lenticular capsules of chitinous substance, characteristic in form in each species.

The fertilized egg of the Phylactolæma does not give rise to a zonociliate larva, but to a uniformly ciliate cyst-like diblastula, which develops directly and produces polypides by budding. The Phylactolæma are all inhabitants of fresh water (lacustrine).

FIG. 11.—Semi-ideal view of part of the lophophore of *Lophopus* and its tentacles, —intended to show the nerve-ganglion, nerves, and parts around the mouth. The tentacles have been cut away all along the right arm of the lophophore and from the inner margin of the left arm. *a*, foramen placing the cavity of the epistome in communication with the body-cavity; *b*, body-wall; *c*, mouth; *d*, the epistome or præ-oral lobe; *e*, wall of the pharynx; *f*, wall of the pharynx; *g*, wall of the intestine; *h*, anus; *i*, lophophore; *j*, a ciliated tentacle; *k*, elevator muscle of the epistome; *l*, the nerve-ganglion; *m*, *n*, nerves to lophophore and tentacles; *y*, nerve to pharynx.

The Phylactolæma include the genera *Lophopus*, *Cristatella*, *Alcyonella*, *Plumatella*, and *Fredericella*, which have been beautifully figured and described in Allman's classical *Freshwater Polyzoa*, Ray Society, 1836. The colonies of *Lophopus* are small, consisting of half a dozen polypides embedded in a massive glass-like cœnocœcium. *Cristatella* (fig. 3) is remarkable amongst all Polyzoa for its locomotive zoarium. *Alcyonella* forms massive cœnocœcia of many hundred polypides, as large as a man's fist. *Plumatella* and *Fredericella* are delicate arborescent forms commonly encrusting stones and the leaves of water-plants. All the genera known are British.

The Phylactolæma furnish a remarkable instance of a well-marked zoological group being confined to fresh water. Their reproduction by statoblasts (not known in the marine Polyzoa) appears to be related to the special conditions of lacustrine life, since it is also observed under the same exceptional conditions in the single freshwater genus of another great group of animals, viz., Spongia. Also related to their non-marine conditions of life is the development of the fertilized egg, which, as in so many similar cases, does not produce the remarkable banded forms of locomotive larvæ which are characteristic of their marine congeners.

## Order 2. GYMNOLEMA, Allman.

Ectoproctous Eupolyzoa in which the polypide is devoid of any trace of the præ-oral lobe or epistome, whilst the

lophophore is perfectly circular. The polypides of a colony are frequently highly differentiated as avicularia, vibracularia, oœcia (egg-receptacles), and even as root and stem segments. The neighbouring polypides of a colony communicate (?) with one another by "rosette-plates" or "communication-plates"—perforated areas in the walls of contiguous zoœcia. The greatest variety in the character of the cuticle forming the zoœcia (gelatinous, horny, calcareous) and in the grouping of the polypides, as well as in the shape of their zoœcia, is observed in different sub-orders and families. In addition to the ordinary sexual reproduction, there are various modifications of the process of budding, the full exposition of which would necessitate more space than is here allotted, and is not yet indeed within the possibilities of present knowledge. The fertilized egg of the Gymnolæma gives rise to remarkable ciliate larvæ of various forms (figs. 19, 20, 21), from which the first polypide of a colony is developed by an extraordinary and unexplained series of changes. The Gymnolæma are, with the single exception of the genus *Paludicella*, inhabitants of the sea.

The Gymnolæma are divided, according to the system of Busk, into three sub-orders, characterized by the shape of their zoœcia, and the nature of the mouth-like margin which it presents when the exsertile portion of the polypide is withdrawn within it. The Cyclostoma have long tubular zoœcia, often of large size and often calcified, placed side by side in cylindrical bundles, or in other definite grouping; the mouth of the zoœcium is circular and devoid of processes. There is little or no differentiation of the polypides constituting a colony. Most of this group are fossil, and the living genera belong mostly to southern seas. The genera *Crisia* (fig. 13, A), *Diastopora*, *Tubulipora*, and *Hornera* are typical. The Ctenostoma have usually a soft zoœcium; its orifice is closed by the folds of the retracted polypide or by a circlet of bristles which surround it. *Alcyonidium gelatinosum* is the commonest representative of this group on the British coasts. *Bowerbankia* (fig. 1, A) and *Paludicella* (fig. 1, E) also belong here. The Chilostoma form the largest and most varied sub-order of Gymnolæma. The zoœcia are

FIG. 12.—Two zoœcia of *Acamarchis* (*Bugula*) *aricularia*, Lmx. (*Chilostoma*), of which the anterior contains a living polypide, whilst the posterior is empty. To each is attached one of the characteristically modified polypides known as an "avicularium" *a*; the hinder of these has grasped and holds in its beak a small worm. *b*, anus; *c*, intestine; *d*, stomach; *e*, body-cavity (cœlom); *f*, lenticular crown surrounding the mouth; *g*, tentacles developed on the surface of the terminal mesentery or "funiculus"; *h*, avicularia.

are horny or calcified; their orifices can be closed by a projecting lip in the form of an operculum. The operculum is a separable plate developed on the cuticle of the retractile part of the polypide, and has muscles attached to it (fig. 13, B, C, D). The surface of the zoœcia is frequently sculptured, and its orifice provided with processes and spines (fig. 1, C, F). Very usually some of the polypides of a colony are modified as avicularia, vibracularia, radical fibres, and oœcia. The avicularium is a polypide reduced to a simple muscular apparatus working upon the modified operculum and zoœcium so as to cause these hard parts to act as a snapping apparatus comparable to a bird's head (fig. 12, o). They are frequently found regularly distributed among the normal cells of a colony, and probably have a cleansing function similar to that attributed to the Pedicellariæ of the Echinoderms. "Vibracularia" are even more simplified polypides, being little more than motile filaments, probably tactile in function. The opercula of rosetta, oœcia, and avicularia have recently been used by Busk in characterizing genera and species, in a systematic way. Stem-building and root-forming polypides are frequently found, being closed polypides which subserve anchoring or supporting functions for the benefit of the whole colony. The stem of *Kinetoskias* (fig. 14) is produced

in this way. The Chilostoma include a large series of genera arranged in the sections Cellularina, Flustrina, Escharina, and

FIG. 13.—A. Cannelum of *Crisia eborea*, Linn., one of the Cyclostoma; g, g, tubular zoecia with circular terminal mouths; x, oecium, being a zoecium modified to serve as a brood-chamber.  
B. C. The same zoecium with the polypide invaginated (telescoped) and the operculum a shut down over the mouth of the zoecium.  
D. Operculum detached, and seen from its inner face, to show the occlusor muscles d d.

Celleporina. For the systematic description of the highly complex and very varied colonial skeletons or cannelia of the Gymnolæma,

FIG. 14.—*Kittiwella (Nereida) gracilis* (from Dr. Wyville Thomson). The polypides of this genus are allied to *Siphonia*, but the zoecium as a whole is remarkable for its delicate shape, consisting of a number of slightly branched gracefully beading filaments superimposed like the leaves of a palm on a long transparent stalk. (See Bosc, in *Quart. Journ. Microsc. Sci.*, 1881, for further details.)

the matter is referred to the works of Busk (9), Hincks (10), Smitt (11), and Hillebrand (12). See also Ehlers (13) on Hypophorella.

## Sub-class 2. Entoprocta, Nitsehe.

Eupolyzoa in which the anal aperture lies close to the mouth within the tentacular area or lophophore. Lophophore sunk within a shallow basin formed by the inversion of the broad truncated extremity of the cup-shaped body. Tentacular crown not further introversible, the individual tentacles (as in the Pterobranchia and unlike the Ectoprocta) capable of being flexed and partially rolled up so as to overhang the mouth (see fig. 15, B and C). Body-cavity (coelom) almost completely obliterated. The antitentacular region of the polypide's body is drawn out to form a stalk similar to the gymnocaulus of the Pterobranchia. The extremity of this stalk is provided with a cement gland in the young condition which persists in the adult of some species (*Loxosoma neapolitanum*, fig. 16, shs). Cuticular investment (zoecium) of the polypides feebly developed. A pair of small nephridia are present.

The Entoprocta consist of the marine genera Pedicellina (fig. 15), *Loxosoma* (fig. 16), and probably the

FIG. 15.—A. Two polypides and buds of *Pedicellina belgica*, Van B. (after Van Beneden); greatly magnified. a, the polypide-stalk of a fully developed polypide; c, that of a less mature individual; b, a bud. All are connected by a common stalk or stolon. B. and C. Two views of the body of the polypide of *Pedicellina* (after Allman). a, cuticle; b, body-wall; c, permanently introverted anterior region of the body; d, margin of the tentacular cup or calyx thus formed; e, mouth; f, pharynx; g, stomach; h, intestine; i, anus; k, epistome or pre-oral lobe; l, nerve-ganglion; m, gonad; n, retractor muscle of the lophophore; o, lophophore.

insufficiently known freshwater American genus *Urnatella* of Leidy. To these must be added Busk's new genus *Ascopodaria*, as yet undescribed, based on a specimen dredged by the "Challenger," showing a number of *Pedicellina*-like polypides, carried as an umbel on a common stalk of very peculiar structure. *Pedicellina* is found attached to algæ, shells, zoophytes, &c., and to the integument of some Gephyræan worms (*Sipunculus punctatus*) and Annelids (*Aphrodite*); *Loxosoma* occurs on various worms, &c. Whilst the buds of *Pedicellina* remain connected so as to constitute a colony, those produced by *Loxosoma* are continually detached, so that the polypide is solitary. Further, the cup-like body of *Pedicellina* is deciduous, and frequently falls from the stalk and is replaced by new growth. There is less distinction between body and stalk in *Loxosoma*, and the former does not become detached. Apparently a very important feature in the structure of the Entoprocta is the absence of a body-cavity. This is, however, more apparent than real. The Entoprocta are true Coelomata, but the coelom is partially obliterated by the growth of mesoblastic tissue. The nephridia presumably lie in a space which, small as it is, represents the coelom. See Harmer (18) for details.

*Genealogical Relationships of the Groups of Polyzoa.*

It is necessary that we should try to form some opinion as to which of the various groups of Polyzoa are most like the ancestral form from which they have all sprung, and what are the probable lines of descent within the group. Any attempt of the kind is speculative, but it is absolutely needful since zoology has become a science—that is to say, an investigation of causes and not merely a record of unexplained observations—to enter upon such questions. Colonial organisms have necessarily descended from solitary ancestors, and it is probable that the ancestral form of Polyzoa was not only solitary, as are *Phoronis* and *Loxosoma* at the present day, but of relatively large size and more elaborately organized than the majority of living Polyzoa. Whilst the polypides have dwindled in size and

FIG. 15.—Diagram of *Loxosoma Neapolitanum* (after Kowalewsky). A single polypide devoid of buds. *m*, mouth; *st*, stomach; *shs*, buccal gland of the polypide stalk.

lost some of their internal organs, the modern Polyzoa have developed *pari passu* with this degeneration an elaborate system of bud-production and colony-formation. The new individuality (the tertiary aggregate) attains a high degree of development (*Cristatella*, *Kinetoskias*) in proportion as the constituent units merged in this new individuality have suffered a degeneration. The præ-oral lobe (epistome, buccal disk) present in all Polyzoa except the most minute and most elaborately colonial forms—namely, the *Gymnolæma*—is to be regarded as an ancestral structure which has been lost by the *Gymnolæma*. The horse shoe shaped lophophore, such as we see it in *Phoronis* and in *Lophopus*, is probably the ancestral form, and has given rise to the two other extreme forms of lophophore, namely, the “pterobranchiate,” associated with a great development of the epistome, and the “circular,” associated with a complete suppression of the epistome. The entoproctous lophophore is a special modification of the horse-shoe-shaped, as shown in the diagram fig. 15, C. The formation of zoecia, and so of an elaborate colonial

skeleton, was not a primary feature of the Polyzoa. Even after budding and colony-formation had been established zoecia were not at once produced, but possibly dwellings of another kind (*Pterobranchia*). We are thus led to look upon the *Gymnolæma* as the extreme modification of the Polyzoon type. Starting with an organism similar to *Phoronis*, we may suppose the following branchings in the pedigree to have occurred.

VERMIFORMIA

- A. The complete hippocrepian lophophore becomes specialized in the form of ctenidia or gill-plumes; the epistome enlarged.  
= *PTEROBRANCHIA*.
- B. The complete hippocrepian lophophore retains its form, but acquires a gradually increasing power of being telescoped into the hinder part of the body.  
= The Pro-Eupolyzoon.
- a. The anti-tentacular region of the body elongated as a stalk gives rise to one or two rapidly detached buds (*Cephalodiscus*).
- ß. The stalk gives rise to buds which do not detach themselves, but remain in continuity so as to form a colony of a hundred or more individuals (*Rhabdopleura*).
- A. The anti-tentacular region of the body becomes stalk-like, and develops buds which either detach themselves as they form (*Loxosoma*) or remain to form a small colony (*Pedicellina*). The telescopic introversibility of the lophophore does not advance beyond an initial stage. The arms of the lophophore grow round so as to embrace the anus.  
= Sub-class 1 (of the Eupolyzoa) Entoprocta.
- B. The complete hippocrepian lophophore remains in its original form, and also the præ-oral epistome, but the telescopic introversibility of the anterior region of the body is greatly developed at the same time that the cuticle of the hinder part of the body is increased in thickness and toughness. Bud production, not from a stalk-like pedicle, but from all parts of the body, now becomes characteristic, the buds, which were at first deciduous, now remaining in permanent continuity so as to form colonies.  
= The Pro-Ectoprocton.
- A. The polypides acquire the property of carrying their young so as to avoid the disastrous influences of finvatile currents, and also the property of producing resistant statoblasts, and thus are enabled to become isolated and to persist in the peculiar conditions of fresh waters.  
= The 1st order (of Ectoprocta) Phylactolæma.
- B. The polypides forming relatively larger colonies, and themselves becoming relatively more minute, lose by atrophy the præ-oral opistome; and simultaneously the arms of the hippocrepian lophophore dwindle, and a simple circum-oral areolet of tentacles is the result. The cuticle of the hinder part of the polypide becomes more and more specialized as the cell or zoecium, and in different polypides in various parts of the colony acquires special forms—as egg-cases, snappers (avicularia), tentacles, stalk and root segments.  
= The 2d order (of Ectoprocta) *Gymnolæma*.

*Distinctive Characters of the Polyzoa.*

From all that has preceded it appears that the really distinctive characters common to all the Polyzoa may be summed up as follows:—

Cœlomata with closely approximated mouth and anus, the bulk of the body forming a more or less elongate growth at right angles to the original (ancestral) oro-anal axis, and starting from the original ventral (i.e., oral) surface. A variously modified group of ciliated tentacles is disposed around the mouth, being essentially the development by digitiform upgrowth of a post-oral ciliated band.

As negative characters it is important to note the absence of all trace of metameric segmentation, of setae, and of paired lateral (parapodia of Appendiculata) or median ventral (podium of Mollusca) outgrowths of the body-wall.

#### Larval Forms of Polyzoa.

In the consideration of the probable pedigree and affinities of the Polyzoa, we are not at present able to make use of the facts of development from the egg, on account of the extreme difficulty which the study of the young stages of these organisms presents. In the case of Phoronis we have the only readily intelligible history. The larva, to start with, is of that form known as an archi-troch (see Lankester, "Notes on Embryology and Classification," *Quart. Journ. Micr. Sci.*, 1876), having a pre-oral ciliated area (velum or oesphalotroch) continuous with a post-oral ciliated band (the branchiotroch), which latter becomes developed into the tentacular crown of the adult.

The actinotrocha (Phoronis) larva is readily comparable with the trochosphere larvæ of Echinoderms, Chetopoda, Gephyreans, and Molluscs. Its special character consists in the strong development of the post-oral ciliated band, whereas the pre-oral ciliated band is in most other classes (the Sipunculoidea excepted) the predominant one. The Phoronis larva exhibits first of all an oro-anal long axis, and this is suddenly abandoned for a new long axis by the growth of the ventral surface of the larva at right angles to the primary axis (hence the term Podaxonia).

In the other Polyzoa we do not at present know of any larva which retains even in its earliest phases the original oro-anal long axis. They all appear to start at once with the peculiar and secondary long axis of the adult Phoronis, so that Balfour has diagrammatically represented the Polyzoon larva by the sketch given in fig. 19. This diagram applies, however, more especially to the Entoprocta, since the anus is represented as included in the area of the post-oral ciliated ring. The development of Pedicellina has been very carefully followed by Hatschek, and may be said to be

Fig. 17.

Fig. 17.—Larva of *Pedicellina* (from Balfour, after Hatschek). *v*, vestibule (the cup-like depression of the tentaculiferous end of the body); *m*, mouth; *i*, digestive gland; *an.i*, anal invagination; *fg*, the ciliated disk (corresponding to the cement gland of *Loxosoma* (fig. 16, *ahs*); *x*, so-called "dorsal organ," supposed by Balfour to be a bud, by Haeckel (18) regarded as the cephalic ganglion.

Fig. 18.

Fig. 18.—Later stage of the same larva as fig. 17. Letters as before, with the addition of *nph*, duct of the right nephridium; *a*, anus; *hg*, hind-gut.

the only instance among the Entoprocta in which the growth of the different organs and the consequent relation of the form of the larva to the form of the adult is understood (see figs. 17 and 18).

In the other Polyzoa, in spite of the painstaking and minute studies of Barrois (14), the fact is that we do not know what face of the larva corresponds to the tentacular axis, what to the stalk or anti-tentacular extremity, what to the anterior and what to the posterior surface. The conversion of the larva into the first polypide has not been observed in the case of these free-swimming forms, and it is even probable that no such conversion ever takes place, but that the first polypide forms as a bud upon the body-wall of the larva.

Two of the most remarkable forms of free-swimming larvae of Gymnolenæa are represented in figs. 20 and 21. In both, attention to the chief post-oral ciliated band, a smaller ciliated ring is observed, which is identified by Balfour with that which is found at the anti-tentacular extremity (base of the stalk) in the *Pedicellina* larva.

Fig. 19.—Diagram of an ideal Polyzoon larva (from Balfour). *an*, anus; *m*, mouth; *st*, stomach; *s*, ciliated disk (*fg* in figs. 17, 18, and 21).

It does not seem justifiable, in the face of the existing uncertainties as to identification of parts, and in view of the high probability that the Gymnolenæa are extremely modified and degenerate forms (a consideration which applies in some respects even more strongly to the Entoprocta), to assume that the larval form schematized in fig. 19 represents an ancestral condition of the Polyzoa. Professor Balfour (16) was, however, led to entertain such a view; and, assuming that the chief ciliated band (drawn as a broad black line) corresponds to the single pre-oral ciliated band of the trochosphere larva of Echinura, Polygordius, Chetopoda, and Mollusca, he pointed out that in both cases the ciliated girdle divides the larva into a hemisphere in which mouth and anus lie and a hemisphere which is the complement of this; in most classes the first hemisphere elongates and forms the bulk of the body, whilst the second hemisphere forms the prostomium or pre-oral lobe. But, according to Balfour's theory, in Polyzoa it is the second hemisphere which enlarges and becomes the stalk-like body of the adult, whilst the first hemisphere remains small and insignificant. Thus the Polyzoa would fix themselves in later growth by what corresponds to the head or prostomium of other animals, as do the Barnacles and the Aseidians. Ingenious as this speculation is, we must remember that it takes no account of the facts known as to Phoronis, nor of the Pterobranchia, and that it is confessedly based upon the assumption that the larvæ of extremely degenerate and peculiar members of the group are not adaptive and modified, but retain primary and archaic characters. Further, it is to be distinctly borne in mind that the interpretation of parts upon which this speculation rests is, except in the case of *Pedicellina*, altogether, hypothetical.

Fig. 20.—Larva of *Aleyonidium mytili* (from Balfour, after Barrois). *m*, mouth; *st*, oral invagination (?); *s*, Harmer's cephalic ganglion; *a*, ciliated disk (corresponding to *fg* in figs. 17, 18, and 21).

Fig. 21.—Larva of *Membranipora* (known as *Cyphonautes*). *m*, mouth; *a*, anus; *fg*, ciliated body; *x*, problematical body, supposed by Balfour to be a bud, similar to the dorsal organ *x* in figs. 17, 18, and to either *st* or *m* in fig. 20.

#### Relations of the Polyzoa to the Brachiopoda.

The Polyzoa were first associated with the Brachiopoda by H. Milne-Edwards. The investigation of the development of *Terebratulina* by Morse (16) led to a further perception of the points of agreement in structure between these two groups. Lastly, Caldwell (6) has shown that the mesenteries of Phoronis have precisely similar relations to the lophophore, the nephridia, and the termination of the intestine as have the gastro-parietal and ilio-parietal bands or mesenteries of the *Terebratulidae*. The young *Terebratulina* (fig. 22) may be readily compared with *Loxosoma* (fig. 16),—the peduncle with its cement glands in the former being identical with the stalk and basal gland of the latter. The form of the alimentary canal

Fig. 22.—Young *Terebratulina* at a stage when only six tentacles are present. *se*, setae at the margin of the calyx; *p*, stalk comparable to the stalk of *Pedicellina*, *Loxosoma*, *Cephalodiscus*, and *Rhabdopleura*; *pa*, cement gland at the apex of the stalk (after Morse).

may be readily compared with *Loxosoma* (fig. 16),—the peduncle with its cement glands in the former being identical with the stalk and basal gland of the latter. The form of the alimentary canal

and the disposition of the tentacular arms (fig. 23) is the same in Brachiopoda and Polyzoa. The nephridia (oviducts) of *Terebratulina* have a position and relations similar to those of the nephridia (genital ducts) of *Phoronis*. The chief difference between Polyzoa and Brachiopoda consists in the special development of the margin of the cupped end of the body, into which the lophophore is sunk, as in *Pedicellina* (see fig. 15, B, c). This up-standing margin is enormously

Fig. 23.

Fig. 24.

Fig. 23.—Lophophore and epistome of young *Terebratulina*, showing the horseshoe shape; the arms are turned in the direction the reverse of that taken by the lophophore-arms in Polyzoa (see fig. 4). In later growth they will become spirally coiled. (After Morse.)

Fig. 24.—Larva of the Brachiopod *Argiope* (from Gegenbaur, after Kowalewsky). m, setigerous lobe; b, setae; d, enteron.

increased in the Brachiopoda, so as to form a voluminous hood or collar, which surrounds the large tentacular arms, and forms a protective chamber for them. It is notched right and left so as to be divided into two lobes, and on its surface is developed a horny or a calcareous shell in two corresponding moieties. Until recently it was held (see Lankester, 17) that both Brachiopoda and Polyzoa were modifications of the Molluscan type, and the Brachiopods' collar was identified with the pallial fold of Mollusca. The resemblance of the two structures must now be considered as purely homoplastic, and not as having any real morphological (homogenetic) significance.

The larvæ of the Brachiopoda (figs. 24, 25) are as exceptional and difficult of interpretation as those of Polyzoa, but no attempt has been yet made to show that the one can be reduced to a common form with the other. The three segments presented by some Brachiopod larvæ (fig. 25) have been compared to the segments of *Chaetopod* worms by some writers; and these, together with the

presence of setae, have been regarded as indicative of affinity between the Brachiopoda and *Chaetopoda* (Morse). But it is sufficient, in order to dispose of this suggestion, to point out that the segments of the *Chaetopoda* follow one another along the primary oro-anal axis, whilst those of Brachiopoda are developed along an axis at right angles to this (Caldwell).

The Brachiopoda must be classified together with the Polyzoa

Fig. 25.—Surface views of ten stages in the development of *Terebratulina*, showing the free-swimming larva and its mode of fixation (after Morse). c, lophophoral segment; th, thoracic segment; p, peduncular segment; ds, deciduous setae.

and Sipunculoidæ in a phylum (Podaxonia) characterized by the development of this secondary axis.

POMBAL, SEBASTIAN JOSEPH DE CARVALHO E MELLO, MARQUIS DE (1699-1782), the greatest statesman Portugal has produced in modern times, was the son of a fairly wealthy country gentleman, Emmanuel de Carvalho, and was born at Soure, near Pombal, on 13th May 1699. He was educated at the university of Coimbra, and was then for a short time in the army, but it was not until he was nearly forty and had been married some years that he received his first public appointment, and was sent as minister to London in 1739. There he studied English administration, but never learnt the English language, and was promoted to the embassy at Vienna by King John V. in 1745, and recalled in 1750 to become minister for foreign affairs. Before he reached Lisbon John was dead, and his successor King Joseph at once placed entire confidence in him. He soon began to show his strength: in 1751 he checked the Inquisition, by allowing no executions without the royal permission; he improved the navy, the police, and the finances, and freed the Indians of the Brazils from slavery. The great earthquake of Lisbon on 1st November 1755 showed him in his true greatness; when the king asked him despairingly what he should do, he answered briefly, "Bury the dead and feed the living," and by his calmness at that frightful moment gained an ascendancy over the royal mind which lasted till Joseph's death. His power was at once used to check the Roman Catholic Church, which, with the Jesuits and the Inquisition, had eaten the life out of the country, and in 1757 the Jesuits were expelled from court (see JESUITS, vol. xiii. p. 654). The

Count d'Oeyras, as he was now made, then devoted himself to internal administration; he founded the Oporto Wine Company, encouraged sericulture, rebuilt Lisbon, and improved on the Jesuit system of education, and in 1762 showed his concurrence in the hereditary policy of Portugal in helping England against Spain, when the Family Compact had united the interests of Spain and France. On the 3rd September 1769 an attempt on the king's life was frustrated by the count, who was in 1770 made marquis of Pombal. He remained in power till the death of the king in 1777, but the new sovereign, Queen Maria, at once accepted his resignation, and persecuted him till his death in 1782.

**POMEGRANATE.** The pomegranate (*Punica Granatum*) is of exceptional interest by reason of its structure, its history, and its utility. It forms a tree of small stature, or a bush with opposite, shining, lance-shaped leaves, from the axils of some of which proceed the brilliant scarlet flowers. These are raised on a short stalk, and consist of a thick fleshy cylindrical or bell-shaped calyx tube, with five to seven short lobes at the top. From the throat of the calyx proceed five to seven roundish, crumpled, scarlet or crimson petals, and below them very numerous slender stamens. The pistil consists of two rows of carpels placed one above another, both rows embedded in, and partially inseparable from, the inner surface of the calyx tube. The styles are confluent into one filiform thread. The fruit, which usually attains the size of a large orange, consists of a hard leathery rind, which is the enlarged calyx tube,

enclosing a quantity of pulp derived from the coats of the numerous seeds. This pulp, filled as it is with refreshing acid juice, constitutes the chief value of the tree. The more highly cultivated forms contain more of it than the wild or half-wild varieties. The great structural peculiarity consists in the presence of the two rows of carpels one above another (a state of things which occurs exceptionally

Fig. 1.

Fig. 2.

Transverse sections of the lower and upper parts of the berried fruit of the Pomegranate.

in apples and oranges), and in the fact that, while in the lower series (fig. 1) the seeds are attached to the inner border or lower angle of the cavity, they occupy the outer side in the upper series (fig. 2), as if, during growth, the upper whorl had become completely bent over.

By Bentham and Hooker the genus *Punica* is included under *Lythraceæ*; others consider it more nearly allied to the myrtles; while its peculiarities are so great as, in the opinion of many botanists, to justify its inclusion in a separate order. Not only is the fruit valuable in hot countries for the sake of its pulp, but the rind and the bark and the outer part of the root are valuable as astringents owing to the large quantity of tannin that they contain. The bark of the root is likewise valued in cases of tape-worm.

The tree is without doubt wild in Afghanistan, north-western India, and the districts south and south-west of the Caspian, but it has been so long cultivated that it is difficult to say whether it is really native in Palestine and the Mediterranean region. It has been cited as wild in northern Africa, but this appears to be a mistake. Recently, however, Prof. Bayley Balfour met with a wild species, heretofore unknown, in the island of Socotra, the flowers of which have only a single row of carpels, which suggests the inference that it may have been the source of the cultivated varieties. But, on the other hand, in Afghanistan, where Aitchison met with the tree truly wild, a double row of carpels was present as usual. The antiquity of the tree as a cultivated plant is evidenced by the Sanskrit name *Dālimba*, and by the references to the fruit in the Old Testament, and in the *Odyssey*, where it is spoken of as cultivated in the gardens of the kings of Phœacia and Phrygia. The fruit is frequently represented on ancient Assyrian and Egyptian sculptures, and had a religious significance in connexion with several Oriental cults, especially the Phrygian cult of Cybele (Arnob., v. 5 sq.; see also Baudissin, *Studien*, ii. 207 sq.). It was well known to the Greeks and Romans, who were acquainted with its medicinal properties and its use . . . erial. The name given by the Romans, *malum* . . . that they received it from Carthage, as indeed is expressly stated by Pliny; and this circumstance has given rise to the notion that the tree was indigenous in northern Africa. On a review of the whole evidence, botanical, literary, and linguistic, Alphonse de Candolle (*Origine des Plantes Cultivées*) pronounces against its African origin, and decides in favour of its source in Persia and the neighbouring countries. According to Saporta the pomegranate existed in a fossil state in beds of the Pliocene epoch near Meximieux in Burgundy. The pomegranate is sometimes met with in cultivation against a wall in England, but it is too tender to withstand a severe winter. The double-flowered varieties are specially desirable for the beauty and long duration of their flowers.

POMERANIA (Germ. *Pommern*) is a maritime province of Prussia, bounded on the N. by the Baltic, on the W. by Mecklenburg, on the S. by Brandenburg, and on the E. by West Prussia. Its area is 11,620 square miles. The province is officially divided into the three districts of Stralsund, Stettin, and Cöslin; but more historical interest attaches to the names of Vorpommern and Hinterpommern, or Hither and Farther Pomerania, applied to the territory to the west and to the east of the Oder respectively. As a whole Pomerania is one of the lowest and flattest parts of Germany, . . . to the east of the Oder it is traversed by a range of low hills, and there are also a few isolated eminences to the west. Off the west coast, which is very irregular, lie the islands of Rügen, Usedom,

and Wollin; the coast of Farther Pomerania is smooth in outline and bordered with dunes or sandbanks. Besides the Oder and its affluents, there are several small rivers flowing into the Baltic, none of which, however, are navigable except for rafts. Many of these end in small littoral lakes, separated from the sea by a narrow strip of land, through which the water escapes by one or more outlets. The interior of the province is also thickly sprinkled with lakes, the combined area of which is equal to about one-twentieth of its entire surface. The soil of Pomerania is for the most part thin and sandy, especially to the east of the Oder; but patches of good soil occur here and there. About 55 per cent. of the surface is under tillage, while 19 per cent. consists of meadow and pasture and 20 per cent. is covered by forests. The principal crops are potatoes, rye, and oats, but wheat and barley are grown in the more fertile districts; tobacco and beetroot for sugar are also cultivated. Agriculture is still in many respects carried on in a somewhat primitive fashion, and the live stock is as a rule of an inferior quality. Large flocks of sheep are kept both for their flesh and wool, and geese and goose-feathers form lucrative articles of export. (A tabular view of the agricultural products of Pomerania will be found under PRUSSIA.) Owing to the long coast-line and the numerous lakes, fishing forms a not unimportant industry, and large quantities of herring, eels, lampreys, &c., are sent from Pomerania to other parts of Germany. With the exceptions of its inexhaustible layers of peat or soft coal, the mineral wealth of Pomerania is insignificant. Its industrial activity is also of no great importance, though there are a few manufactories of machinery, chemicals, tobacco, sugar, and other articles, chiefly in or near the larger towns, and linen-weaving is practised as a domestic industry. Shipbuilding is carried on at Stettin and other places on the coast. Commerce, however, is relatively much more flourishing. Stettin is one of the chief sea-ports of Prussia, and Stralsund, Greifswald, and Colberg also possess a foreign trade, the exports consisting mainly of grain, timber, and fish.

In 1880 Pomerania contained 1,540,034 inhabitants, all of whom were Protestants except 23,877 Roman Catholics and 13,886 Jews. The Slavonic element in the population is now represented only by a few thousand Poles and a handful of the ancient Cassubians on the east border. Pomerania is the most sparsely populated province in Prussia, the ratio being 132 inhabitants per square mile. About 67 per cent. of the population belong to the rural districts, while the remainder live in communities of 2000 and upwards. There are only nine towns with more than 10,000 inhabitants, at the head of which stands Stettin with 91,000. The Pomeranians belong mainly to the old Saxon stock, and are, as a rule, tall, strong, and well-built. They somewhat resemble the Scots in their cautious and persevering character, their strong theological bias (which perpetuates the existence of numerous small Protestant sects), and their turn for dry humour; but they are by no means so enterprising or so open to new ideas. In 1883 only 0.32 per cent. of the Pomeranian recruits were illiterate, a fact which speaks well for the educational system of the province. There is a university at Greifswald. The province sends 16 members to the reichstag and 26 to the Prussian house of representatives. The heir-presumptive of the Prussian crown bears the title of governor of Pomerania.

*History.*—In prehistoric times the southern coast of the Baltic seems to have been occupied by Celts, who afterwards made way for tribes of Teutonic stock. These in their turn migrated to other settlements and were replaced, about the beginning of the 6th century of our era, by Slavonians. The name of Pomore or Pommern, meaning "on the sea," was attached to the district by the last of these immigrant races, and has often changed its political and geographical significance. Originally it seems to have denoted the coast district between the Oder and the Vistula, a territory which was at first more or less dependent on Poland, but which appears towards the end of the 12th century as divided between two native dukes owning the supremacy of the German emperor. Afterwards Pomerania spread much farther to the west, while correspondingly curtailed on the east, and a distinction was made between Slavonia, or modern Pomerania, and Pomerellen. The latter, corresponding substantially to the present province of West

Prussia, remained subject to Poland down to the beginning of the 14th century, when part of it fell away to the Teutonic knights and part of it was annexed to the duchy of Pomerania-Wolgast. Christianity was introduced in the 12th century, and its advance went hand in hand with the Germanizing of the district. The later medieval history of Pomerania is occupied with an endless succession of subdivisions among different lines of the ducal houses, and with numerous expansions and contractions of territory through constant hostilities with the elector of Brandenburg, who claimed to be the immediate feudal superior of Pomerania, and with other neighbouring powers. The names Vorpommern and Hinterpommern were at first synonymous with Slavonia and Pomerellen, but towards the close of the 14th century they were transferred to the two duchies into which the former (Pomerania proper) was divided. In 1625 the whole of Pomerania became united under the sway of Bogislaus XIV., and, on his death without issue in 1637, Brandenburg laid claim to the duchy in virtue of a compact of 1571. The Swedes, however, had in the meantime occupied the country, and at the peace of Westphalia (1648) the elector had to content himself with East Pomerania and see the other half awarded to Sweden. In 1720 Swedish Pomerania was curtailed by extensive concessions to Prussia, but the district to the west of the Peene remained in possession of Sweden down to the dissolution of the German empire. On the downfall of Napoleon, Sweden assigned her German possessions to Denmark in exchange for Norway, whereupon Prussia, partly by purchase and partly by the cession of Lauenburg, finally succeeded in uniting the whole of Pomerania under her sway.

**POMEROY**, a city of the United States, in Meigs county, Ohio, lies on the right bank of the Ohio about half-way between Pittsburgh and Cincinnati. It is the terminus of the Ohio River division of the Columbus, Hocking Valley, and Toledo Railway, and has extensive coal-mines dating from 1833, salt works (14,000,000 bushels per annum), and bromine factories. Incorporated as a village in 1841 and as a city in 1868, Pomeroy had 5824 inhabitants in 1870 and 5560 in 1880.

**POMFRET**, JONAS (1667–1703), holds a certain place in English letters as the author of a short poem, *The Choice*, which embodies in easy and happy Drydenic diction the refined Epicureanism of the 18th century, and was consequently widely popular throughout that century. Pomfret was an English clergyman, rector of Maulden in Bedfordshire, son of the vicar of Luton in the same county. The story is preserved by Johnson that the bishop of London stopped him in some church preferment because in his *Choice* he declared that he would have no wife, although he expressed a wish for the occasional company of a modest and sprightly young lady. The poet was married in real life all the same, and, while waiting in London to clear up a misunderstanding caused by the paganism of his poetry—the bishop apparently thinking that he had openly preferred a mistress to a wife—he caught small-pox and died at the age of thirty-five. Of his poetry Johnson happily says, “He pleases many; and he who pleases many must have some species of merit.”

**POMONA**, the old Roman goddess of tree-fruits (*poma*). Ovid (*Met.*, xiv. 623 *sq.*) tells how she was loved by the silvan deities, the satyrs, pans, &c., and how Vertumnus, god of the turning year, wooed and won the shy goddess. Corresponding to Pomona there seems to have been a male Italian deity called Pomunus, who was perhaps identical with Vertumnus. At Rome Pomona had a special priest, the flamen Pomonalis, who ranked lowest among the fifteen flamens. About 12 miles from Rome on the way to Ostia there was a Pomonal, or place (perhaps grove) sacred to Pomona. She was also worshipped in the neighbourhood of Amiternum.

**POMPADOUR**, JEANNE ANTOINETTE POISSON LE NORMANT D'ÉTOILES, MARQUISE DE (1721–1764), the most famous of all the mistresses of Louis XV., was born in Paris on 29th December 1721, and was baptized as the legitimate daughter of François Poisson, an officer in the household of the duke of Orleans, and his wife Madeleine de la Motte, in the church of St Eustache, but she was suspected, as well as her brother, afterwards marquis of

Marigny, to be the child of a very wealthy financier, and farmer-general of the revenues, Le Normant de Tournem. He at any rate took upon himself the charge of her education; and, as from the beauty and wit she showed from childhood she seemed to be born for some uncommon destiny, he declared her “un morceau de roi,” and specially educated her to be a king's mistress. This idea was confirmed in her childish mind by the prophecy of an old woman, whom in after days she pensioned for the correctness of her prediction. In 1741 she was married to a nephew of her protector and guardian, Le Normant d'Étoiles, who was passionately in love with her, and soon became a queen of fashion. Yet the world of the financiers at Paris was far apart from the court world, where she wished to reign; she could get no introduction at court, and could only try to catch the king's eye when he went out hunting. But Louis XV. was then under the influence of Madame de Mailly, who carefully prevented any further intimacy with “la petite Étoiles,” and it was not until after her death that the king met the fair queen of the financial world of Paris at a ball given by the city to the dauphin in 1744, and he was immediately subjugated. She at once gave up her husband, and in 1745 was established at Versailles as “maîtresse en titre.” Louis XV. bought her the estate of Pompadour, from which she took her title of marquise. She was hardly established firmly in power before she showed that ambition rather than love had guided her, and began to mix in politics. Knowing that the French people of that time were ruled by the literary kings of the time, she paid court to them, and tried to play the part of a Mæcenæ. Voltaire was her poet in chief, and the founder of the physiocrats, Quesnay, was her physician. In the arts she was even more successful; she was herself no mean etcher and engraver, and she encouraged and protected Vanloo, Boucher, Vien, Greuze, and the engraver Jacques Guay. Yet this policy did not prevent her from being lampooned, and the famous Poissardes against her contributed to the ruin of many wits suspected of being among the authors, and notably of the Comte de Maurepas. The command of the political situation passed entirely into her hands; she it was who brought Belle-Isle into office with his vigorous policy; she corresponded regularly with the generals of the armies in the field, as her recently published letters to the Comte de Clermont prove; and she introduced the Abbé de Bernis into the ministry in order to effect a very great alteration of French politics in 1756. The continuous policy of France since the days of Richelieu had been to weaken the house of Austria by alliances in Germany; but Madame de Pompadour changed this hereditary policy because Frederick the Great wrote scandalous verses on her; and because Maria Theresa wrote her a friendly letter she entered into an alliance with Austria. This alliance brought on the Seven Years' War with all its disasters, the battle of Rosbach and the loss of Canada; but Madame de Pompadour persisted in her policy, and when Bernis failed her, brought Choiseul into office, and supported him in all his great plans, the Pacte de Famille, the suppression of the Jesuits, and the peace of Versailles. But it was to internal politics that this remarkable woman paid most attention; no one obtained office except through her; in imitation of Madame de Maintenon she prepared all business for the king's eye with the ministers, and contrived that they should meet in her room; and she daily examined the letters sent through the post office with Janelle, the director of the post office. By this continuous labour she made herself indispensable to Louis. Yet, when she had lost the heart of her lover after a year or two she had a difficult task before her; to maintain her influence she had not only to save the king as much trouble as possible, but to find him fresh pleasures. When he first

began to weary of her, she remembered her talent for acting and her private theatricals at Étioles, and established the "théâtre des petits cabinets," in which she acted with the greatest lords about the court for the king's pleasure in tragedies and comedies, operas and ballets. By this means and the "concerts spirituels" she kept in favour for a time; but at last she found a surer way, by encouraging the king in his debaucheries, and Louis wept over her kindness to his various mistresses. Only once, when the king was wounded by Damiens in 1757, did she receive a serious shock, and momentarily left the court; but on his recovery she returned more powerful than ever. She even ingratiated herself with the queen, after the example of Madame de Maintenon, and was made a lady-in-waiting; but the end was soon to come. "Ma vie est un combat," she said, and so it was, with business and pleasure; she gradually grew weaker and weaker, and when told that death was at hand she dressed herself in full court costume, and met it bravely on 15th April 1764 at the age of forty-two.

See Capéfigue, *Madame la Marquise de Pompadour*, 1858; E. and J. de Goncourt, *Les Maîtresses de Louis XV.*, vol. II., 1869; and Campardon, *Madame de Pompadour et la Cour de Louis XV. au milieu du dix-huitième siècle*, 1867. Far more valuable are Malassie's two recently published volumes of correspondence, *Correspondance de Madame de Pompadour avec son père M. Poisson, et son frère M. de l'Andière, &c.*, 1878, and Bonhomme, *Madame de Pompadour, général d'armée*, 1890, containing her letters to the Comte de Clermont. For her artistic and theatrical tastes see particularly J. F. Leturg, *Notice sur Jacques Guay, graveur sur pierres fines du Roi Louis XV.: Documents inédits émanant de Guay et notes sur les œuvres de gravure en taille douce et en pierres durs de la Marquise de Pompadour*, 1873; and Adolphe Jullien, *Histoire du Théâtre de Madame de Pompadour, dit Théâtre des Petits Cabinets*, 1874.

POMPEII, an ancient town of Campania, situated on the shore of the Bay of Naples, almost immediately at the foot of Mount Vesuvius. To its proximity to that volcano it owes its celebrity,—the peculiar circumstances of its destruction by the great volcanic outburst of Vesuvius in 79 A.D., and of its rediscovery in modern times, having converted that which would otherwise have been known only as an obscure country town into a place of world-wide fame, as one of the most interesting relics preserved to us from antiquity. Of its previous history comparatively little is recorded, but it appears that, like most other towns in the beautiful region in which it was situated, it had a population of a very mixed character, and it passed successively into the hands of several different nations, each of which probably contributed an additional element to its composition. Though its foundation was ascribed by Greek tradition to Heracles, in common with the neighbouring city of Herculaneum, no value can be attached to these mythological or etymological fables; it is certain that it was not a Greek colony, in the proper sense of the term, as we know to have been the case with the more important cities of Cumæ and Neapolis. Strabo, in whose time it was a populous and flourishing place, tells us that it was first occupied by the Oscans, afterwards by the Tyrrhenians (i.e., Etruscans) and Pelasgians, and lastly, by the Samnites. The conquest of Campania by the last-mentioned people is an undoubted historical fact, and there can be no doubt that Pompeii shared the fate of the neighbouring cities on this occasion, and afterwards passed in common with them under the yoke of Rome. But its name is only once mentioned during the wars of the Romans with the Samnites and Campanians in this region of Italy, and then only incidentally (Liv., ix. 38). At a later period, however, it took a prominent part in the outbreak of the nations of central Italy known as the Social War (91–89 B.C.), when it withstood a long siege by Sulla, and was one of the last cities of Campania that was reduced by the Roman arms. After that event the inhabitants were admitted to the Roman franchise, but a military colony was settled in their territory by the dictator Sulla, and there can be no doubt that the whole population became rapidly Romanized. Before the close of the

republic it became a favourite resort of the leading nobles of Rome, many of whom acquired villas in the neighbourhood. Among the most prominent of these was Cicero, whose letters abound with allusions to his Pompeian villa, which was one of his favourite places of occasional residence. The same fashion continued under the Roman empire, and there can be no doubt that during the first century after the Christian era, Pompeii, without rising above the rank of an ordinary provincial town, had become a flourishing place with a considerable population, for which it was indebted in part to its position at the mouth of the river Sarnus, which rendered it the port of the neighbouring towns in the interior. But two events only are recorded of its history during this period. In 59 A.D. a tumult took place in the amphitheatre of Pompeii between the citizens of the place and the visitors from the neighbouring colony of Nuceria, which led to a violent affray, in which many persons were killed and wounded on both sides. The Pompeians were punished for this violent outbreak by the prohibition of all gladiatorial and theatrical exhibitions for ten years (Tacitus, *Ann.* xiv. 17). A characteristic, though rude, painting, found on the walls of one of the houses, gives a representation of this untoward event.

Only four years afterwards (63 A.D.) a much more serious disaster befell the city. An earthquake, which affected all the neighbouring towns, vented its force especially upon Pompeii, a large part of which, including most of the public buildings, was either destroyed or so seriously damaged as to require to be rebuilt rather than repaired (Tacit., *Ann.* xv. 21; Seneca, *Q. N.*, vi. 1). The actual amount of the injuries sustained, which is intimated in general terms by Tacitus and Seneca, is more accurately known to us from the existing remains. For the inhabitants were still actively engaged in repairing and restoring the ruined edifices when the whole city was overwhelmed by a much more appalling catastrophe. In 79 A.D. the neighbouring mountain of Vesuvius, the volcanic forces of which had been slumbering for unknown ages, suddenly burst into a violent eruption, which, while it carried devastation all around the beautiful gulf, buried the two cities of Herculaneum and Pompeii under dense beds of cinders and ashes. It is singular that, while we possess a detailed description of this famous eruption in two well-known letters of the younger Pliny (*Epist.* vi. 16, 20), he does not even notice the destruction of Pompeii or Herculaneum, though his uncle perished in the immediate neighbourhood of the former city. But their unhappy fate is noticed by Dion Cassius, and its circumstances may be gathered with certainty from the condition in which it has been found. These were such as eminently to conduce to its preservation and interest as a relic of antiquity. Pompeii, was not, like Herculaneum, buried in a solid mass of volcanic tuff, but merely covered with a bed of lighter substances, cinders, small stones, and ashes, thrown out by the volcano, and falling from above on the devoted city. It is clearly established that the whole of this superincumbent mass, though attaining to an average thickness of from 18 to 20 feet, was the product of one eruption,—though the materials may be divided generally into two distinct strata, the one consisting principally of cinders and small volcanic stones (called in Italian "lapilli"), and the other and uppermost layer of fine white ash, often consolidated by the action of water from above, so as to take the moulds of objects contained in it like clay or plaster of Paris.

So completely was the unfortunate city buried under this overwhelming mass that its very site was forgotten, and even the celebrated topographer Cluverius in the 17th century was unable to fix it with certainty. This difficulty

arose in part from the physical changes consequent on the eruption, and it was not till 1748 that an accidental discovery drew attention to its remains, and revealed the fact that beneath the vineyards and mulberry grounds which covered the site there lay entombed the ruins of a city, far more accessible, if not more interesting, than those (previously discovered) of the neighbouring Herculaneum. It was not till 1755 that systematic excavations on the site were begun, and, though they were thenceforth carried on more or less continuously during the whole of that century, it was not till the beginning of the present century that they assumed a regular character; and the work, which had received a vigorous stimulus during the period of the French government (1806-1814), was prosecuted, though in a less methodical and systematic manner, under the succeeding rule of the Bourbon kings (1815-61). Of late years the process has been carried on, under the enlightened direction of Signior Fiorelli, in a much more careful and scientific manner than before, and the results have been in many respects of the highest interest. At the same time the invention of photography has enabled the directors to preserve a far more satisfactory record of every step in the explorations than could previously be attempted.

It would be impossible for us to present our readers in this place with anything like an idea of the results of these excavations. Interesting as are the numerous works of art that have been brought to light, and important as is their bearing upon the history of some branches of ancient art, they cannot compare in interest with the flood of light which this marvellous discovery has thrown upon ancient life in all its details, enabling us to picture to ourselves the ways and manners and habits of life of a cultivated and flourishing population eighteen centuries ago, in a manner which no amount of study of ancient literature could possibly accomplish. We must confine ourselves in the present article chiefly to those points which bear more immediately on the topography and character of the town of Pompeii, referring our readers for other details to the numerous works in which they have been described and delineated.

The town was situated on a rising ground of small elevation, separated by a distance of less than a mile from the foot of the actual rise of the outer cone of Vesuvius. This eminence is itself undoubtedly due to an outflow of lava from that mountain, during some previous eruption in prehistoric times, for we know from Strabo that Vesuvius, though presenting in his time all the appearances of an extinct volcano, had been quiescent ever since the first records of the Greek settlements in this part of Italy. But the position of Pompeii in ancient times differed materially from that which it occupies at the present day. It was situated close to the sea-shore, from which it is now more than a mile distant, and adjoining the mouth of the river Sarnus or Sarno, which now enters the sea nearly two miles from its site, but the present course of this stream is due in part to modern alteration of its channel, as well as to the effects of the great eruption. It is certain, however, that in Strabo's time Pompeii owed much of its prosperity to its serving as the port of the adjoining plain, and the neighbouring towns of Nuceria, Nola, and Acerræ (Strabo, v. c. 4, § 8).

The area occupied by the ancient city was of an irregular oval form, and about two miles in circumference. It was surrounded by a wall, which is still preserved around more than two-thirds of its extent, but no traces of this are found on the side towards the sea, and there is no doubt that on this side it had been already demolished in ancient times, so as to give room for the free extension of houses and other buildings in that direction. These walls are strengthened at intervals by numerous towers, which occur in some parts at a distance of only about 100

yards, but in general much less frequently. They are, however, of a different style of construction from the walls, and appear to have been added at a later period, probably that of the settlement of the Roman colony by Sulla. Similar evidences of the addition of subsequent defences are to be traced also in the case of the gates, of which no less than eight are found in the existing circuit of the walls. Some of these present a very elaborate system of defence, but it is evident from the decayed condition of others, as well as of parts of the walls and towers, that they had ceased to be maintained for the purposes of fortification long before the destruction of the city. The gates are now known by names given them in modern times from the direction in which they led, as, the gate of Herculaneum, of Stabiae, of Nola, &c. No trace has been found of their ancient appellations.

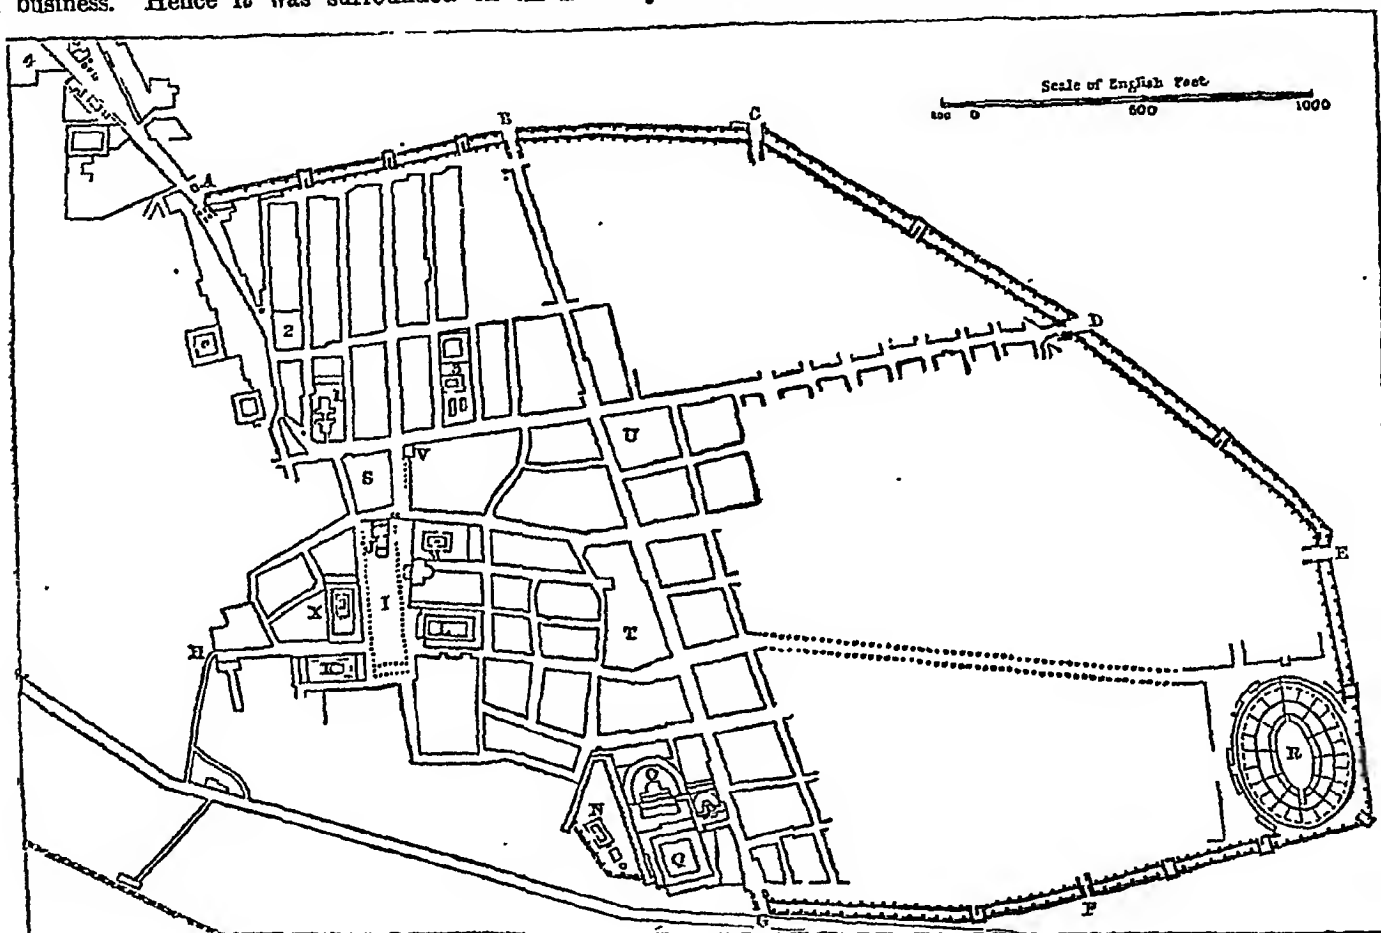

The general plan of the town is very regular, the streets being generally straight, and crossing one another at right angles or nearly so. But an exception is found in the street leading from the gate of Herculaneum to the forum, which, though it must have been one of the principal thoroughfares in the city, was crooked and irregular, as well as very narrow, in some parts not exceeding 12 to 14 feet in width, including the raised *trottoirs* or footpaths on each side, which occupy a considerable part of the space, so that the carriage-way could only have admitted of the passage of one vehicle at a time. The other streets are in some cases broader, but rarely exceed 20 feet in width, and the broadest yet found is less than 30, while the back streets running parallel to the main lines are only about 15 feet. They are uniformly paved with large polygonal blocks of hard basaltic lava, fitted very closely together, though now in many cases marked with deep ruts from the passage of vehicles in ancient times. They are also in all cases bordered by raised *trottoirs* on both sides, paved in a similar manner; and for the convenience of foot passengers, these are connected from place to place by stepping-stones raised above the level of the carriage-way. Such an arrangement must have presented a considerable obstacle to the passage of vehicles; and altogether it is evident that the streets of Pompeii, like those of most Roman towns, were calculated much more for foot passengers than for any extensive traffic of wheeled carriages. In other respects they must have been far from presenting the lively aspect of the streets of modern and even mediæval towns, and must rather have resembled those of Oriental cities,—the living apartments all opening towards the interior, and showing only blank walls towards the street; while the windows were generally to be found only in the upper story, and were in all cases small and insignificant, without any attempt at architectural effect. In some instances indeed the monotony of their external appearance was broken by small shops, occupying the front of the principal houses, as it were let in to the main building; these were in some cases numerous enough to form a continuous *façade* to the street. This is seen especially in the case of the Street of Herculaneum, and that of Stabiae, both of which were among the principal and most frequented thoroughfares.

The former of these main lines of street, which, as already described, led from the gate of Herculaneum to the forum, was crossed, a little before it reached that important centre, by a long straight line of street, which led directly to the gate of Nola. Two other parallel lines of street struck off from the forum itself towards the east, and these have been followed as far as the points where they cross nearly at right angles another main line of street, which leads direct from the gate of Vesuvius to that of Stabiae, near the theatres, thus traversing the city in its whole width from north to south. Almost the

whole portion of the city which lies to the west of this last line, towards the forum and the sea, has been more or less completely excavated; but the greater part of that on the other side of it remains still unexplored, with the exception of the amphitheatre, and a small space in its immediate neighbourhood. Altogether it may be calculated that about two-fifths of the whole extent has been already excavated. But there can be little doubt that the portion already known is the most important, as it includes the forum, with the temples and public buildings adjacent to it, the thermæ, theatres, amphitheatre, &c.

The forum was unquestionably at Pompeii, as at Rome itself, and in all other Italian cities, the focus and centre of all the life and movement of the city, and was at once the resort of the lounge and the gathering place of men of business. Hence it was surrounded on all sides by

public buildings or edifices of a commanding character. It was not, however, of large size, as compared to the open spaces in modern towns, being only 160 yards in length by 35 in breadth. Nor was it a centre of traffic in the modern sense of the word, being only accessible to any description of wheeled carriages at one angle, and the nature of its pavement, composed of broad flags of travertine, excluding the idea of its being intended for their passage. It was surrounded on three sides by a portico, or rather by a series of porticos, some supported on arcades, others in the Grecian manner on columns; and these porticos were originally surmounted by a gallery or upper story, traces of the staircases leading to which still remain, though the gallery itself has altogether disappeared. It is, however, certain from the existing remains that both this portico and the adjacent buildings

Plan of Pompeii.

had suffered severely from the earthquake of 63, and that they were undergoing a process of restoration, involving material changes in the original arrangements, which was still incomplete at the time of their final destruction.

The north end of the forum, where alone the portico is wanting, is occupied in great part by a building, the most imposing in the whole city, which is now generally known, on grounds that may be considered satisfactory, as the temple of Jupiter. It was raised on a *podium* or base of considerable elevation, and had a portico with six Corinthian columns in front, which, according to Sir W. Bell, are nearly as large as those in the portico of St Paul's. This magnificent edifice had, however, been evidently overthrown by the earthquake of 63, and is in its present condition a mere ruin. On each side of it were two arches, affording an entrance into the forum, but capable of being closed by iron gates. The principal

of these, at the north-east angle of the forum, was the approach by which that open space was entered in coming from the gate of Herculaneum; the passage, however, was barred to wheeled carriages by a descent of three small steps. On the east side of the forum were four edifices, all of them unquestionably of a public character, but of which the names and attribution have been the subject of much controversy. The first (proceeding from the north) is generally known, though without doubt erroneously, as the Pantheon, or temple of the Twelve Gods; but it is very doubtful whether it is a temple at all, and the latest authorities are disposed to regard it as a *macellum* or meat-market, though the situation would seem to be unhappily chosen for such a purpose. Next to this comes a building generally regarded as the *curia* or *senaculum*—the meeting-place of the local senate, or town council. Beyond this comes another temple of small

dimensions commonly called the temple of Mercury, but supposed also, on very slight grounds, to have been dedicated to Augustus; and beyond this again, bounded on the south by a street known as the Street of the Silver-smiths, is a large and spacious edifice, which, as we learn from an extant inscription, was erected by a priestess named Eumachia. Notwithstanding this, its purpose and character are open to considerable doubt; but it resembles a basilica in its form and disposition, and was probably designed for similar purposes. The name of Chalcidicum, by which it is commonly known, is an erroneous inference from the inscription just referred to. The south end of the forum is occupied by three small buildings of very similar form and arrangement, which are supposed to have served as courts of law, though their destination is a matter of much uncertainty; while the greater part of the west side is occupied by two large buildings,—a basilica, which is the largest edifice in Pompeii, and a temple, which presents its side to the forum, and hence fills up a large portion of the surrounding space. The former, as we learn from an inscription on its walls, was anterior in date to the consulship of M. Lepidus and Q. Catulus (78 B.C.), and therefore belongs to the Oscan period of the city, before the introduction of the Roman colony. The temple was an extensive edifice, having a comparatively small *cella*, raised upon a *podium*, and standing in the midst of a wide space surrounded by a portico of columns, outside which again is a wall, bounding the sacred enclosure. It is commonly called the temple of Venus, but without any evidence; the most recent authorities regard it, on somewhat better grounds, as dedicated to Apollo. Between this temple and the basilica a street of unusual width leads off direct to the gate which opens towards the sea, and is still preserved, though the walls on this side of the city have ceased to exist.

Besides the temples which surrounded the forum, the remains of four others have been discovered, three of which are situated in the immediate neighbourhood of the theatres. Of these by far the most interesting, though the least perfect, is one which is commonly known as the temple of Hercules (an appellation wholly without foundation), and which is not only by far the most ancient edifice in Pompeii, but presents us with all the characters of a true Greek temple, resembling in its proportions that of Neptune at Paestum, and probably of as remote antiquity. Unfortunately only the basement and a few capitals and other architectural fragments remain, and, though these suffice to enable us to restore its plan and design, of course its effect as a monument is wholly lost. The period of its destruction is unknown, for it appears certain that it cannot be ascribed wholly to the earthquake of 63. On the other hand the reverence attached to it in the later periods of the city is evidenced by its being left standing in the midst of a triangular space adjoining the great theatre, which is surrounded by a portico, so as to constitute a kind of forum, though scarcely deserving that appellation. In the immediate neighbourhood of the preceding, and close to the great theatre, stood a small temple, which, as we learn with certainty from the inscription still remaining, was dedicated to Isis, and was restored, or rather rebuilt, by a certain Popidius Celsinus, after the original edifice had been reduced to ruin by the great earthquake of 63. Though of small size, and by no means remarkable in point of architecture, it is interesting as the only remaining temple dedicated to the Egyptian goddess, whose worship became so popular under the Roman empire. There is nothing peculiar in the arrangements of the building itself, but a small edifice within the sacred enclosure, to which nothing similar was found in any other instance, was doubtless in some way connected

with the peculiar rites of the mysterious deity. Close to this temple was another, of very small size, and of little interest, commonly known as the temple of Æsculapius, but by others supposed to have been dedicated to Jupiter and Juno. No real foundation exists for either attribution. More considerable and important was a temple which stood at no great distance from the forum, at the point where the street leading thither from the gate of Herculaneum was crossed by the wide line of thoroughfare leading to the gate of Nola. We learn from an inscription that this was dedicated to the Fortune of Augustus (*Fortuna Augusta*), and was erected, wholly at his own cost, by a citizen of the name of M. Tullius, unfortunately no connexion of the orator. This temple appears to have suffered very severely from the earthquake, and at present affords little evidence of its original architectural ornament; but we learn from existing remains that its walls were covered with slabs of marble, and that the columns of the portico were of the same valuable material.

All the temples above described, except that ascribed to Hercules, agree in being raised on an elevated *podium* or basement,—an arrangement usual with all similar buildings of Roman date. Neither their materials nor the style of their architecture exceed what might reasonably be expected in a second-rate provincial town; and the same may be said in general of the other public buildings. Among these the most conspicuous are the theatres, of which there were two, placed, as was usual in Greek towns, in close juxtaposition with one another. The largest of these, which was partly excavated in the side of the hill, was a building of considerable magnificence, being in great part cased with marble, and furnished with seats of the same material, which have, however, been almost wholly removed. Its internal construction and arrangements resemble those of the Roman theatres in general, though with some peculiarities that show Greek influence, and we learn from an inscription that it was erected in Roman times by two members of the same family, M. Holconius Rufus and M. Holconius Celer, both of whom held important municipal offices at Pompeii during the reign of Augustus. It appears, however, from a careful examination of the remains that their work was only a reconstruction of a more ancient edifice, the foundations of which, and some other portions, may be distinctly traced. The smaller theatre, which was erected, as we learn from an inscription, by two magistrates specially appointed for the purpose by the decurions of the city, was of older date than the large one, and appears to have been constructed about the same time as the amphitheatre, soon after the establishment of the Roman colony under Sulla. From the same source we learn that it was permanently covered—a rare thing with Roman theatres; but in the case of the larger theatre also the arrangements for the occasional extension of an awning (*velarium*) over the whole are distinctly found. The smaller theatre is computed to have been capable of containing fifteen hundred spectators, while the larger could accommodate five thousand persons.

Adjoining the theatres is a large rectangular enclosure, surrounded by a portico, the purpose of which has been the subject of considerable controversy, but it is now generally admitted to have been the quarters or barracks of the gladiators, who were permanently maintained in the city with a view to the shows in the amphitheatre. It is singular that it should have been at so considerable a distance from that building, which is situated at the south-eastern angle of the town, above 500 yards from the theatres. The amphitheatre was erected by the same two magistrates who built the smaller theatre, at a period when no permanent edifice of a similar kind had yet been

erected in Rome itself. But apart from its early date it has no special interest, and is wholly wanting in the external architectural decorations that give such grandeur of character to similar edifices in other instances. Being in great part excavated in the surface of the hill, instead of the seats being raised on arches, it is wanting also in the picturesque arched corridors which contribute so much to the effect of those other ruins. Nor are its dimensions (430 feet by 335) such as to place it in the first rank even of provincial structures of this class, though it may still strike a visitor of the present day as surprisingly large for a town of the population of Pompeii. But, as we learn from the case of their squabble with the people of Nuceria, the games celebrated in the amphitheatre on grand occasions would be visited by large numbers from the neighbouring towns.

Adjoining the amphitheatre was found a large open space, nearly square in form, which has been supposed to be a forum boarium or cattle market, but, no buildings of interest being discovered around it, the excavation was filled up again, and this part of the city has not been since examined.

Among the more important public buildings of Pompeii were the *thermæ*, or public baths, an institution that always held a prominent position in every Roman or Græco-Roman town. Three different establishments of this character have been discovered, of which the first, excavated in 1824, was for a long time the only one known. Though the smallest of the three, it is in some respects the most complete, and interesting; and it was until of late years the principal source from which we derived our knowledge of this important branch of the economy of Roman life. The vast series of edifices known by the name of *thermæ* at Rome, as well as those in other provincial towns, are in such a state of ruin as to throw little light upon the details of their arrangements. At Pompeii on the contrary the baths are so well preserved as to show at a glance the purpose of all the different parts—while they are among the most richly decorated of all the buildings in the city. We trace without difficulty all the separate apartments that are described to us by Roman authors—the *apodyterium*, *frigidarium*, *tepidarium*, *caldarium*, &c., together with the apparatus for supplying both water and heat, the places for depositing the bather's clothes, and other minor details which were for the first time revealed to us by the discovery of these interesting buildings. It is obviously impossible for us in this place to enter into a detailed description of these arrangements, for which we must refer our readers to the professed treatises on Roman antiquities, as well as to the larger works on Pompeii (see also *BATHS*, vol. iii. p. 435). The greater *thermæ*, which were not discovered till 1857, nor fully excavated till 1860, so that they are not described in the earlier works on the subject, are on a much more extensive scale than the others, and combine with the special purposes of the building a *palestra* and other apartments for exercise or recreation. The arrangements of the baths themselves are, however, almost similar to those of the lesser *thermæ*. In this case an inscription records the repair and restoration of the edifice after the earthquake of 63, but the period of its original construction is unknown. It appears, however, that these two establishments were found inadequate to supply the wants of the inhabitants, and a third edifice of the same character, but on a still more extensive scale, was in course of construction when the town was overwhelmed. The remains of this, which were first discovered and excavated in 1877, are, however, of comparatively little interest from the incomplete state in which the buildings were left.

Great as is the interest attached to the various public

buildings of Pompeii, and valuable as is the light that they have in some instances thrown upon similar edifices in other ruined cities, far more curious and interesting is the insight afforded us by the numerous private houses and shops into the ordinary life and habits of the population of an ancient town. In this respect Pompeii stands alone, among all antiquarian discoveries,—the difficulties of exploration at Herculaneum having greatly checked all further investigations on that equally promising site. But here again it is impossible in an article like the present to do more than briefly advert to the general results of the excavations (compare *ARCHITECTURE*, vol. ii. p. 420–21, and Pl. XVII.). The houses at Pompeii are generally low, rarely exceeding two stories in height, and it appears certain that the upper story was generally of a slight construction, and occupied by small rooms, serving as garrets, or sleeping places for slaves, and perhaps for the females of the family. From the mode of destruction of the city these upper floors were in most cases crushed in and destroyed, and hence it was long believed that the houses for the most part had but one story; but recent researches have in many cases brought to light incontestable evidence of the existence of an upper floor, and the frequent occurrence of a small staircase is in itself sufficient proof of the fact. The windows, as already mentioned, were generally small and insignificant, and contributed nothing to the external decoration or effect of the houses. In some cases they were undoubtedly closed with glass, but its use appears to have been by no means general. The principal living rooms, as well as those intended for the reception of guests or clients, were all on the ground floor, the centre being formed by the *atrium*, or hall, which was almost always open above to the air, and in the larger houses was generally surrounded with columns. Into this opened other rooms, the entrances to which seem to have been rarely protected by doors, and could only have been closed by curtains. All the apartments and arrangements described by Vitruvius and other ancient writers may be readily traced in the houses of Pompeii, and in many instances these have for the first time enabled us to understand the technical terms and details transmitted to us by Latin authors. We must not, however, hastily assume that the examples thus preserved to us by a singular accident are to be taken as representing the style of building in all the Roman and Italian towns. We know from Cicero that Capua was remarkable for its broad streets and wide-spread buildings, and it is probable that the Campanian towns in general partook of the same character. At Pompeii indeed the streets were not wide, but they were straight and regular, and the houses of the better class occupied considerable spaces, presenting in this respect no doubt a striking contrast, not only with those of Rome itself, but with those of many other Italian towns, where the buildings would necessarily be huddled together from the circumstances of their position. Even at Pompeii itself, on the west side of the city, where the ground slopes somewhat steeply towards the sea, houses are found which consisted of three stories or more.

The excavations systematically conducted for many years past have presented us with examples of houses of every description, from the humble dwelling-place of the artisan or proletarian, with only three or four small rooms, to the stately mansions of Sallust and Pansa,<sup>1</sup>—the last of which is the most regular as well as the most extensive of all,

<sup>1</sup> It may be observed that the names given in most cases to the houses are either arbitrary, or founded in the first instance upon erroneous inferences. Hence they are frequently changed, and great confusion arises in consequence in comparing the different works on the subject. A few only of the best known may be considered as established by long usage, among which are the two here referred to.

and may be taken as an almost perfect model of a complete Roman house of a superior class. But the general similarity in their plan and arrangement is very striking, and in all those that rise above a very humble class the leading divisions of the interior, the *atrium*, *tablinum*, *peristyle*, &c., may be traced with unfailing regularity. Another peculiarity that is found in all the more considerable houses in Pompeii is that of the front, where it faces one of the principal streets, being occupied with shops, usually of small size, and without any communication with the interior of the mansion. In a few instances indeed such a communication is found, but in these cases it is probable that the shop was used for the sale of articles grown upon the estate of the proprietor, such as wine, fruit, oil, &c., a practice that is still common in Italy. In general the shop had a very small apartment behind it, and probably in most cases a sleeping chamber above it, though of this the only remaining evidence is usually a portion of the staircase that led to this upper room. The front of the shop was open to the street, but was capable of being closed with wooden shutters, the remains of which have in a few instances been preserved. Of course it is only in a few cases that the particular purpose of the shop or trade of its owner can be determined, though, from the exceptional manner of their preservation, this can be done more frequently than might be expected. Thus not only have the shops of silversmiths been recognized by the precious objects of that metal found in them, but large quantities of fruits of various kinds preserved in glass vessels, various descriptions of corn and pulse, loaves of bread, moulds for pastry, fishing-nets, and many other objects, too numerous to mention, have been found in such a condition as to be identified without difficulty. Cooks' shops appear to have been numerous, as well as *thermopoliz*, where hot drinks were sold. Bakers' shops are also frequent, though arrangements for grinding and baking appear to have formed part of every large family establishment. In other cases, however, these were on a larger scale, provided with numerous querns or hand-mills of the well-known form, evidently intended for public supply. Another establishment on a large scale was a *fullonica* or fuller's shop, where all the details of the business were illustrated by paintings still visible on the walls. A dyer's shop, a tannery, and a shop where colours were ground and manufactured—an important business where almost all the rooms of every house were painted—are of special interest, as is also the house of a surgeon, where numerous surgical instruments were found, some of them of a very ingenious and elaborate description, but all made of bronze. Another curious discovery was that of the abode of a sculptor, containing his tools, as well as blocks of marble and half-finished statues. The number of utensils of various kinds found in the houses and shops is almost endless, and, as these are in most cases of bronze, they are generally in perfect preservation.

Of the numerous works of art discovered in the course of the excavations the statues and large works of sculpture, whether in marble or bronze, are inferior to those found at Herculaneum, but some of the bronze statuettes are of exquisite workmanship, while the profusion of ornamental works and objects in bronze and the elegance of their design, as well as the finished beauty of their execution, are such as to excite the utmost admiration,—more especially when it is considered that these are the casual results of the examination of a second-rate provincial town. The same impression is produced in a still higher degree by the paintings with which the walls of the private houses, as well as those of the temples and other public buildings, are adorned, and which are not merely of a decorative character, but in many instances present us

with elaborate compositions of figures, historical and mythological scenes, as well as representations of the ordinary life and manners of the people, which are full of interest to us, though often of inferior artistic execution. An illustration of the character of the Pompeian wall-paintings is given in the article *MURAL DECORATION*, vol. xvii. p. 42, fig. 8. Our knowledge of ancient painting is indeed derived to a much greater extent from Pompeii than from all other sources whatever; and, when we contemplate the variety and beauty of what we find here entombed, we cannot but ask ourselves what would have been the result had a great and opulent city like Capua or Neapolis been preserved to us in the same manner as the comparatively insignificant Pompeii. The same character of elaborate decoration, guided almost uniformly by good taste and artistic feeling, is displayed in the mosaic pavements, which in all but the humbler class of houses frequently form the ornament of their floors. One of these, well known as the battle of Alexander, presents us with the most striking specimen of artistic composition that has been preserved to us from antiquity (see *MOSAIC*, vol. xvi. p. 851, where part of this composition is shown in fig. 2).

The architecture of Pompeii must be regarded as presenting in general a transitional character from the pure Greek style to that of the Roman empire. The temples (as already observed) have always the Roman peculiarity of being raised on a *podium* of considerable elevation; and the same characteristic is found in most of the other public buildings. All the three orders of Greek architecture—the Doric, Ionic, and Corinthian—are found freely employed in the various edifices of the city, but rarely in strict accordance with the rules of art in their proportions and details; while the private houses naturally exhibit still more deviation and irregularity. In many of these indeed we find varieties in the ornamentation, and even in such leading features as the capitals of the columns, which remind one rather of the vagaries of mediæval architecture than of the strict rules of Vitruvius or the monotonous regularity of Greek edifices. One practice which is especially prevalent, so as to strike every casual visitor, is that of filling up the flutings of the columns for about one-third of their height with a thick coat of stucco, so as to give them the appearance of being smooth columns without flutings below, and only fluted above. The unpleasant effect of this anomalous arrangement is greatly aggravated by the lower part of each column being almost always coloured with red or yellow ochre, so as to render the contrast between the two portions still stronger. The architecture of Pompeii suffers also from the inferior quality of the materials generally employed. No good building stone was at hand; and the public as well as private edifices were constructed either of volcanic tuff, or brick, or the irregular masonry known to the Romans as *opus incertum*. Those which belong to the earlier or Oscan period of the city (before the establishment of the Roman colony) are for the most part of the former material, while those erected under the Roman empire, and especially those subsequent to the great earthquake of 63, are generally of slighter construction, and of a less durable character. In the private houses even the columns are mostly of brick, covered merely with a coat of stucco. In a few instances only do we find them making use of a kind of travertine, found in the valley of the Sarno, which, though inferior to the similar material so largely employed at Rome, was better adapted than the ordinary tuff for purposes where great solidity was required. The portion of the portico surrounding the forum which was in the process of rebuilding at the time when the city was destroyed was constructed of this material, while the earlier portions, as well as the principal temples that

adjoined it, were composed in the ordinary manner of volcanic tuff. Marble appears to have been scarce, and was sparingly employed. In some instances where it had been freely introduced, as in the great theatre, it would seem that the slabs must have been removed at a period subsequent to the entombment of the city.

Outside the gate leading to Herculaneum is found a house of a different character from all the others, which from its extent and arrangements was undoubtedly a suburban villa, belonging to a person of considerable fortune. It is called—as usual without any authority—the villa of Arrius Diomedes; but its remains are of peculiar interest to us, not only for comparison with the numerous ruins of similar buildings which occur elsewhere,—often of greater extent, but in a much less perfect state of preservation,—but as assisting us in understanding the description of ancient authors, such as Vitruvius and Pliny, of the numerous appurtenances frequently annexed to houses of this description. The remains of a still more extensive suburban house which were discovered in 1764, and to which the name was given, without the slightest foundation, of the villa of Cicero, are no longer visible, having been covered up again with earth (as was frequently done in the last century) after the works of art had been removed.

In the vaulted corridors of the first villa were discovered no less than seventeen skeletons of the unfortunate inhabitants, who had evidently fled thither for protection. Almost all the skeletons and remains of bodies found in the city were discovered in similar situations, in cellars or underground apartments,—those who had sought refuge in flight having apparently for the most part escaped from destruction, or having perished under circumstances where their bodies were easily recovered by the survivors. According to Dion Cassius, a large number of the inhabitants were assembled in the theatre at the time of the catastrophe, but no bodies have been found there, and they were probably sought for and removed shortly afterwards. Hence the whole number of such remains discovered is not so large as might at first be supposed. It cannot indeed be accurately estimated, the records of the excavations in the last century having been very imperfectly kept; but the total number as yet discovered can scarcely exceed three hundred. Of late years it has been found possible in many cases to take casts of the bodies found—a complete mould having been formed around them by the fine white ashes, partially consolidated by water.

The road leading from the gate of Herculaneum towards that city is bordered on both sides for a considerable extent by rows of tombs, as was the case with all the great roads leading into Rome, and indeed in all large Roman towns. Without of course approximating to the stately structures that adorned the Via Appia or Latina, these tombs are in many instances monuments of considerable pretension, and of a highly ornamental character, and naturally present in the highest degree the peculiar advantage common to all that remains of Pompeii, in their perfect preservation. Hardly any scene even in this extraordinary city is more striking than the *coup d'œil* of this long street of tombs, preserving uninjured the records of successive generations eighteen centuries ago. Unfortunately the names are all otherwise unknown; but we learn from the inscriptions that they are for the most part those of local magistrates and municipal dignitaries of Pompeii.

There appears to have been in the same quarter a considerable suburb, outside the gate, extending on each side of the road towards Herculaneum, apparently much resembling those which are now found throughout almost the whole distance from thence to Naples. It appears to have been known by the name of Pagus Augustus Felix.

No manuscripts have been discovered in Pompeii. Inscriptions have naturally been found in considerable numbers, and we are indebted to them for much information concerning the municipal arrangements of the town, as well as the construction of various edifices and other public works. The most interesting of these are such as are written in the Oscan dialect, which appears to have continued in official use down to the time when the Roman colony was introduced by Sulla. From that time the Latin language was certainly the only one officially employed, though Oscan may have still been spoken by a portion at least of the population. Still more curious, and almost peculiar to Pompeii, are the numerous writings scratched or rudely painted upon the walls, which have in some instances a semi-public character, such as recommendations of candidates for municipal offices, but more frequently are the mere expression of individual impulse and feeling, not uncommonly conveyed in rude and imperfect verses. In one house also a whole box was found filled with written tablets—diptychs and triptychs—containing the record of the accounts of a banker named L. Cæcilius Jucundus.

The inscriptions of a more formal character have been published by Mommsen, first in his *Inscriptiones Regni Neapolitani Latinae* (fol., Leipsie, 1852) and again in the tenth volume of the great *Corpus Inscriptionum Latinarum*, published at Berlin (1883). The fourth volume of the same work published in 1871 contains all the scratched and written inscriptions discovered up to that date, edited by Zangemeister (under the title *Inscriptiones Parietariae Pompeianae, Herculanenses, et Stabianae*); but the number has been since greatly increased, and a supplementary volume is in the press. The Oscan inscriptions, which are not comprised in the above collections, have been published by Fiorelli.

Most of the movable objects from Pompeii are now in the Museo Borbonico at Naples (see vol. xvii. p. 189).

Of the numerous works devoted to the antiquities and description of Pompeii generally it must suffice to mention a few. The earlier works, especially that of Mazois (*Les Ruines de Pompeii*, with its continuation by Gau, 4 vols. fol., Paris, 1812–38), and the two well-known works of Sir W. Gell (*Pompeiana*, 1st series, 2 vols. 8vo, London, 1824, 2d series, 1830), are still valuable for reference, though necessarily very imperfect. The popular treatise published by the Society for Useful Knowledge (*Pompeii*, 2 vols. 8vo, London, 1831) gives a good account of what had been then discovered, and the light thrown by it on ancient manners and customs. The more recent works of Breton (*Pompeii*, 8vo, Paris, 1855) and of Mr Dyer (*Pompeii: its History, Buildings, and Antiquities*, 8vo, London, 1867) bring down the record to a later period; and the successive editions of Overbeck's *Pompeii* (first published in 1856) have been kept continually on a par with the progress of discovery and research. The last edition of this valuable treatise (1884) is much the most complete and useful compendium of the whole subject that has yet appeared, and will supply all the wants of the ordinary reader. More special students will find there detailed references to the official records of the later discoveries that have been made under the direction of Signor Fiorelli, and to the numerous dissertations to which they have given rise. The great illustrated works of Zahn (Berlin, 1827–29) and Presuhn (fol., Leipsie, 1882) will furnish more elaborate representations of the decorative works with which almost all the buildings are adorned, while the student of ancient art may have recourse to the less ambitious collection of the ancient paintings by Helbig (*Wandgemälde der von Vesuv verschütteten Städte Campaniens*, Leipsie, 1868), with a supplementary volume published by Sogliano at Naples. A complete catalogue of all the works concerning Pompeii and Herculaneum will be found in a little book published at Milan in 1879 under the title of *Bibliotheca Pompeiana*. Unfortunately all works are rendered imperfect within a few years by the continued progress of the explorations and discoveries on the site. (E. H. B.)

POMPEY is the common English form of the Roman name Pompeius.

I. CNEIUS POMPEIUS MAGNUS (106–48 B.C.), the great triumvir, whose name we always associate with Caesar and Crassus, may be said to have led a soldier's life from his boyhood to his death. Born in 106 B.C., he fought

by his father's side when a stripling of seventeen in the Social or Italian War on the side of Sulla against the party of Marius and Cinna. Thus early in life he connected himself with the cause of the aristocracy, and a decisive victory which he won in 83 over the Marian armies gained for him from Sulla the title of "imperator." He followed up his successes in Italy by defeating the Marians in Sicily and Africa, and on his return to Rome in 81, though he was still merely an "eques" and not legally qualified to celebrate a triumph, he was allowed by general consent to enjoy this great distinction, while Sulla greeted him with the surname of Magnus, a title he always retained and handed down to his sons. Yet in 79 he used his influence in getting elected to the consulship a man politically opposed to Sulla, Æmilius Lepidus, who threatened Rome with another revolution and civil war in the interest of the democratic party. Pompey, however, at this crisis was loyal to his friends, and with the defeat of Lepidus the danger passed away. With some fears and misgivings the senate permitted him to retain the command of his victorious army, and decided on sending him to Spain, where, under a leader of singular ability, Sertorius, the Marian party was still formidable. Pompey was fighting in Spain from 76 to 71, and though at first he met with serious reverses he was ultimately successful, his great opponent, Sertorius, having, it would seem, lost the confidence of some of the native Spanish tribes. In 71 he was again in Italy at the head of his army, and won fresh glory by giving a finishing blow to the slave insurrection of Spartacus. That same year, amid great popular enthusiasm, but without the hearty concurrence of the senate, whom he had alarmed by talking of restoring the dreaded power of the tribunes, and though still merely an "eques," he was elected with Crassus to the consulship, and entered Rome in triumph for his Spanish victories. The following year saw the work of Sulla undone: the tribuneship was restored, and the administration of justice was no longer left exclusively to the senate, but was to be shared by them with the wealthier portion of the middle class, the "knights," as from old time they had been called, and the farmers and collectors of the revenue. The change was really necessary, as the provincials could never get justice from a court composed of senators, and it was carried into effect by Pompey with Cæsar's aid. Pompey as a matter of course rose still higher in popularity, and on the motion of the tribune Gabinius in 67 he was entrusted with an extraordinary command over the greater part of the empire, specially for the extermination of piracy in the Mediterranean, by which the corn supplies of Rome were seriously endangered, while high prices of provisions caused great distress. It soon appeared that the right man had been chosen for the work: the price of corn fell immediately on Pompey's appointment, and in forty days the Mediterranean was swept from end to end and the pirates cleared out of its waters. Next year, on the proposal of the tribune Manilius, he had a yet further extension of his powers, the whole of Rome's empire in the East being put under his control for three years with the view of finally terminating the war with Mithradates, king of Pontus, who had recovered from the defeats he had sustained from Lucullus and regained his dominions. Both Cæsar and Cicero supported the tribune's proposal, which was easily carried in spite of the interested opposition of the senate and the aristocracy, several of whom held provinces which would now be practically under Pompey's command. Pompey was now by far the first man in the Roman world. His operations in the East were thoroughly successful, and, though no doubt he owed something to the victories of Lucullus, he showed himself an able soldier. The wild tribes of the Caucasus were cowed by the

Roman arms, and the king of Pontus himself fled from Asia across the Black Sea to Panticapæum, the modern Kertch. In the years 64 and 63 Syria and Palestine were annexed to Rome's empire. After the capture of Jerusalem Pompey is said to have entered the temple, and even the Holy of Holies. Asia and the East generally were left under the subjection of petty kings who were mere vassals of Rome. Several cities had been founded which became centres of Greek life and civilization. A really great work had been accomplished, and Pompey, now in his forty-fifth year, returned to Italy in 61 to celebrate the most magnificent triumph which Rome had ever witnessed, and to be hailed as the conqueror of Spain, Africa, and Asia.

The remainder of Pompey's life is inextricably interwoven with that of Cæsar. He was married to Cæsar's daughter Julia, and as yet the relations between the two had been friendly. On more than one occasion Cæsar had supported Pompey's policy, which of late had been in a decidedly democratic direction. Pompey was now in fact ruler of the greater part of the empire, while Cæsar had only the two provinces of Gaul. The control of the capital, the supreme command of the army in Italy and of the Mediterranean fleet, the governorship of the two Spains, the superintendence of the corn supplies, which were mainly drawn from Sicily and Africa, and on which the vast population of Rome was wholly dependent, were entirely in the hands of Pompey. The senate and the aristocracy disliked and distrusted him, but they felt that, should things come to the worst, they might still find in him a champion of their cause. At the same time the senate itself was far from unanimous: among many of its members there was a feeling that a military imperialism had become a necessity, while to the rich and idle world generally peace and quiet at any price seemed the best of all blessings. Hence the joint rule of Pompey and Cæsar was not unwillingly accepted, and anything like a rupture between the two was greatly dreaded as the sure beginning of anarchy throughout the Roman world. With the death of Pompey's wife Julia, in 54, came strained relations between him and Cæsar, and soon afterwards he drew closer to what we may call the old conservative party in the senate and aristocracy. The end was now near, and Pompey blundered into a false political position and an open quarrel with Cæsar. In 50 the senate by a very large majority revoked the extraordinary powers conceded to Pompey and Cæsar in Spain and Gaul respectively. Pompey's refusal to submit gave Cæsar a good pretext for declaring war and marching at the head of his army into Italy. At the beginning of the contest, the advantages were decidedly on the side of Pompey, but very speedily the superior political tact of his rival, combined with extraordinary promptitude and decision in following up his blows, turned the scale against him. Pompey's cause, with that of the senate and aristocracy, was finally ruined by his defeat in 48 in the neighbourhood of the Thessalian city Pharsalus. That same year he fled with the hope of finding a safe refuge in Egypt, but was treacherously murdered as he was stepping on the shore by one of his old centurions. He had just completed his fifty-eighth year.

Pompey, though he had some great and good qualities, hardly deserved his surname of "the Great." He was certainly a very good soldier, and is said to have excelled in all athletic exercises, but he fell short of being a first-rate general. He won great successes in Spain and more especially in the East, but for these he was no doubt partly indebted to what others had already done. Of the gifts which make a good statesman he had really none. As plainly appeared in the last years of his life, he was too weak and irresolute to choose a side and stand by it. Pitted against such a man as Cæsar, he could not but fail. But to his credit be it said that in a corrupt time he never used his opportunities for plunder and extortion, and his domestic life was pure and simple. A very complete life of Pompey will be found in Smith's *Dict. of Greek and Roman Biography*. The allusions to him in Cicero's works are very frequent.

II. **SEXTUS POMPEIUS MAGNUS** (75–35 B.C.), the younger son of Pompey the Great, born 75 B.C., continued after his father's death to prolong the struggle against the new rulers of the Roman empire. Caesar's victory at Munda in 45 drove him out of Corduba (Cordova), though for a time he held his ground in the south of Spain, and defeated Asinius Pollio, the governor of the province. In 43, the year of the triumvirate of Octavius, Antony, and Lepidus, he was proscribed along with the murderers of Caesar, and not daring to show himself in Italy he put himself at the head of a fleet manned chiefly by slaves or proscribed persons, by means of which he made himself master of Sicily, and from thence ravaged the coasts of Italy. Rome was threatened with a famine, as the corn supplies from Egypt and Africa were cut off by his ships, and it was thought prudent to negotiate a peace with him, which was to leave him in possession of Sicily, Sardinia, and Achaia, provided he would allow Italy to be freely supplied with corn. But the arrangement could not be carried into effect, as Sextus renewed the war and gained some considerable successes at sea. However, in 36 his fleet was defeated and destroyed by Agrippa off the north coast of Sicily, and in the following year he was murdered at Mitylene by an officer of Antony. He had his father's bravery as a soldier, but seems to have been a rough uncultivated man. (W. J. B.)

**PONCE DE LEON, LUIS.** See **LEON, LUIS PONCE DE.**

**PONCELET, JEAN VICTOR** (1788–1867), mathematician, was born at Metz, July 1, 1788. From 1808 to 1810 he attended the Polytechnic School, and afterwards, till 1812, the Practical School at Metz. He then became lieutenant of engineers, and took part in the Russian campaign, during which he was taken prisoner and was confined at Saratoff on the Volga. It was during his imprisonment here that, "privé de toute espèce de livres et de secours, surtout distrait par les malheurs de ma patrie et les miens propres," as he himself puts it, he began his researches on projective geometry which led to his great treatise on that subject. This work, the *Traité des Propriétés Projectives des Figures*, which was published in 1822 (2d ed., 1865), is occupied with the investigation of the projective properties of figures, that is, such properties as are not altered by projection. In his investigation he employs the ideas of continuity, of homologous figures, and of reciprocal polars; and by means of these, without any analysis, he was able to establish all the known properties of lines and surfaces of the second degree, and to discover others unknown before. This work entitles Poncelet to rank as one of the greatest of those who took part in the development of the modern geometry of which Monge was the founder. From 1815 to 1825 he was occupied with military engineering at Metz; and from 1825 to 1835 he was professor of mechanics at the Practical School there. In 1826, in his *Mémoire sur les Roues Hydrauliques à Aubes Courbes*, he brought forward improvements in the construction of water-wheels, which more than doubled their efficiency. In 1834 he became a member of the Academy; from 1838 to 1848 he was professor to the faculty of sciences at Paris, and from 1848 to 1850 commandant of the Polytechnic School, where he effected a reform in the course of study. At the London International Exhibition in 1851 he had charge of the department of machinery, and wrote a report on the machinery and tools on view at that exhibition. He died December 22, 1867. Besides those referred to above, he wrote a number of works, and contributed many papers to *Crelle's Journal*, &c., on different branches of engineering and mathematics.

**POND, JOHN** (c. 1767–1836), astronomer-royal, was born about 1767 in London, where his father made a fortune in trade. He entered Trinity College, Cambridge, at the

age of sixteen, but took no degree, his course being interrupted by severe pulmonary attacks which compelled a prolonged residence abroad. His travels extended from Lisbon to Constantinople and the Nile, and were turned to account for astronomical observation. In 1800 he settled at Westbury near Bristol, and began to determine star-places with a fine altitude and azimuth circle of 2½ feet diameter by Troughton. His demonstration in 1806 (*Phil. Trans.*, xcvi. 420) of a change of form in the Greenwich mural quadrant led to the introduction of astronomical circles at the Royal Observatory, and to his own appointment as its head. Elected a fellow of the Royal Society, February 26, 1807, he married and went to live in London in the same year, and in 1811 succeeded Maskelyne as astronomer-royal.

During an administration of nearly twenty-five years, Pond effected a reform of practical astronomy in England comparable to that effected by Bessel in Germany. In 1821 he began to employ the method of observation by reflexion; and in 1825 he devised means (see *Mem. R. A. Soc.*, ii. 499) of combining two mural circles in the determination of the place of a single object, the one serving for direct and the other for reflected vision. (By an invention of Airy's, the same object is now attained with one instrument.) During Pond's term of office the instrumental equipment at Greenwich was completely changed, and the number of assistants increased from one to six. The superior accuracy of his determinations was due in part to his systematic attention to the errors of his instruments, in part to his plan of multiplying observations. During a prolonged controversy (1810–24), he consistently denied the reality of Brinkley's imaginary star-parallaxes (see his papers in *Phil. Trans.*, cviii. 477; cxiii. 53). Delicacy of health impeded his activity, and compelled his retirement in the autumn of 1835. He died at Blackheath, September 7, 1836, and was buried beside Halley in the churchyard of Lee. The Copley medal was conferred upon him in 1823, and the Lalande prize in 1817 by the Paris Academy, of which he was a corresponding member. He published eight folio volumes of *Greenwich Observations*, translated Laplace's *Système du Monde* (in 2 vols. 8vo., 1809), and contributed thirty-one papers to scientific collections. His catalogue of 1112 stars (1833) was of great value.

See *Mem. R. A. Soc.*, x. 357; *Annual Biography and Obituary*, 1837; Grant, *Hist. of Phys. Astr.*, p. 491; Royal Society's *Cat. of Sc. Papers*.

**PONDICHERRI**, chief settlement of the French possessions in the East Indies, situated on the Coromandel coast, in 11° 56' N. lat. and 79° 53' E. long.; it is 86 miles south of Madras, and is connected with the South Indian Railway system. The territory consists of three districts—Pondicherry, Villianur, and Bahur—comprising an area of 112 square miles, with a population in 1881 of 139,210. The town is divided into a European and a native quarter, separated from one another by a canal. The French first settled at Pondicherry in 1674; it was besieged four times by the British, the last time in 1793; but it was finally restored in 1816. On the whole the town is considered very salubrious; the purity of its water-supply is said to be unrivalled in any other town in southern India.

**PONEVYEZH**, a district town of Russia, in the government of Kovno, situated on the upper course of the Nevyeja river, and connected by rail with Libau on the north-west and with Dünauburg (80 miles distant) on the east. It is an old town which was almost totally destroyed by the pestilence of 1550, but was rebuilt and repeopled owing to its advantageous situation on the highway to the Baltic. After having suffered severely from wars in the 17th and 18th centuries it was annexed to Russia on the

third dismemberment of Poland, but had neither manufacturing nor commercial importance until it was brought into railway connection with Libau, with which seaport it now carries on some trade in agricultural produce. Its population (8070 in 1865) had in 1881 reached 15,030, of whom nearly one-half were Jews.

PONIATOWSKI, a family of Poland, the earliest member of which to acquire high distinction was STANISLAUS CIOLEK (1677–1762), regarding whose descent there are conflicting accounts,—some tracing it to the Lombard Counts Torelli, one of whom in the seventeenth century married a daughter of Albert of Poniatow, and added the name of Poniatowski to his own, which he changed to its equivalent in Polish, Ciolek, while others affirm that the name Poniatowski was adopted by one of two brothers from an estate which fell to his share, while it is also asserted that Stanislaus Ciolek was the natural son of Prince Sapicha, and was adopted by a Polish nobleman named Poniatowski (see Szymanowski, *Die Poniatowski*, Geneva, 1880). In any case he had sufficient influence and ability to insure his rapid promotion in the army of Charles XII., and as major-general at the battle of Poltava in 1709 was able by his self-command in facilitating the passage of the Dniéper to save the retreating army. In 1711 he was sent on a special embassy to Constantinople, when he succeeded in obtaining from the sultan a promise to send an army to aid Charles in the war with Russia; but on account of a change in the office of grand vizier the promise was never carried out. All possibility of undertaking a Russian invasion being therefore at an end, he was appointed by Charles governor of the duchy of Zweibrücken. After the death of Charles, he gave his adhesion to Augustus II., by whom he was in 1724 made grand treasurer of Lithuania, and in 1731 palatine of Mazovia. On the death of Augustus II. he sought to effect the promotion of Stanislaus Leszczyński to the throne, but ultimately he gave in his submission to Augustus III., and after holding under him several high offices was in 1752 appointed castellan of Cracow. He was the author of *Remarques d'un Seigneur Polonais sur l'Histoire de Charles XII. par Voltaire*, 1741, which was translated into English in the same year. He died in 1762, leaving by his marriage with Constance Princess Czartoryski four sons, the best known of whom was the second, STANISLAUS AUGUSTUS (1732–1798), king of Poland, born 17th January 1732. Sent by Augustus III. to the court of Russia, he won the favour of the grand-duchess Catherine, who succeeded to the throne by the assassination of her husband, 9th July 1762. Through her influence he was, 7th September 1764, chosen king of Poland. For an account of his despicable and disastrous rule see POLAND (pp. 297–8). After signing his abdication, 25th November 1795, he took up his residence at St Petersburg, where he enjoyed a pension of 200,000 ducats paid jointly by Austria, Russia, and Prussia. He died unmarried, 12th February 1798 (see *Mémoires Secrets inédits de Stanislas II. Auguste*, Leipsic, 1867, and De Mouy, *Correspondance inédite de Roi Stanislas-Auguste et de Madame Geoffrin*, Paris, 1875). Of the other sons of Stanislaus Poniatowski, Casimir (1721–1800), the eldest, was grand chamberlain of Poland and commander of the royal guard; Andrew (1735–1773) became an Austrian field marshal; and Michael (1736–1794) was ultimately promoted primate of Poland. JOSEPH ANTON (1762–1813), prince and marshal of France, son of Andrew Poniatowski was born at Warsaw, 7th May 1762. At the age of sixteen he entered the service of Austria. After the resolution of the diet to reorganize the Polish army he was recalled and obtained the rank of major-general. On the outbreak of hostilities with Russia in 1792 he was made com-

mander of the army defending central Poland. When the king his uncle acceded to the confederation of Targovitz he resigned his commission, but on the outbreak of the insurrection in 1794 he enrolled himself as a volunteer under Kosciuszko, although Kosciuszko had previously held inferior military rank to his own. In command of a division he had charge of the defence of the northern side of Warsaw, and after its capitulation he went to Vienna. In 1798 he returned to Warsaw, having obtained from the Prussians a portion of his confiscated estates. On the arrival of Napoleon at Warsaw, 19th December 1806, Poniatowski accepted his invitation to become general of a national Polish army, which, fired by the hope of national independence, gathered to the number of 27,000, to assist Napoleon in his Russian campaign. After the peace of Tilsit, 7th July 1807, the duchy of Warsaw was created, and Poniatowski became minister of war. On the invasion of the duchy in 1809 he fought a desperate battle near the village of Raszyn, and, being permitted afterwards to retreat across the Vistula, invaded Galicia and compelled the Russians to evacuate Cracow. In Napoleon's campaigns he held the command of the Polish army corps, distinguishing himself at Smolensk, Borodino, and Leipsic, where he took 1000 prisoners, and in token of his brilliant exploit was created by Napoleon a marshal of France the same evening. He was employed in covering the retreat from Leipsic, and while charging a column of Prussian infantry was wounded by a ball in the shoulder. When the enemy obtained possession of the suburbs he endeavoured to join the main army by plunging into the Elster, but was fired upon and, enfeebled by wounds, was drowned, 19th October 1813. JOSEPH (1816–1873), grandson of Casimir mentioned above, was born 4th February 1816, at Rome. Entering the Tuscan service, he went in 1849 as minister of Tuscany to London. In 1850 he took up his residence in Paris, and becoming a naturalized citizen was in 1854 chosen a member of the French senate. In 1870 he removed to London, where he supported himself by teaching music. He was the composer of several operas. He died 3rd July 1873.

PONS, JEAN LOUIS (1761–1831), French astronomer, born at Peyre (Haut-Dauphiné), 24th December 1761, received a place at the Marseilles observatory in 1789, and in 1819 became the director of the new observatory at Marlia near Lucca, which he left in 1825 for the observatory of the museum at Florence. Here he died October 14, 1831. Pons was famous as a comet-hunter, discovering between 1801 and 1827 thirty-seven of these bodies, one of which (discovered 26th November 1818) is the famous comet named after Encke, who determined its orbit.

PONSARD, FRANÇOIS (1814–1867), French dramatist, was born at Vienne in Dauphiné on the 1st June 1814. He was bred a lawyer, and his first performance in literature was a translation of *Manfred* (1837). But the first important, and indeed the most important, event of his life was the representation of his play *Lucrèce* at the Théâtre Français on the 1st April 1843. This date is a kind of epoch in literary and dramatic history, because it has been supposed to mark a reaction against the romantic style of Dumas and Hugo. In reality, however, Ponsard was only a romantic of a somewhat tamer genius than those who had gone before him. It so happened that the tastes and capacities of the most popular actress of the day, Rachel, suited his style of drama, and this contributed greatly to his own popularity. He followed up *Lucrèce* with *Agnès de Méranie* (1846), *Charlotte Corday* (1850), and others. Ponsard accepted the empire, though with no very great enthusiasm, and received the post of librarian to the senate, which, however, he soon resigned, fighting a blood-

less duel with a journalist on the subject. *L'Honneur et l'Argent*, one of his most successful plays, was acted in 1853, and he became an Academician in 1855. For some years he did little, but in 1866 he obtained great success with *Le Lion Amoureux*. He died a year later, at Paris in July 1867, soon after his nomination to the commandership of the Legion of Honour. His widow was pensioned. Ponsard is no doubt in some ways a remarkable dramatist. Unlike most men who have achieved considerable success on the stage, he did not overwrite himself, and most of his plays hold a certain steady level of literary and dramatic ability. But, as has been said, his popularity is in the main due to the fact that he found an actress ready to hand for his pieces, and that his appearance coincided with a certain public weariness of the grander but also more extravagant and unequal style of 1830.

PONTANUS, JOVIANUS (1426-1503), a famous Italian humanist and poet, was born in 1426 at Cerreto in the duchy of Spoleto, where his father was murdered in one of the frequent civil brawls which then disturbed the peace of Italian towns. His mother escaped with the boy to Perugia, and it was here that Pontano received his first instruction in languages and literature. Failing to recover his patrimony, he abandoned Umbria, and at the age of twenty-two established himself at Naples, which continued to be his chief place of residence during a long and prosperous career. He here began a close friendship with the distinguished scholar, Antonio Beccadelli, through whose influence he gained admission to the royal chancery of Alphonso the Magnanimous. Alphonso discerned the singular gifts of the young scholar, and made him tutor to his sons. Pontano's connexion with the Aragonese dynasty as political adviser, military secretary, and chancellor was henceforth a close one; and the most doubtful passage in his diplomatic career is when he welcomed Charles VIII. of France upon the entry of that king into Naples in 1495, thus showing that he was too ready to abandon the princes upon whose generosity his fortunes had been raised. Pontano illustrates in a marked manner the position of power to which men of letters and learning had arrived in Italy. He entered Naples as a penniless scholar. He was almost immediately made the companion and trusted friend of its sovereign, loaded with honours, lodged in a fine house, enrolled among the nobles of the realm, enriched, and placed at the very height of social importance. Following the example of Pomponio Leto in Rome and of Cosimo de' Medici at Florence, Pontano founded an academy for the meetings of learned and distinguished men. This became the centre of fashion as well as of erudition in the southern capital, and subsisted long after its founder's death. In 1461 he married his first wife, Adriana Sassone, who bore him one son and three daughters before her death in 1491. Nothing distinguished Pontano more than the strength of his domestic feeling. He was passionately attached to his wife and children; and, while his friend Beccadelli signed the licentious verses of *Hermaphroditus*, his own Muse celebrated in liberal but loyal strains the pleasures of conjugal affection, the charm of infancy, and the sorrows of a husband and a father in the loss of those he loved. Not long after the death of his first wife Pontano took in second marriage a beautiful girl of Ferrara, who is only known to us under the name of Stella. Although he was at least sixty-five years of age at this period, his poetic faculty displayed itself with more than usual warmth and lustre in the glowing series of elegies, styled *Eridanus*, which he poured forth to commemorate the rapture of this union. Stella's first child, Lucilio, survived his birth but her long remain to comfort the days; Stella's second child, Lucilio, survived his birth but had already lost his only son

by the first marriage; therefore his declining years were solitary. He died in 1503 at Naples, where a remarkable group of terra-cotta figures, life-sized and painted, still adorns his tomb in the church of Monte Oliveto. He is there represented together with his patron Alphonso and his friend Sannazzaro in adoration before the dead Christ.

As a diplomatist and state official Pontano played a part of some importance in the affairs of southern Italy and in the Barons' War, the wars with Rome, and the expulsion and restoration of the Aragonese dynasty. But his chief claim upon the attention of posterity is as a scholar. His writings divide themselves into dissertations upon such topics as the "Liberalty of Princes" or "Feroeity," composed in the rhetorical style of the day, and poems. He was distinguished for energy of Latin style, for vigorous intellectual powers, and for the faculty, rare among his contemporaries, of expressing the facts of modern life, the actualities of personal emotion, in language sufficiently classical yet always characteristic of the man. His prose treatises are more useful to students of manners than the similar lucubrations of Poggio. Yet it was principally as a Latin poet that he exhibited his full strength. An ambitious didactic composition in hexameters, entitled *Urania*, embodying the astronomical science of the age, and adorning this high theme with brilliant mythological episodes, won the admiration of Italy. It still remains a monument of fertile invention, exuberant facility, and energetic handling of material. Not less excellent is the didactic poem on orange-trees, *De Hortis Hesperidum*. His most original compositions in verse, however, are elegiac and hendecasyllabic pieces on personal topics—the *De Conjugali Amore*, *Eridanus*, *Tumuli*, *Nenia*, *Baiæ*, &c.—in which he uttered his vehemently passionate emotions with a warmth of southern colouring, an evident sincerity, and a truth of painting from reality which make the reader pardon an erotic freedom that is alien to our present taste. These lyrical compositions breathe the atmosphere of Naples, reproduce its scenery with wonderful brilliancy, and introduce us to the customs of its pleasure-loving pagan people. Yet, in spite of their excessive voluptuousness, we rise from their perusal convinced that their author was essentially a good man, a loving husband and father, and an attached friend.

Pontano's prose and poems were printed by the Aldi at Venice. For his life see Ardito, *Giovanni Pontano e i suoi Tempi*, Naples, 1871; for his place in the history of literature, Symonds, *Renaissance in Italy*. (J. A. S.)

PONTECORVO, a city of Italy in the province of Caserta, on the left bank of the Garigliano, with a population of 5172 in 1881 (commune 10,191), answers to the ancient Fregellæ, a Volscian city, colonized in 323 B.C. by the Romans, who thus occasioned the Second Samnite War. The principality of Pontecorvo (about 40 square miles in extent), which Napoleon bestowed on Bernadotte in 1806, was in 1810 incorporated with the French empire.

PONTEFRAC, or POMFRET, a market town and municipal and parliamentary borough in the West Riding of Yorkshire, England, finely situated on an eminence near the junction of the Calder and Aire, and on three railway lines, 13 miles south-east of Leeds, and 14 north-west of Doncaster. The streets are wide and regular, and there are many good houses and shops. A park over 300 acres in extent is used as a public recreation ground. The most important of the antiquarian remains are the ruins of the famous castle situated on a rocky height, originally covering with its precincts an area of over 8 acres, and containing in all eight round towers. The principal feature remaining is the keep. The castle is said to occupy the site of a fortress erected by Ailric, a Saxon thane. It was founded by Ilbert de Lacy shortly after the Conquest, and probably nearly completed by Ilbert de Lacy the second, who died about 1141. From that time till its demolition in 1649 it was the great stronghold of South Yorkshire. It was the cradle of the dukes of Lancaster, and in it Richard II. was, after his deposition, "kept secretly" till his death. Many persons of rank and influence have been confined in it as political prisoners. During the wars of York and Lancaster it was a centre of intrigue and conspiracy. In 1536 it surrendered to Aske, the leader of the "pilgrimage of grace." At the beginning of the Civil War it was garrisoned for Charles, and it underwent four sieges, three of them by the Parliamentary

forces, and one by the Royalists. After its capitulation to Lambert in March 1649 it was dismantled. Below the castle is All Saints church, which suffered severely during the siege of the castle, but still retains some work of the 12th century. In 1837 the tower and transepts were fitted up for divine service. The church of St Giles, formerly a chapel of ease to All Saints, but made parochial in the 18th century, is of Norman date, but most of the present structure is modern. The 17th century spire was removed in 1707, and replaced by a square tower, which was rebuilt in 1797; the chancel was rebuilt in 1869. In Southgate is an ancient hermitage and oratory cut out of the solid rock, which dates from 1396. On St Thomas's Hill, where Thomas, earl of Lancaster, was beheaded in 1322, a chantry was erected in 1373, the site of which is now occupied by a windmill built of its stones. At Monkhill there are the remains of a Tudor building called the Old Hall, probably constructed out of the old priory of St John's. A grammar school of ancient foundation, renewed by Queen Elizabeth and by George III., is now in abeyance. The town hall was built in 1796 on the site of one erected in 1655, which succeeded the old moot-hall, dating from Saxon times. Among other buildings are the court-house, the market hall, the assembly room (a handsome building adjoining the town-hall), and the dispensary. The principal almshouse, that of St Nicholas, dates from Saxon times. Trinity Hospital was founded in the 14th century by the celebrated Sir Robert Knolles. There are extensive gardens and nurseries in the neighbourhood, and hickories are largely grown for the manufacture of the celebrated Pontefract cakes. The town possesses iron foundries, clock and watch manufacturing, tanneries, hatteries, corn mill, and brick and terra-cotta works. The population of the municipal borough (extended in 1875) in 1871 was 6432, and in 1881 it was 8798, the population of the parliamentary borough (area 7315 acres) in the same years being 11,565 and 15,322. The increase is mainly due to the fact that Pontefract is now a military centre.

There are indications that the Romans were stationed near the present town, which is lying the Bridge Street. In Domesday it is called Terebith, and is said to have been held by the king (9th and 10th centuries). It then possessed a church and priest, an abbey, and three mills. Subsequently it is mentioned as Kirkby. Of the cause of the change of the name to Pontefract various conjectures are given. According to one account it was because when William I. passed to the conquest of the north his power was delayed by a broken bridge. But this was at Ferrybridge, 2 miles off; according to another the name was borrowed from its Norman possessor, the Count of Pontefract in Normandy (which, however, never existed); and according to a third the name perpetuates the remarkable preservation from drowning of those who fell into the river when the concourse of people made the bridge give way on the arrival of St William of Canterbury in 1153 (although all contemporary historians call the place Pontefract when Archbishop Thurstan died there in 1140). The town received a charter from Roger de Ley in 1194, and was incorporated in the time of Richard III. As early as 1297 it returned two members to parliament; but there was a long discontinuance in the 14th, 15th, and 16th centuries. The practice was revived under James I. The "redistribution" measure of 1855 deprives it of one of its members. The municipal borough is divided into three wards, and is governed by six aldermen and eighteen councillors.

PONTEVEDRA, a maritime province of Spain, is bounded on the N. by Coruña, on the E. by Lugo and Orense, on the S. by Portugal (Entre Douro e Minho), and on the W. by the Atlantic, and has an area of 1739 square miles. The general character of the province is hilly, with a deeply indented coast; its products are those common to all GALICIA (q.v.), of which historical province it formed a part. The population in 1877 was 451,916, the municipalities with a population over 10,000 being La Estrada (23,528), Lalín (16,217), Lavadores (13,658). PONTEVEDRA (noticed below), Puenteareas (14,566), Redondela (10,073), Silleda (13,346), Tomiño (11,150), Tuy

(11,710), and Vigo (13,416). Vigo is connected by rail with Tuy and Orense, and the line from Santiago to Vigo is open as far as to Carril.

PONTEVEDRA, capital of the above province, and an episcopal see, is a picturesque old granite-built town, pleasantly situated at the head of the Ría de Pontevedra, where the Lerez is spanned by the old Roman bridge (whence the name—*pons vetus*). The inhabitants engage in agriculture, sardine fishing, and the manufacture of cloth and hats. The population of the municipality in 1877 was 19,857.

PONTIANAK. See Borneo.

PONTIFEX. The principal college of priests in ancient Rome consisted of the *pontifices*, the *rex sacrorum*, and the *flamines*, under the headship of the *pontifex maximus*. The *rex sacrorum* was the functionary who under the republic succeeded to the sacrificial duties which in old time had been performed by the king; the *flamines* were sacrificial priests of particular gods, the most important being the *pater Dialis*, or priest of Jupiter, whose wife, the *flaminia Dialis*, was priestess of Juno. The *pontifices* on the other hand were not assigned to the service of particular gods, but performed general functions of the state religion; and their head, the *pontifex maximus*, was the highest religious authority in the state. For, while the *rex sacrorum* succeeded to the liturgical functions of the king, it was the *pontifex maximus* who inherited the substance of power in sacred things; the other members of the college were his counsellors and helpers, but no more. It is probable that there was no supreme pontifex under the kings, but that in accordance with the general rule that several officers went in threes, following the number of the old tribes, the king sat as sixth and chief among the five pontifices whom Numa is said to have instituted. The functions of *pontifex maximus* were indeed too weighty to be discharged by a subject in a monarchical government, and from Augustus to Gratian (382 A.D.) this supreme priesthood was held by the emperors in person. The original idea of the pontificate is as obscure as the name; it is by no means certain that *pontifex* means bridge-maker (as the commonest etymology has it) with reference to the duty of maintenance of the sacred Sublidian bridge, for there were *pontifices* from of old in other parts of Italy. Marquardt conjectures that the name originally denoted atoning functions, from the same root as appears in *ponere*, *pono*. In historical times the *pontifices* had a very extended sphere of duties, and claimed to possess professional "knowledge of things human and divine." The supreme pontiff was in the religion of the state what the father was in the religion of the family. His dwelling was in the *regia* close to the altar of Vesta, the sacred hearth of the state; and the most sacred objects of national worship, the *penates publici* and the mysterious palladia of Roman sovereignty, were his special care. The *flamines* and vestal virgins were appointed by him and stood under his paternal power, and the stated service of their cults, as well as those exercises of public religion for which no special priests were provided, were under his charge or that of the college in which he presided. The pontiffs, moreover, supplied technical guidance and help in those religious functions in which the senate or magistrates had the first part; while the charge of the calendar with its complicated intercalation and system of feast days gave them an important influence on affairs of civil life. The control of the calendar is closely connected with the duties pertaining to the pontifical archives, which, besides a mass of ritual directions and the like, embraced the calendars of past years (including the *fasti consulares*) and the *Annales maximus* or annual chronicle of public events. Further the pontiffs had the weighty function of

declaring and interpreting the laws of religion, which involved such important social matters as marriage and testamentary dispositions; but this function was declaratory and not magisterial; the state gave no executive power to the pontiffs, save only that the *pontifex maximus* exercised disciplinary authority over those priestly persons who stood under his paternal power. The pontiffs, who held office for life, originally filled up the vacancies in their number by cooptation, but as early as 212 B.C. the head of their college was named by the voice of the people, and in 104 B.C. the choice of the members of the priestly colleges was also transferred to *comitia* of a peculiar constitution. The number of *pontifices* was gradually enlarged, first to nine and then, under Sulla, to fifteen, and the emperors exercised the right of adding supernumeraries at will.

**PONTINE MARSHES.** See *LATVIUM*, vol. xiv. p. 343.

**PONTOISE**, a commercial town of France, at the head of an arrondissement of the department Seine-et-Oise, 18 miles by rail north-west of Paris, picturesquely situated on the right bank of the Oise where it is joined by the Viosne, and at the intersection of the railway from Paris to Dieppe by Gisors with that of the valley of the Oise. The traffic on the main river is large, and the tributary drives numerous mills. Of the many convents and churches that used to exist in the town two only remain: St Maclou, a church of the 12th century, was altered and restored in the 15th and 16th centuries by Pierre Lemercier, the famous architect of St Eustache at Paris; and Notre Dame, of the close of the 16th century, contains the tomb of St Gautier (13th century). Grain and flour are the principal staples of the trade of Pontoise; the population in 1881 was 6675.

Pontoise existed in the time of the Gauls as Briva Isaræ (i.e., Bridge of the Oise). The Romans made it the seat of forges dedicated to Vulcan, and thus the district came to be distinguished as Pagus Vulcanius or the Vexin. Pontoise was destroyed by the Normans in the 9th century, united with Normandy in 1032, and acquired by Philip I. in 1064. Lying on the borders of the two states it often passed from one to the other. The English took it in 1419, and again in 1436. In 1441 Charles VII. took it by storm after a three months' siege. After belonging to the count of Charolais down to the treaty of Conflans, it was given as a dowry to Jeanne of France when she was divorced by Louis XII. The parlement of Paris several times met in the town; and in 1561 the states-general convoked at Orleans removed thither after the death of Francis II. During the Fronde it offered a refuge to Louis XIV. and Mazarin. Henry III. made it an apanage for his brother the duke of Anjou. At a later period it passed to the duke of Conti. Down to the Revolution it remained a monastic town. Philip the Bold, founder of the house of Burgundy, the architects Pierre and Jacques Lemercier, and Tronson-Ducondray, one of the defenders of Marie Antoinette, are among the natives of Pontoise.

**PONTOON.** Pontoons are vessels employed to support the roadway of floating bridges. They may be either open or closed, heavy and only movable when floated, or light enough to be taken out of the water and transported overland, as when required to form part of the equipment of an army in the field.

From time immemorial floating bridges of vessels bearing a roadway of beams and planks have been employed to facilitate the passage of rivers and arms of the sea. Xerxes crossed the Hellespont on a double bridge, one line supported on three hundred and sixty, the other on three hundred and fourteen vessels, anchored head and stern with their keels in the direction of the current. Darius threw similar bridges across the Bosphorus and the Danube in his war against the Scythians, and the Greeks employed a bridge of boats to which he poured his army in their retreat from Persia. Float-union. Stella's *6th* repeated. constructed over rivers fifty days; nor did his mother long. scholar's old age. Pontano had requirements of the

country; and to this day many of the great rivers in India are crossed, on the lines of the principal roads, by floating bridges, which are for the most part supported on boats such as are employed for ordinary traffic on the river.

But light vessels which can be taken out of the water and lifted on to carriages are required for transport with an army in the field. Alexander the Great occasionally carried with his army vessels divided into portions, which were put together on reaching the banks of a river, as in crossing the Hydaspes; he is even said to have carried his army over the Oxus by means of rafts made of the hide tents of the soldiers stuffed with straw, when he found that all the river boats had been burnt. Cyrus crossed the Euphrates on stuffed skins. In the 4th century the emperor Julian crossed the Tigris, Euphrates, and other rivers by bridges of boats made of skins stretched over osier frames. In the 17th century the Germans employed timber frames covered with leather as pontoons, and the Dutch similar frames covered with tin; and the practice of carrying about skins to be inflated and employed for the passage of troops across a river, which was adopted by both Greeks and Romans, still exists in the East, and has been introduced into America in a modified form, india-rubber being substituted for skins.

Pontoons have been made of a variety of forms and of almost every conceivable description of material available for the purpose of combining the two essential qualities of transportability over land and power of support in water. As these qualities are not only distinct but conflicting, one of them has been frequently sacrificed to the other. Thus history records many instances of bridges having failed because incapable of supporting all the weight they were called on to bear, or of resisting the force of the current opposed to them; it also records instances of important strategical operations being frustrated because the bridge equipment could not be brought up in time to the spot where it was wanted. Numerous expedients for lightening the equipment have been suggested, in America more particularly; but the proposers have not always remembered that if a military bridge is intended to be carried *with* an army it is also intended to *carry* the army, with its columns of infantry and cavalry, its numerous waggons, and its ponderous artillery, and it ought to do so with certainty and safety, even though a demoralized rabble should rush upon it in throngs.

Pontoons have been made of two forms, open as an undecked boat, or closed as a decked canoe or cylinder. The advantage claimed for the closed pontoon is that it cannot be submerged by the river, but only by having to bear a greater load than its buoyancy admits of; the disadvantages are that it is difficult to make and keep water-tight, it requires special saddles for the support of the baulks which carry the roadway, and it cannot be conveniently used as a row-boat. During the Peninsular War the English employed open bateaus, as did and still do all the other European nations; but the experience gained in that war induced the English to abandon the open bateau; for if large it was very difficult to transport across country, and if small it was only suited for tranquil streams, being liable to fill and sink should the river rise suddenly or become disturbed by the wind. Thus closed pontoons came to be introduced into the British army. General Colleton devised the first substitute for the open bateau, a buoy pontoon, cylindrical with conical ends and made of wooden staves like a cask. Then General Pasley introduced demi-pontoons, like decked canoes with pointed bows and square sterns, a pair, attached sternwise, forming a single "pier" of support for the roadway; they were constructed of light timber frames covered with sheet copper and were decked with wood; each demi-pontoon

was divided internally into separate compartments by partitions which were made as water-tight as possible, and also supplied with the means of pumping out water; when transported overland with an army, a pair of demi-pontoons and the superstructure of one bay formed the load for a single carriage weighing 3110 lb when loaded. The Pasley was superseded by the Blanshard pontoon, a tin coated cylinder with hemispherical ends, for which great mobility was claimed, two pontoons and two bays' superstructure being carried on one waggon, giving a weight of about 5000 lb, which was intended to be drawn by four horses. The Blanshard pontoon was long adopted for the British army, but it is now being discarded; experiments made with it in peace time showed that it would probably break down under the strain of actual warfare, and efforts were constantly made to improve on it; when immersed to a greater depth than the semi-diameter it became very unstable and lively under a passing load, a defect which Serjeant-Major Forbes proposed to remedy by giving it a triangular instead of a circular section, thus increasing the stability by presenting a continually increasing area of bearing surface up to the level of total immersion; but the angles of these pontoons were found so liable to injury as to counterbalance any advantages over the cylinders.

After many years' experience of the closed pontoon the English engineers came to the conclusion that it was desirable to return to the form of the open bateau to which the engineers of all the Continental armies had meanwhile constantly adhered. Captain Fowke, R.E., invented a folding open bateau, made of water-proof canvas attached to sliding ribs, so that for transport it can be collapsed like the bellows of an accordion and for use it can be extended by a pair of stretchers; it is very mobile, but it is also deficient in power of support, for whereas the buoyancy due to the outline form out of the water is 13,600 lb the actual buoyancy in the water is only 8640 lb, because of the cavities in the canvas between the ribs which are formed by the pressure of the water outside; moreover, the surface irregularities cause the pressure exerted by a current upon a bridge formed of these collapsible pontoons to be about three times as much as upon one of equal power formed with Blanshard's or Pasley's pontoons; there is thus great risk of the bridge being carried away by a strong current.

The following table shows the powers of various pontoons at present or recently in use by different nations. The "working power of support" has been calculated in most instances by deducting from the "available buoyancy" one-fourth for open and one-tenth for closed vessels:—

*The Powers of Various Pontoon Bridges.*

Pontoon.	Length.	Displacement of Pontoon.	Actual Buoyancy of Pontoon.	Weight of Pontoon minus one half of superstructure.	Available Buoyancy.	Working Power of Support.	Central Interval in Bridge.	Power per Linear Foot of Roadway.	Greatest Ordinary Load per Foot of Roadway.	Width of Roadway.	Greatest Possible Load at 100 lb per Foot Superficial of Roadway.

In the English and French equipment the pontoons were originally made of two sizes, the smaller and lighter for the "advanced guard," the larger and heavier for the "reserve"; in both equipments the same size pontoon is now adopted for general requirements, the superstructure being strengthened when necessary for very heavy weights. The Austrian and Italian pontoons are made in three pieces, two with bows and a middle piece without; not less than two pieces are ordinarily employed, and the third is introduced when great supporting power is required, but in all cases a constant interval is maintained between the pontoons. On the other hand in the Prussian, Russian, Dutch, and American and in the English Blanshard equipments greater supporting power is obtained not by increasing the number of supports but by diminishing the central interval between the pontoons. Within certain limits it does not matter whether the buoyancy is made up of a large number of small or a small number of large vessels, so long as the water-way is not unduly contracted and the obstruction caused to a swift current dangerously increased; but it is to be remembered that pontoon bridges have failed as frequently from being washed away as from insufficient buoyancy.

On comparing the "available buoyancy" with the "greatest possible load at 100 lb per foot superficial of roadway" for each of the bridge equipments in the preceding table, it will be seen that very few of the bridges are really capable of carrying the maximum load they may be called on to bear. Strictly speaking the roadway superficies should in all instances be proportioned to the buoyancy of the pontoon, or, as the central interval between the pontoons cannot be reduced below certain limits, the width of the roadway should be proportioned to the buoyancy; in other words the "chesses" or planks which form the roadway should be made of a shorter length for a bridge which is designed for light traffic than for one which is designed for heavy traffic. The employment of chesses of different lengths for the pontoon equipment of an army would, however, be very inconvenient and troublesome, and this has led to the adoption of a constant breadth of roadway, on the understanding that the traffic will always be controlled by the officer in charge of the bridge.

The latest form of pontoon for the English army is one with which the name of Colonel Blood, R.E., is mainly associated. Its powers are given in the lowest line of the preceding table. It is an open bateau with decked ends and sides partly decked where the rowlock blocks are fixed. It consists of six sets of framed ribs connected by a deep keelson, two side streaks, and three bottom streaks. The sides and bottom are of thin yellow pine with canvas secured to both surfaces by india-rubber solution, and coated outside with marine glue. The central interval between the pontoons in forming a bridge is invariably maintained at 15 feet; for the support of the roadway five baulks are ordinarily employed, but nine for the passage of siege artillery and the heaviest loads; they fit on to saddles resting on central saddle beams. The pontoons are not immersed to within 1 foot of the tops of their "coamings" when carrying ordinary loads, as of infantry in marching order "in fours" crowded at a cheek, or the 16-pounder gun, which weighs 4800 lb; nor are they immersed to within 6 inches when carrying extraordinary loads, such as disorganized infantry, or the 64-pounder gun weighing 11,100 lb. In designing this pontoon the chief points attended to were—(1) improvement in power of support, (2) simplification in bridge construction, (3) reduction of weight in transport, and (4) adaptation for use singly as boats for ferrying purposes. One pontoon with the superstructure for a single bay constitutes a load for one waggon, with a total weight behind horses of about 4500 lb.

For the British army in India the standard pontoon for many years was the Pasley; it was seldom used, however, for boats could almost always be procured on the spot in sufficient numbers wherever a floating bridge had to be constructed. Of late years an equipment has been prepared for the Indian army of demi-pontoons, similar to the Blood pontoon cut in half, and therefore more mobile; each has a bow and a square stern, and they are joined at the sterns when required to form a "pier"; they are fitted with movable covers and can therefore be used in much rougher water than pontoons of the home pattern, and their power of support and breadth of roadway are the same.

For the British army there is a light form of the Blanshard pontoon suitable for infantry unencumbered, guns unlimbered, and cavalry in single file. The Berthou collapsible boat, for infantry in single file, is also employed; when open it is 9 feet long and 4 feet wide; it weighs 109 lb with a pair of oars and a removable thwart or seat (to enable it to be used as a boat), and can be slung on to a bamboo and carried by two men; the superstructure for one bay weighs 97 lb, and is also carried by two men; the width of roadway is 18 inches; twelve boats are required to bridge a stream 100 feet in width.

The india-rubber pontoon does not appear to have been generally employed even in America, where it was invented. The engineer officers with the army of the Potomac, after full experience of the india-rubber pontoon and countless other inventions of American genius, adopted the French equipment, which they found "most excellent, useful, and reliable for all military purposes." The Russians in crossing the Danube in their war with Turkey in 1878 employed the Austrian equipment.

PONTOPPIDAN, ERIC (1698–1764), a learned Danish author, was born at Aarhus on August 24, 1698, and studied divinity at the university of Copenhagen. On finishing his education he was appointed travelling tutor to several young noblemen in succession, and in 1735 he became one of the chaplains of the king. In 1738 he was made professor extraordinarius of theology at Copenhagen, and in 1747 bishop of Bergen, Norway, where he died on December 20, 1764.

His principal works are—*Theatrum Daniæ veteris et modernæ* (4to, 1730), a description of the geography, natural history, antiquities, &c., of Denmark; *Gesta et Vestigia Danorum extra Daniæ* (2 vols. 8vo, 1740), of which laborious work it is enough to remark that it was written before the rise of the modern historical school; *Annales Ecclesiæ Daniæ* (4 vols. 4to); *Marmora Danica Selectiora* (2 vols. fol., 1739–41); *Glossarium Norvegicum* (1740); *Det første Forsøg paa Norges naturlige Historie* (4to, 1752–54; Eng. trans., *Natural History of Norway*, 1755), containing curious acconuts, often referred to, of the Kraaken, sea-serpent, and the like; *Origines Hafnienses* (1760). His *Danske Atlas* (7 vols. 4to) was mostly posthumous.

PONTORMO, JACOPO DA (1494–1557), whose family name was CARUCCI, a painter of the Florentine school, was born at Pontormo in 1494, son of a painter of ordinary ability, was apprenticed to Leonardo da Vinci, and afterwards took lessons from Pier di Cosimo. At the age of eighteen he became a journeyman to Andrea del Sarto, and was remarked as a young man of exceptional accomplishment and promise. Later on, but still in early youth, he executed, in continuation of Andrea's labours, the Visitation, in the cloister of the Servi in Florence—one of the principal surviving evidences of his powers. The most extensive series of works which he ever undertook was a set of frescos in the church of S. Lorenzo, Florence, from the Creation of Man to the Deluge, closing with the Last Judgment. By this time, towards 1546, he had fallen under the dangerous spell of Michelangelo's colossal genius and superhuman style; and Pontormo, after working on at the frescos for eleven years, left them incomplete, and the object of general disappointment and disparagement. They were finished by his leading pupil Angelo Bronzino, but have long since vanished under whitewash. Among the best works of Pontormo are his portraits, which include the likenesses of various members of the Medici family; they are vigorous, animated, and highly finished. He was fond of new and odd experiments both in style of art and in method of painting. From Da Vinci he caught one of the marked physiognomic traits of his visages, smiles and dimples. At one time he took to direct imitation or reproduction of Albert Dürer, and executed a series of paintings founded on the Passion subjects of the German master, not only in composition, but even in such peculiarities as the treatment of draperies, &c. Italian critics, both contemporary and of later date, have naturally regarded this as a very perverse aberration. Pontormo died of dropsy on 2d January 1557, mortified at the ill success of his frescos in S. Lorenzo; he was buried below his work in the Servi. He was a man of solitary self-neglectful habits, a slow worker, receiving comparatively little aid from scholars, indifferent to gain or distinguished patronage, and haunted by an instinctive horror of death.

PONTUS was the name given in ancient times to an extensive tract of country in the north-east of Asia Minor, bordering on Armenia and Colchis (see vol. xv. Plate II.). It was not, like most of the divisions of Asia, a national appellation, but a purely territorial one, derived from its proximity to the Euxine, often called simply Pontus by the Greeks. Originally it formed part of the extensive region of Cappadocia, which in early ages extended from the borders of Cilicia to the Euxine; but afterwards it came to be divided into two satrapies or governments, of which the northernmost came to be distinguished as "Cappadocia on the Pontus," and thence simply as "Pontus." The term is not, however, found either in Herodotus or Xenophon, though the latter traversed a considerable part of the region, and it is probable that it did not come into general use until after the time of Alexander the Great. Under the Persian empire the province continued to be governed by a satrap, nominally subject to the great king, but apparently enjoying virtual independence, as no

mention occurs in Xenophon of the Persian authorities in this part of Asia. The first of these local satraps who assumed the title of king was Ariobarzanes, about the beginning of the 4th century B.C., who was reckoned the founder of the dynasty; but its history as an independent monarchy really begins with Mithradates II., who commenced his reign in 337 B.C. From this time Pontus continued to be ruled by a succession of kings of the same dynasty, mostly bearing the name of Mithradates, whose independence was respected by the Macedonian sovereigns of Asia, and who were able gradually to extend their power along the shores of the Euxine. The capture of the important city of Sinope by Pharnaces I. (about 153 B.C.) led to the extension of their frontier to that of Bithynia; while under Mithradates VI., commonly known as the Great, their dominion for a time comprised a large part of Asia Minor. The history of the reign of that monarch and his wars with the Romans will be found under the heading **MITHRADATES**. After his final defeat by Pompey in 65 B.C., Pontus was again confined within its original limits, but was united with Bithynia as a Roman province, and this union generally continued to subsist, though not without interruption, under the Roman empire. A portion of the original dominion of the kings of Pontus was, however, separated from the rest by Antony in 36 B.C., and placed under the government of a Greek rhetorician named Polemon, whose descendants continued to rule it till the reign of Nero, when it was finally annexed to the Roman empire (63 A.D.). Hence this part of the country came to be known as Pontus Polemoniacus, by which epithet it was still distinguished as a Roman province. The interior district in the south-west, adjoining Galatia, hence came to be known as Pontus Galaticus.

Pontus, in the proper sense of the term, as defined by Strabo, who was himself a native of the country, was bounded by the river Halys on the west, and by Colchis and the Lesser Armenia on the east. Its exact frontier in this direction is not specified, but it may be taken as extending as far as the mouth of the river Acampsis. The region thus limited may be considered as divided into two portions, differing much in their physical characters. The western half presents considerable plains and upland tracts in the interior, stretching away till they join the still more extensive uplands of Cappadocia and Galatia. Besides the great river Halys that forms its boundary on the west, this region is traversed by the river Iris, and its tributary the Lycus, both of which have their rise in the highlands on the frontiers of Armenia, and are very considerable streams, flowing through fertile valleys. The Thermodon, which enters the Euxine a little to the east of the Iris, is a much less important stream, though celebrated from its connexion with the fable of the Amazons. On the other hand the eastern portion of Pontus, between Armenia and the Euxine, is throughout a very rugged and mountainous country, furrowed by deep valleys descending from the inland range of mountains, known to the ancients as Paryadres, which has a direction nearly parallel to the sea-coast, and is continued to the frontiers of Colchis under the name of Scydises and various other appellations. These mountains have in all ages been almost inaccessible, and even in the time of Strabo were inhabited by wild tribes who had never been really reduced to subjection by any government. But the coast from Trebizond westward is one of the most beautiful parts of Asia Minor, and is justly extolled by Strabo for its wonderful productiveness in fruits of every description.

The population of the greater part of Pontus was undoubtedly of the same race with that of Cappadocia, of which it originally formed a part, and was therefore clearly

of Semitic origin.<sup>1</sup> Both nations were frequently comprised by the Greeks under the term *Leucosyri* or White Syrians. But the rugged mountain districts in the north-east, towards the frontiers of Colchis and Armenia, were occupied by a number of semi-barbarous tribes, of whose ethnical relations we are wholly ignorant. Such were the Chaldaeans or Chalybes (identified by the Greeks with the people of that name mentioned by Homer), the Tilareni, the Mosynœci, and the Macrones. Some light is thrown on the manners and condition of these people by Xenophon, who traversed their country on his march from Trapezus to Cotyora (*Δανάβ.*, v.) but we have otherwise hardly any information concerning them.

The sea-coast of Pontus, like the rest of the south shore of the Euxine, was from an early period studded with Greek colonies, most of them of Milesian origin, though in many cases deriving their settlement directly from Sinope, itself a colony of Miletus. Next to that city, between the mouth of the Halys and that of the Iris, stood Amisus, originally a colony direct from Miletus, but which subsequently received a body of Athenian settlers. It was one of the most flourishing of the Greek colonies on this coast, and is still a considerable town under the name of Samsun. Proceeding eastward from thence, we find Side, called in later times Polemonium; Cotyora, a colony of Sinope, where Xenophon embarked with the ten thousand Greeks; Cerasus, afterwards named Pharnacia; and Trapezus, also a colony of Sinope, which was a flourishing and important town in the days of Xenophon, but did not attain till a later period to the paramount position which it occupied under the Roman and Byzantine empire, and which it still retains under the name of **TREBIZOND** (*q.v.*).

But, besides these Greek settlements, there were in the interior of Pontus several cities of considerable importance, which were of native origin, though they had gradually received a certain amount of Greek culture. The principal of these were Amasia, on the river Iris, the birth-place of Strabo, which was made the capital of his kingdom by Mithradates the Great, but had previously been the burial-place of the earlier kings, whose tombs are still extant, and have been described by Hamilton and other travellers; Comana, higher up the valley of the same river, which, like the place of the same name in Cappadocia, was consecrated to a native goddess named Ma, identified by Strabo with the Greek Enyo, and derived great celebrity from its sacred character, having a large fixed population under the direct government of the priests, besides being the resort of thousands of pilgrims; Zela, nearer the frontier of Galatia, which was in like manner consecrated to a goddess named Anaitis; and Cabira, in the valley of the Lycus, afterwards called Neocæsarea, a name still retained in the abbreviated form of the modern Niksar. Several smaller towns are mentioned by Strabo as giving name to the surrounding districts, of which he has left us the names of not less than fifteen; but these obscure appellations of local divisions are in themselves of little interest, and for the most part not mentioned by any other writer. (E. H. B.)

**PONTUS DE TYARD** (c. 1521–1605), one of the famous Pleiade who helped to reform French literature in the 16th century, was the highest in rank and the most affluent in fortune of the seven. He was indeed in some sort an anticipator of Ronsard and Du Bellay, for his *Erreurs Amoureuses* preceded their work. He was seigneur of Bissy in Burgundy, was born at the seignorial house in

<sup>1</sup> Such at least was the general opinion of Greek writers. The Semitic or Armenian origin of the Cappadocians has, however, in modern times been questioned by Nöldeke and other authorities on Semitic ethnology.

or about 1521, and died at a great age at Bragny on the Saône, another seat of his, on September 25, 1605. He was thus the last survivor as well as one of the eldest of the group. His early poems, the *Erreurs Amoureuses*, originally published in 1549, were augmented with other works in successive editions till 1573. Pontus de Tyard published *Discours Philosophiques* in 1587, and appears to have been a man of extensive knowledge and just thought. He was, moreover, a courtier and official of some standing for many years, and, entering the church, was made count-bishop of Châlon-sur-Saône. In this high position he bore a character for political and religious moderation. On the whole his poetry is inferior to that of his companions, but he was one of the first to write sonnets in French (the actual priority belongs to Mellin de St Gelais); and one of these, the beautiful Sonnet to Sleep (it has been noted that the poetical name of his mistress in the *Erreurs* is, oddly enough, Pasithea, the name of the nymph beloved classically by the god of sleep), is a very notable and famous piece. It is also said that Pontus de Tyard introduced the sestet into France, or rather reintroduced it, for it is originally a Provençal invention.

PONTYPOOL, a town and urban sanitary district of Monmouthshire, England, situated on an acclivity above the river Avon Lwyd, on the Monmouthshire Canal, and on the Great-Western and Monmouthshire Railways, 8 miles north of Newport. The town-hall, in the Doric style, dates from 1856, the market-house from 1846, and the Baptist theological college from 1856. At one period Pontypool was famed for its japanned goods, invented by Thomas Allwood, a native of Northampton, who settled in the town in the reign of Charles II., but the manufacture has long been transferred altogether to other towns. The present prosperity of Pontypool is due to its situation on the edge of the great Pembrokeshire coal and iron basin. The earliest record of trade in iron is in 1588, but it was developed chiefly in the beginning of the 18th century by the Hanburys, the proprietors of Pontypool Park. The town possesses large forges and iron-mills for the manufacture of iron-work and tin-plate. The population of the urban sanitary district (area 800 acres) in 1871 was 4834, and in 1881 it was 5244.

PONTYPRIDD, sometimes also called NEWBRIDGE, a market town of Glamorganshire, Wales, situated on the Taff at its junction with the Rhondda, and on the Glamorganshire Canal, 12 miles north-north-west from Cardiff and 12 south from Merthyr-Tydfil. It receives its name from a remarkable bridge of one arch spanning the Taff, erected by William Edwards, a self-taught mason. The bridge is a perfect segment of a circle, the chord being 140 feet, and the height at low water 36 feet. A three-arched bridge was erected close to it in 1857. The principal buildings are the court-house, St Catherine's church, the masonic hall, and the town-hall. Near the town is a far-famed rocking stone 9½ tons in weight, surrounded by so-called Druidical remains. In the beginning of the century Pontypridd was an insignificant village, and it owes its progress chiefly to the coal and iron in the neighbourhood. It possesses anchor, chain, and cable works, chemical works, and iron and brass foundries. The population in 1881 was 12,317.

PONZA, the principal island of a small volcanic group, the Pontian, Pontine, or Pontinian Islands (*Insulæ Pontinæ*, *Isole Ponze*), which lie 20 miles off the Circeian promontory (Monte Circello), the northern end of the Gulf of Gaeta, on the west coast of Italy. The two smaller islands are Palmarola (ancient *Palmaria*) and Zannone (*Simonia*), neither inhabited. Ponza is 5 miles long and very irregular in outline; its soil is fertile; and in 1881 it had

3828 inhabitants. The old fortress is used as a penal establishment.

A Roman colony with Latin rights was settled on Pontia in 313 B.C. Under the empire the island was a place of banishment for political offenders. Nero, the eldest son of Germanicus, here perished by command of Tiberius; here the sisters of Caligula were confined; and here, or in Palmaria, Pope Sylvester died. A Benedictine monastery was built on Ponza, and in 1572 Cardinal Farnese, as commendatory of the monastery, claimed to exercise lordship over the island. From the duke of Parma, who obtained possession in 1588, the feudal authority passed with Elizabeth to Philip V. of Spain. Ferdinand IV. attracted the inhabitants of Torre del Greco to the island by gifts of land and money. During the first French empire it was occupied and fortified by the English and Sicilian forces.

See Tricoll, *Monografia per le isole del gruppo Ponziense*, Naples, 1855; Mattel, *L'Archipelago Ponziense*, Naples, 1857; and Doelter, *Vorläufige Mittheilung über den geol. Bau der Pontinischen Inseln*, Vienna, 1875.

POOLE, a market town, municipal borough, county in itself, and seaport of Dorsetshire, on the south coast of England, is picturesquely situated on a peninsula between Holes Bay and Poole Harbour, 30 miles east from Dorchester and 120 south-west of London. The churches are modern, and possess no features of special interest. Among the principal public buildings are the town-house, 1721; the guild-hall, formerly the market-house, 1761; the old town-hall, built in 1572; the custom-house; and the mechanics' institute. On Brownsea Island in the middle of Poole Harbour is a small castle erected as a fortress by Elizabeth and strengthened by Charles I. At low water Poole Harbour is entirely emptied except a narrow channel, but at full tide the water covers an area about 7 miles long by about 4½ broad. The quays lined with warehouses are about one mile in length, and can be approached by vessels of very large tonnage. There is a large general trade with the British colonies and the United States, and an important coasting trade, especially in corn to London, and Purbeck clay to the Staffordshire potteries. In 1883 the number of vessels that entered the harbour was 933 of 81,003 tons, the number that cleared 874 of 77,948 tons. Some shipbuilding is carried on, and there are manufactures of cordage, netting, and sail-cloth. The town also possesses large potteries, decorative tileworks, iron-foundries, engineering works, agricultural implement works, and flour-mills. The area of the borough is 5111 acres, with a population in 1871 of 10,129, and in 1881 of 12,310 (5820 males and 6490 females).

Poole derives its name from being nearly surrounded by a sheet of water. There was a Roman road between it and Wimbourne. It is not mentioned in Domesday, being included in Canford, but it enjoyed certain immunities before 1248, when it received a charter from William Longsword. In the reign of Edward III. it supplied four ships and 94 men for the siege of Calais. Much of its succeeding prosperity was due to the presence of Spanish merchants, and after the outbreak of war with Spain in the reign of Elizabeth its trade for a time declined. Its charter was extended by Elizabeth, who reincorporated it, and created it into a county in itself. It has a sheriff elected annually, and a separate court of quarter sessions. It is divided into two wards, and is governed by a mayor, six aldermen, and eighteen councillors. It returned two members to parliament as early as the reign of Edward III., but one only from 1868 to 1885.

See Hutchins, *History of Poole*, 1788; Sydenham, *History of Poole*, 1839; Hutchins, *History of Dorset*, 3d ed.

POOLE, MATTHEW (1624–1679), author of a learned though now almost wholly antiquated *Synopsis Criticorum Biblicorum*, was born at York in 1624, was educated at Emmanuel College, Cambridge, and from 1648 till the passing of the Act of Uniformity held the rectory of St Mary le Querne, London. Subsequent troubles led to his withdrawal to Holland. He died at Amsterdam in 1679.

Besides the work with which his name is principally associated (*Synopsis Criticorum Biblicorum*, 5 vols. fol., 1669–76), he wrote *Annotations on the Holy Bible*, as far as to Isa. lviii.; the work was subsequently completed by several of his Nonconformist brethren, and published in 2 vols. fol. in 1683. He was also the author of numerous controversial tracts.

POOLE, PAUL FALCONER (1806-1879), an eminent English painter, was born at Bristol in 1806. He was self-taught in the strictest sense, and to this deficiency in art training must be ascribed the imperfect drawing of the human figure which is to be observed in most of his work. But, in spite of this drawback, his fine feeling for colour, his poetic sympathy, and his dramatic power have gained for him a high position among British artists. Gifted with an imagination of a high order, he boldly attempted lofty historical themes, and, if the result is not always equal to the vigour of his conception, we can easily see that the shortcoming was due to his imperfect education in art. His pictures show him to belong to that comparatively small class of English painters who are keenly sensitive to the influence of beauty and of passion, rising on occasion to ambitious flights of fancy, and dominated by strong dramatic impulse. A keen observer of nature, but generally viewing it in a broad comprehensive aspect, he was truly a poet-painter, using the effects of a summer sky or of angry clouds to harmonize with the subject of his picture and to enforce its story. In his early days Poole worked along with T. Danby, and it is easy to trace the bond of sympathy between the two painters.

Poole's life was the simple uneventful record of the career of the artist. He exhibited his first work in the Royal Academy at the age of twenty-five, the subject being the Well—a scene in Naples. There was an interval of seven years before he again exhibited his Farewell, Farewell, in 1837, which was followed by the Emigrant's Departure, Hermann and Dorothea, and By the Waters of Babylon. This last picture attracted much attention from the fine poetic imagination which it displayed. In 1843 his position was made secure by his Solomon Eagle, and by his success in the Cartoon Exhibition, in which he received from the Fine Art Commissioners a prize of £300 sterling. After his exhibition of the Surrender of Sym House he was elected an Associate of the Royal Academy in 1846, and was made an Academician in 1861. In 1855 he received a medal of the third class at the Paris Universal Exhibition. His enthusiasm for his art was rewarded by success in life, though like many artists he passed through much hardship in his early days. He died in 1879, in his house at Hampstead, in his seventy-third year. In person he was tall and well built, with a lofty forehead, grey eyes, and short beard. The portrait sketch by Frank Holl, R.A., gives a very good idea of him in his last days,—a shy man but genial to his friends, fond of conversation and well read, especially in his favourites Shakespeare, Shelley, Spencer, and Chaucer, who were the sources of inspiration of many of his works.

Poole's subjects easily divide themselves into two orders—one, without doubt the earlier, idyllic, the other dramatic. Of the former his May Day is a typical example. A rustic beauty crossing a brook, or resting on a hill side under bushes flecked with the light and shade of a bright sun and with cirrus clouds floating in a blue sky, is the frequent motive of these works, which are full of simple enjoyment of a beautiful country life. But in his later style he rises to loftier subjects and treats them powerfully. Of both styles there were excellent examples to be seen in the small collection of his works shown at Burlington House in the Winter Exhibition of 1882-84. These collected pictures recalled the attention of the public to a painter who had suffered neglect for some years, alike from his own deficiencies as a draughtsman and also from a want of sympathy with the poetical character of his paintings, which never could have been popular with the ordinary public. His reputation will stand or fall by the criticism of this gathering of his pictures, small though it was. There was to be seen one of his early dramatic pictures, painted in 1842, Solomon Eagle exhorting the People to Repentance during the Plague of 1665, terrible in its ghastly force. Though exaggerated in the expression of horror and agony, weak in drawing, and defective in colour, it is clearly the work of a powerful imagination. To this class belong also the Messenger announcing to Job the Irruption of the Sabeans and the

Slaughter of the Servants (exhibited in 1850), and Robert, Duke of Normandy and Arletta (1849). Finer examples of his more mature power in this direction are to be found in his Prodigal Son, painted in 1859; the Escape of Glacius and Ione with the blind girl Nydia from Pompeii (1860); and Constance sent adrift by the Constable of Alla, King of Northumberland, painted in 1865. Here Poole rises to a lofty height, and succeeds fully in realizing the impression he aims at. The expression of anguish and of resignation at Constance clasps her child to her bosom and turns her moon-lit face to heaven is rendered with great power, while the effect is heightened by the stormy sky, the dark rocks, and the angry sea.

More peaceful than these are the Song of Troubadours (painted 1854) and the Goths in Italy (1851), the latter an important historical work of great power and beauty. It represents the easy luxurious insolence of the barbarian conquerors, lying stretched on the grass in the gardens of Lucullus and Cicero, while the captive daughters of proud senators wait on them and offer wine in golden goblets. In the background is a circular temple overhanging the sea, while overhead is a beautiful sky—altogether a bold feat to attempt, yet Poole has succeeded in giving a great representation of a striking page in history.

Of a less lofty strain, but still more beautiful in its workmanship, is the Seventh Day of the Decameron, painted in 1857. In this picture Poole rises to his full height as a colorist. "In the foreground is Philomena, seated on the shore of a lake surrounded by high mountains, playing on a harp; eleven figures are grouped round her in various positions," as described in the catalogue. The chief beauty of this work lies in its fine colour and quiet repose. The amphitheatre of rocky mountains reflected in the lake gives us a splendid example of Poole's power in landscape, which is large and broad in style. His treatment corresponded with his choice of subject. In his pastorals he is soft and tender, as in the Mountain Path (1853), the Water-Cress Gatherers (1870), the Shepton Maiden (1872). But when he turns to the grander and more sublime views of nature his work is bold and vigorous. Fine examples of this style may be seen in the Vision of Ezekiel of the National Gallery, Solitude (1876), the Entrance to the Cave of Mammon (1875), the Dragon's Cavern (1877), and perhaps best of all in the Lion in the Path (1873), a great representation of mountain and cloud form. This wild rocky landscape had a great fascination for him; every aspect of nature which showed the action of mighty force attracted him; hence his love of mountain sides scarred by ravines, and of trees torn and twisted by hurricanes. Caverns are a frequent theme; indeed he used to say that he had been haunted all his life by them, and that he would travel far to see a new one.

POONA, a district in the Deccan, Bombay, situated between 17° 54' and 19° 23' N. lat., and 73° 24' and 75° 13' E. long. It has an area of 5347 square miles, and is bounded on the N. by the districts of Nasik and Ahmednagar, on the E. by those of Ahmednagar and Sholapur, on the S. by the Nira river, separating it from Satara and Phaltan, and on the W. by the Bhore state and Sahyadri Hills. Towards the west the country is extremely undulating, and numerous spurs from the hills enter the district. To the east it opens out into plains; but a considerable area is now being put under forest. Poona is watered by many streams which, rising in the Sahyadri range, flow eastwards until they join the Bhima, a river which intersects the district from north to south. The Great Indian Peninsula Railway runs through it, and affords an outlet for its produce through the Bhore Ghat to Bombay; another railway is about to be commenced which will put the district into communication with the southern Mahratta country. The Khadakvasla Canal, about 10 miles south-west of Poona, which it supplies with water, is one of its most important works. Although the district is not rich in minerals, trap rock suitable for road-making and stone for building purposes are found. Only in the west are wild animals met with, chiefly tigers, leopards, bears, and sambhar deer. The climate is dry and invigorating; the average annual rainfall is about 30 inches.

The population of the district in 1881 was 900,621 (455,101 males and 445,520 females), of whom 834,943 were Hindus, 42,036 Mohammedans, 1574 Parsis, 10,899 Jains, 9500 Christians, and 1783 of other religions. The only towns with a population exceeding 10,000 are POONA (q.v.), Poona cantonment (30,129), and Junnar (10,373).

Agriculture supports about half the population. Of a total area

of Government culturable land of 1,924,630 acres, 1,775,583 were cultivated during 1882-83. Of these 181,395 acres were fallow land and occupied waste, leaving 1,594,188 acres under actual cultivation, of which 28,035 were twice cropped. The chief products are cereals (chiefly jowari and bajri) and pulse, and the principal manufactures of the district are silk robes, coarse cotton cloth, and blankets; its brass and silver work is much admired. The gross revenue in 1882-83 was £180,736, of which the land tax yielded £111,740, stamps £18,790, and excise £31,160.

*History.*—The district passed from the last Hindu dynasty which reigned at Deogiri to the Mohammedans between 1294 and 1312, and under the Bahmani kings the Ghat country was thoroughly subdued. On the disruption of the Bahmani kingdom after the revolt of the governors of the provinces, the district fell to the share of the Ahmednagar kings and from them it passed to the Moguls, when the Nizamshahi dynasty finally came to an end in 1637. The country north of the Bhima, including Junnar, was annexed to the Mogul territory, and that south of it was made over to Bijapur. The power of the latter was, however, declining, and gave an opportunity to the Mahratta chiefs to unite and assert themselves, and ended in their establishing a Mahratta kingdom at Satara. Intrigues at the palace led to the supremacy of the peshwas and the removal of the capital to Poona, where many stirring scenes in Mahratta history have been enacted. Holkar defeated the peshwa under its walls, and his flight to Bassein led to the treaty by which he put himself under British protection; he was reinstated in 1802, but, unable to maintain friendly relations, he attacked the British at Kirkee in 1817, and his kingdom passed from him.

POONA, the chief town of the above district, is situated in 18° 31' N. lat. and 73° 55' E. long., in a treeless plain about 2000 feet above the sea and overlooked by the Ghats, which rise 1000 feet above the plain. Its area is about 4 square miles, with a population in 1881 of 99,622—males 50,814, females 48,808. The town stands on the right bank of the Muta river, and is about 80 miles south-east of Bombay. Until the year 1817, when it was taken by the British, the city was the residence of the peshwas of the Mahrattas.

**POOR LAWS.** Without embarking on an inquiry as to the causes of pauperism or the primary right of any persons to have their wants, however pressing, met by the state, it is sufficient to say that in Great Britain "there is no man so indigent or wretched but he may demand a supply sufficient for all the necessaries of life from the more opulent part of the community, by means of the several statutes enacted for the relief of the poor" (Blackstone). Moreover, apart from statute, by the common law of England the poor were sustainable "by parsons, rectors of the church, and the parishioners, so that none of them die for default of sustenance" (*Mirror*).

The great importance of the subject of relief of the poor is evinced, apart from other considerations, by the number of persons immediately affected, either as recipients of relief or as ratepayers, and by the sums expended in that relief. The number of paupers of all classes now in receipt of relief in England and Wales approaches 800,000, equivalent to a thirty-fourth part of the entire population, and relieved at a yearly cost of considerably more than £8,000,000, representing a charge of between six and seven shillings per head of the estimated population.

Of existing legislation a statute of the beginning of the 17th century (43 Eliz. c. 2, 1601) is the earliest, under which, by parochial taxation, parish officers are directed to provide a stock of materials for "setting the poor on work" (that is to say, persons "married or unmarried having no means to maintain them [and that] use no ordinary and daily trade of life to get their living by"), and further for setting to work their children; "and also competent sums of money for and towards the necessary relief of the lame, impotent, old, blind, and such others among them being poor and not able to work." The same statute enacts "that the father and grandfather and the mother and grandmother and the children of every poor old, blind, lame, and impotent person, or other poor person not able to work, being of a sufficient

ability, shall at their own charges relieve and maintain every such poor person."

Although the statute of Elizabeth is spoken of as the principal foundation of existing legislation relating to the poor, it is an error to say that the relief of the poor originated at that period. The common law of England has been already cited, and traces of poor laws, however far removed from a system, are found in all civilized states. An approximation to the principle may be discerned in the legislation of England at a very early period; and before the Norman Conquest laws of Athelstane, establishing a responsibility over households and landowners, although intended for good order and calculated to prevent the growth of vagabondage and violence, had also the effect of establishing reciprocal relations between the landless man and the landowner, between property and poverty, between the householder and the houseless,—casting upon one the duty of supervising the conduct and providing for the wants of the other, in some respects similar to the poor law of the present day. "The results of this legislation were likewise, it may be presumed, not very dissimilar, for the improvident and the indolent would endeavour, with the smallest amount of labour, to obtain the largest amount of assistance from the householder who was liable for their support and responsible for their conduct, whilst the householder would as certainly endeavour to obtain the largest amount of labour in return for the cost and responsibility to which he was subject." Again, so long as serfdom and villenage prevailed, whether to be traced to the Norman Conquest or not, there could be no call for any special provision for the destitute. "The persons who might, if free agents and in a destitute state, have been properly relieved out of a common stock, would as serfs or villeins have a claim on their masters, to whom they belonged, and who were bound to provide for them" (Nicholls). As those old ties became more relaxed the change to freedom was accompanied by some evils, and led to a great increase of vagrancy; and from a period commencing before the close of the 14th century there was a stream of legislation on the subject. An Act of 12 Richard II., after providing for labour to persons able to work (see LABOUR AND LABOUR LAWS, vol. xiv. p. 167), enacts "that beggars impotent to serve shall abide in the cities and towns where they may be dwelling at the time of the proclamation of this statute, and, if the people of the cities and towns will not, or may not, suffice to find them, that these, the said beggars, shall draw them to other towns within the hundred, rape, or wapentake, or to the towns where they were born, within forty days after the proclamation made, and there shall continually abide during their lives." This is the first enactment in which the impotent poor are directly named as a separate class, and on that account it has been mistakenly regarded as the origin of the English poor laws; but it makes no provision for their relief, and the chief characteristic of the statute is the fact of its having openly recognized the distinction between "beggars able to labour" and "beggars impotent to serve." Passing over intermediate legislation, by an Act passed in 1530, "directing how aged, poor, and impotent persons compelled to live by alms, shall be ordered, and how vagabonds and beggars shall be punished," justices of the peace were required to give licences under their seals to such poor, aged, and impotent persons to beg within a certain precinct as they should think to have most need; "and if any do beg out of his precinct he shall be set in the stocks two days and nights; and if any beg without such licence he shall be whipped, or else be set in the stocks three days and three nights, with bread and water only. And persons being whole and mighty in body, and able to labour, who shall beg, or be vagrants and not able to account how they get

none to go or sit openly a-begging." It is noteworthy that, except a penalty of 20s. imposed on a person refusing the office of gatherer, duties were enforced by ecclesiastical censure. The gatherers were required to account for the money; and if they refused the bishop of the diocese or ordinary was to compel them by censures of the church to account before such persons as he appointed. Further, if any person, being able to further the charitable work, "do obstinately and frowardly refuse to give towards the help of the poor or do wilfully discourage others from so charitable a deed," the parson, vicar, or curate, and churchwardens should "gently exhort him, and if he will not be so persuaded" then on certificate the bishop should send for him "to induce and persuade him by charitable ways and means, and so according to his discretion to take order for the reformation thereof" (5 & 6 Edw. VI. c. 2).

This statute was recognized in part after the accession of Mary, by altering the time of choosing collectors to Christmas and doubling the penalty for refusing to fill the office of collector, and moving wealthy parishes in cities and towns to contribute towards the relief of the poor in the less wealthy parishes. At the same time a material modification of the spirit of earlier legislation was effected by enabling justices to license the poor of parishes having more poor than they could relieve, to go begging into specified parishes, wearing a badge "both on the breast and back of their outermost garment" (2 & 3 P. & M. c. 5).

Eliza-  
bethan  
legisla-  
tion.

Early in Elizabeth's reign the spiritual persuasion towards obstinate and froward persons withholding contributions was strengthened by the aid of the civil power, by directing the bishop or ordinary to bind all obstinate persons by recognizance to appear at the next sessions; and then, the charitable and gentle persuasions of the justices failing, the latter could tax the obstinate person in a weekly sum according to good discretion, and in default commit him to jail until payment. A corresponding power was given to deal with collectors refusing to account (5 Eliz. c. 3). A few years later (1572) legislation took a more vigorous turn "for the punishment of vagabonds and for relief of the poor and impotent." The Act 14 Eliz. c. 5, reciting that "all the parts of this realm of England and Wales be presently with rogues, vagabonds, and sturdy beggars exceedingly pestered, by means whereof daily happeneth in the same realm horrible murders, thefts, and other great outrages, to the high displeasure of Almighty God, and to the great annoy of the common weal, and for avoiding confusion by reason of numbers of laws concerning the premises standing in force together," repealed the before-mentioned statutes of 22 Hen. VIII, 3 & 4 Edw. VI., and 5 Eliz. c. 3, and made provision for various matters, "as well for the utter suppressing of the said outrageous enemies to the common weal as for the charitable relieving of the aged and impotent poor people." Persons above fourteen and being rogues, vagabonds, or sturdy beggars, and "taken begging in every part of this realm, or taken vagrant, wandering and misordering themselves," were upon their apprehension to be committed to prison to the next sessions or jail delivery without bail, and on conviction "shall be adjudged to be grievously whipped, and burnt through the gristle of the right ear with a hot iron of the compass of an inch about, manifesting his or her roguish kind of life and his or her punishment received for the same." This judgment was not to be executed if after imprisonment "some honest person, valued at the last subsidy next before that time to five pounds in goods or twenty shillings in lands, or else some such honest householder as by the justices of the peace of the same county, or two of them, shall be allowed, will of his charity take such offender before the same justices into his service for one whole

year," under recognizance to keep this poor person for that period and to bring him, if still living, before the justices at the year's end; on the other hand the pauper departing within the year against the will of his master was to be whipped and burnt as above provided. The offender was absolved from a second punishment for a short time, but if after threescore days, and being of the age of eighteen or more, he "do eftsoons fall again to any kind of roguish or vagabond's trade of life," then the said rogue, vagabond, or sturdy beggar, from thenceforth was "to be taken, adjudged, and deemed in all respects as a felon," and should suffer as a felon,—subject, however, to like redemption as on the first charge, conditioned for two years' service; but offending a third time he was to "be adjudged a felon" and suffer pains of death and loss of lands and goods as a felon, without allowance or benefit of clergy or sanctuary. Offenders under fourteen were punishable by whipping or stocking as provided by the repealed statutes.

A clause defining persons subject to the above punishment throws a light on the manners of the age, and is, as well as its exceptive provisions, of considerable interest; but, as relating to vagrancy, and only indirectly to the relief of the really poor, it is not given here. It is to be observed, however, that the statute provided that it should be still lawful to masters and governors of hospitals to lodge or harbour impotent or aged persons by way of charity according to their foundation, and to give money in alms as provided by the terms of their foundation. Harsh as was the treatment of rogues, vagabonds, and sturdy beggars, it was not so cruel as the short-lived legislation of the reign of Edward VI. imposing slavery in its worst form on wandering serving men (see vol. xiv. p. 168).

Exceptional provision was made for persons provided with passes and safe conducts, as in former Acts. The statute goes on to say that, "forasmuch as charity would that poor, aged, and impotent persons should as necessarily be provided for as the said rogues, vagabonds, and sturdy beggars repressed," and that the former should have "convenient habitations and abiding places throughout this realm to settle themselves upon, to the end that they nor any of them should hereafter beg or wander about," and enacts that justices of the peace in their different divisions "make diligent research and inquiry of all aged, poor, impotent, and decayed persons born within their said divisions and limits, or which were there dwelling within three years next before this present parliament, which live, or of necessity be compelled to live by alms of the charity of the people that be or shall be abiding within the limits of their commissions and authorities," and to register in a book the names of the poor persons, and devise and appoint meet and convenient places at their discretion "to settle the same poor people for their habitations and abidings, if the parish within the which they shall be found shall not or will not provide for them." The justices were also to number the poor people and "set down what portion the weekly charge towards their relief and sustentation would amount to;" and, that done, the justices, mayors, and other officers should "by their good discretions" tax the inhabitants dwelling within these limits to such weekly charge, and appoint collectors and also overseers of the poor for one year. Much as by a previous statute of 1547, compulsory removal of poor people from parish to parish (except the leprous and bed-ridden), not born or not having dwelt in the place, was provided for. Poor people refusing to "be bestowed in any of the said abiding places, but coveting still to hold on their trade of beggiug," or afterwards departing, were for the first offence to suffer as rogues or vagabonds in the first degree of punishment, and for a second offence to suffer

the last degree of punishment already mentioned. The provisions as to putting out children of beggars contained in the statute of Edward VI. already noticed were repeated in nearly the same terms, but the age of male children was extended from eighteen to twenty-four for the duration of service.

The Act provided for justices' licencees for poor to beg, ask, and receive relief in other parishes under similar circumstances as badges had been granted under an earlier and repealed statute. The Act also contained many provisions and exceptions as to places and corporate bodies, and any person "able to further the charitable work" contemplated by the statute, and obstinately refusing to give towards the help and relief of the poor, or wilfully discouraging others from so charitable a deed, was to be summoned before justices to abide their order, and on refusal to be committed to jail, and "there to remain until he be contented with their said order, and do perform the same."

There is extant a letter addressed to Lord Burghley by a justice of the peace for Somerset, which shows that the great evils arising from habits of idleness amongst the poor began then to be understood, and strengthens the idea that one great object of the legislative provisions for the poor made about that time was to prevent able-bodied men from remaining unemployed. The writer advocated building houses of correction adjoining jails, to which vagrants, after conviction, should be transported "to be kept in work, except some person would take any of them into service,"—adding, "I dare presume to say the tenth felony will not be committed that now is" (Strype, *Annals of Church and State*).

In 1576 the statute 14 Eliz. c. 5 was explained and materially extended. "To the intent youth may be accustomed and brought up in labour, and then not like to grow to be idle rogues, and to the intent also that such as be already grown up in idleness, and so rogues at this present, may not have any just excuse in saying that they cannot get any service or work, and that other poor and needy persons being willing to labour may be set on work," it was ordained that within every city and town corporate, by appointment of the mayor and other head officer, and in every other market town or other place where the justices in their general sessions yearly shall think meet, shall be provided a stock of wool, hemp, flax, iron, or other stuff, as that country is most meet for, and being wrought to be delivered to collectors and governors of the poor. Any person refusing to work, or begging, or living idly, or, taking such work, spoiling or embezzling it in such wise that after monition given the minister and churchwardens and the collectors and governors think such person not meet to have any more work delivered to him, was to be taken, "in convenient apparel meet for such a body to wear," to the "house of correction" established by the Act, and under the government of overseers of such houses, called censors and wardens, "there to be straitly kept, as well in diet as in work, and also punished from time to time." To the houses of correction were also taken and set on work not only the persons mentioned but also such "as be inhabitants in no parish or taken as rogues, or who had been once punished as rogues, or by reason of the uncertainty of their birth or of their dwelling by the space of three years, or for any other cause, ought to be abiding and kept in the county." An additional clause of the Act, reciting that by the earlier Act of 14 Eliz. no "pain" was incurred by any impotent person who having a competent allowance provided within his parish wandered abroad without licence "loitering and begging," enacted that he was to be whipped, and for a second offence to "suffer as a rogue and vagabond" (18 Eliz. c. 3). The

"stock" for work and the houses of correction were provided "of all the inhabitants to be taxed;" but, "because it is to be hoped that many well-disposed persons, understanding the good success which will grow by setting people on work and avoiding of idleness, would from time to time give towards the sustentation and maintenance of that good purpose," persons were empowered during the next twenty years to give lands for the purposes without any licence of mortmain. A later Act, reciting that this power to erect hospitals or other abiding and working houses for the poor had not its due effect by reason that no person could erect such house without special licence from the crown by letters patent, dispensed with such licence for twenty years (39 Eliz. c. 5).

The numerous charities and endowments and foundations of almshouses by will and otherwise of the 16th and 17th centuries, still extant in numerous buildings throughout the country, are illustrations of the spirit of the legislation here referred to. It is not improbable that legislation sometimes prompted the donors, but more probable that such legislation was a reflex of the general disposition prevalent for generations after the ordinary channels of voluntary charity were obstructed.

In 1597 considerable progress was made towards establishing a system of poor laws, not so much by introducing novelties as by entering more specifically into details, and especially by defining the legislation of some twenty years earlier (18 Eliz. c. 3) in the same reign. The appointment of overseers first mentioned in the earlier statute was provided for by enacting that the churchwardens of every parish and four subsidy men or other substantial householders nominated yearly in Easter week by justices should be called overseers of the poor of the same parish. The majority of the overseers were required with the consent of justices to set to work the children of persons unable to maintain them, and also all persons married or single and having no means of maintenance and no ordinary and daily trade of life to get their living by. The taxation weekly or otherwise of inhabitants and occupiers for providing a stock of flax, hemp, wool, thread, iron, and other necessary wares and stuff to set the poor on work, and also competent sums for the necessary relief of the lame, impotent, old, blind poor, unable to work, and the cost of erection, by leave of the lords of manors, of places of habitation on waste or common lands, was gathered according to the ability of the parish (or, if the parish was unable, then of other parishes in the hundred and county), and was enforceable by warrant of distress against every one refusing to contribute, but with a power of appeal against the cess or tax. Parents and children being of sufficient ability were required to maintain their poor children or parents. Any person whatsoever wandering abroad and begging in any place, by licence or without, was punishable as a rogue, with a proviso exempting poor persons asking relief in victuals only in the parishes where they dwelt (39 Eliz. c. 3).

Four years after came "the famous statute" of 1601 (43 Eliz. c. 2) already mentioned, out of which Dr Burn observes, "more litigation and a greater amount of revenue have arisen, with consequences more extensive and more serious in their aspect, than ever were identified with any other Act of Parliament or system of legislation whatever." It was the permanent establishment of the main provisions of the Act more than their novelty at the time the Act was passed that has fixed it as a kind of epoch in the legislation for the maintenance of the poor. The Act re-enacts, verbatim for the most part, the above-mentioned statute of 1597 (39 Eliz. c. 3). The material alterations were defining the rateable property, and extending and defining the family obligation of support, and also the

Statute of 1601.

formal apprenticing instead of placing out of children. The Act contains provisions for the rendering of accounts by the overseers.

The foregoing short review of legislation exhibits the very gradual change by which the maintenance of the poor became much more a temporal than a spiritual concern. So gradual was this change that in some places the law was neglected and in others abused. The material changes in legislation subsequent to the reign of Elizabeth must now be briefly alluded to.

James I. The efforts culminating in the statute of 1601 were not altogether attended with satisfactory results. At the end of eight years the Act 7 James I. c. 4 recited various defects. "Many wilful people finding that they, having children, have some hope to have relief from the parish wherein they dwell, and being able to labour, and thereby to relieve themselves and their families, do nevertheless run away out of their parishes and leave their families upon the parish." Again, and more prominently, "heretofore divers good and necessary laws and statutes have been made and provided for the creation of houses of correction, for the suppressing and punishing of rogues, vagabonds, and other idle, vagrant, and disorderly persons; which laws have not wrought so good effect as was expected, as well for that the said houses of correction have not been built according as was intended, as also for that the said statutes have not been duly and severely put in execution, as by the said statutes were appointed."

It was also convenient that the masters or governors of the houses of correction should have some fit allowance and maintenance "for their travel and care" to be had in the service, and also "for the relieving of such as shall happen to be weak and sick in their custody, and that the subjects of this realm should in no sort be over-charged, to raise up money for stocks to set such on work as shall be committed to their custody," and that there "shall be the more care taken by all such masters of the houses of correction that, when the country hath been at trouble and charge to bring all disorderly persons to their safe keeping, then they shall perform their duties in that behalf." Another grievance related to bastard children chargeable to the parish, of which more below.

The remedy for these and other grievances was putting in execution "all laws and statutes now in force made for the creating and building of houses of correction, and for punishing of rogues, vagabonds, and other wandering and idle persons," and providing restraints in the same direction, and for the efficient discharge of duties of treasurers, constables, and other officers in rendering accounts.

In 1630 a royal commission was issued to inquire into the neglect of the poor laws, and directions given for their enforcement.

Commonwealth. By a Commonwealth statute of 1656, reciting that "the number of wandering, idle, loose, dissolute, and disorderly persons is of late much increased by reason of some defects in the laws, and statutes heretofore made and provided for the punishment of rogues, vagabonds, and sturdy beggars (they being seldom taken begging), by means whereof divers robberies, burglaries, thefts, insurrections, and other misdemeanours have been occasioned, all and every idle, loose, and dissolute persons found and taken within the commonwealth of England, vagrant and wandering from their usual place of living or abode, and [who] shall not have such good and sufficient cause or business for such his or their travelling or wandering" as justices of the peace or mayors or other chief officers approved, were adjudged rogues, vagabonds, and sturdy beggars, within the statute 39 Eliz. c. 4, although not found begging; at the same time fiddlers and minstrels were also adjudged rogues, vagabonds, and sturdy beggars; and by a statute

of the same year persons having no visible estate, profession, or calling answerable to their rate of living expenses were indietable.

Soon after the Restoration attention was directed to the Charles existing state of the law and some of its defects. In II.

1662 the statute 13 & 14 Charles II. c. 12 recites that "the necessity, number, and continued increase of the poor, not only within the cities of London and Westminster, with the liberties of each of them, but also through the whole kingdom of England and dominion of Wales, is very great and exceeding burthensome, being occasioned by reason of some defects in the law concerning the settling of the poor, and for want of a due provision for the regulations of relief, and employment in such parishes or places where they are legally settled, which doth enforce many to turn incorrigible rogues, and others to perish for want, together with the neglect of the faithful execution of such laws and statutes as have formerly been made for the apprehending of rogues and vagabonds, and for the good of the poor." "For remedy whereof and for the preventing the perishing of any of the poor, whether young or old, for want of such supplies as may be necessary," numerous additional provisions were enacted. In the first place, "by reason of some defects in the law, poor people are not restrained from going from one parish to another, and therefore do endeavour to settle themselves in those parishes where there is the best stock, the largest commons or wastes to build cottages, and the most woods for them to burn and destroy, and, when they have consumed it, then to another parish, and at last become rogues and vagabonds, to the great discouragement of parishes to provide stocks, where it is liable to be devoured by strangers." Justices of the peace, upon complaint by the parish officers, within forty days after any such person's coming to settle as before mentioned in any tenement under the yearly value of £10, were empowered by warrant to remove such person to the parish where he was last legally settled either as a native, householder, sojourner, apprentice, or servant for not less than forty days, unless he gave sufficient security for the discharge of the parish.

In this way the law of settlement arose, with its numerous complications and modifications engrafted by subsequent legislation on this its original trunk. The statute of Charles, however, allowed (§ 3) any person "to go into any county, parish, or place to work in the time of harvest, or any time to work at any other work," provided he took with him "a certificate from the minister of the parish and one of the parish officers, that he or they have a dwelling house or place in which he or they inhabit, and have left wife and children, or some of them, there (or otherwise, as the condition of the persons shall require), and is declared an inhabitant or inhabitants there." In such case, if the person did not return to his parish when his work was finished, or if he fell sick, it was not "counted a settlement," and he was therefore removable, and, wilfully refusing, was punishable as a vagabond by being sent to the house of correction, or to a public workhouse, provision for which and for corporate bodies in relation to the poor in London and Westminster, and places within the so-called bills of mortality, was made at the same time. Funds raised for the relief of the poor in the city of London were, however, previously in the hands of a corporate body for that purpose.

The same statute, reciting that "the inhabitants of the counties of Lancashire, Cheshire, Derbyshire, Yorkshire, Northumberland, the bishopric of Durham, Cumberland, and Westmoreland, and many other counties in England and Wales, by reason of the largeness of the parishes within the same," could not reap the benefit of the Act

43 Eliz., extended the powers of the Act to townships and villages within these counties.

Power was given to justices at quarter sessions, to transport rogues, vagabonds, and sturdy beggars, in some cases with the approval of the privy council, or without such approval, if convicted and adjudged to be incorrigible, to any of the English plantations beyond the seas, "there to be disposed in the usual way of servants for a term not exceeding seven years."

This Act, which, except as to the corporate bodies before mentioned, was limited to three years' duration, was continued by various Acts, and made perpetual in the reign of Anne. One of the Acts continuing the former provisions, and containing some minute provisions affecting settlements, affords strong evidence of want of care of the funds, and even of the frauds practised by parochial officers. Many inconveniences arose "by reason of the unlimited power of the churchwardens and overseers of the poor, who do frequently upon frivolous pretences (but chiefly for their own private end-) give relief to what persons and number they think fit; and such persons, being entered into the collection bill, do become after that a great charge to the parish, notwithstanding the occasion or pretence of their receiving collection oftentimes ceases, by which means the rates for the poor are daily increased." This grievance was sought to be remedied by means of a register with names and dates, to be examined by the vestry, and those only to be relieved who were allowed by a justice, except in certain urgent cases. The Act mentions more direct frauds. "Many churchwardens and overseers of the poor, and other persons intrusted to receive collections for the poor and other public moneys relating to the churches and parishes whereunto they do belong, do often mispend the said moneys and take the same to their own use, to the great prejudice of such parishes, and the poor and other inhabitants thereof," owing to the law by which persons in any way interested in the funds, as parishioners, although the only persons who could prove the facts, could not give evidence on the trial of actions against the parish officers to recover the mispent money; and therefore parishioners, excepting almsmen, were rendered competent witnesses in such actions (3 Will. 4 Mary c. 11).

**Restraint on removal of the poor.** The injurious effects of the restraint placed on the free removal of the labouring classes is evinced by a statute towards the close of the 17th century. To make this intelligible it is necessary to say that by the statute 1 James II. c. 17 (one of the Acts continuing the Act of Charles II.) it was enacted that, as poor persons "at their first coming to a parish do commonly conceal themselves," the forty days continuance in a parish intended by the Act of Charles to make a settlement were to be accounted from the time of the person's delivering a notice in writing of the house of abode and number of the family to the parish officer. Hence persons coming to work under a certificate, on its production, were removed back again, lest they gained a settlement at the end of forty days. The statute now to be noticed recited that, "forasmuch as many poor persons chargeable to the parish, township, or place where they live, merely for want of work, would, in any other place where sufficient employment is to be had, maintain themselves and families without being burthensome to any parish, township, or place, but not being able to give such security as will or may be expected and required upon their coming to settle themselves in any other place, and the certificates that have been usually given in such cases having been oftentimes construed into a notice in handwriting, they are for the most part confined to live in their own parishes, townships, or places, and not permitted to inhabit elsewhere, though

their labour is wanted in many other places, where the increase of manufactures would employ more hands." This mischievous result of previous legislation was sought to be avoided by a certificate of acknowledgment of settlement, and then and not before, on becoming chargeable to another parish, the certificated person could be sent back to the parish whence it was brought (8 & 9 Will. III. c. 30). This provision led to additional legislation, complicating the law of settlement. It was not until towards the close of the 18th century that an important inroad on the law relating to the removal of the poor was made by requiring actual chargeability before removal to their place of settlement (35 Geo. III. c. 101); and at the same time justices were empowered to suspend removal in the case of sickness.

By the statute of William III. (8 & 9 Will. III. c. 30), "to the end that the money raised only for the relief of such as are as well impotent as poor may not be misapplied and consumed by the idle, sturdy, and disorderly beggars," persons receiving parochial relief and their wives and children were required (under the punishment for refusal of imprisonment and whipping, or of having the reliefs abridged or withdrawn) to wear a badge on the shoulder of the right sleeve—that is to say, a large "P" together with the first letter of the name of the parish or place, cut in red or blue cloth; and a penalty was imposed on churchwardens and overseers relieving poor persons not wearing such badge. The provision (a revival of a much earlier law) continued down to 1810, when it was abolished.

In 1744 provision was made reviving rather than introducing a system of magisterial "passes" for passing persons apprehended as rogues and vagabonds to their place of settlement (17 Geo. II. c. 5). Great abuses in conveying persons by passes, attributed to the neglect of this Act, led to its amendment nearly half a century later. Although these statutes fell into disuse they were not finally repealed until after the introduction of the present poor-law system.

In 1722 the system of farming the poor was introduced. By 9 Geo. I. c. 7, "for the greater ease of parishes in the relief of the poor," parish officers with the consent of the parishioners or inhabitants in vestry were authorized to purchase or hire houses, "and to contract with any person or persons for the lodging, keeping, maintaining, and employing any or all such poor in their respective parishes, townships, or places, as shall desire to receive relief or collection from this same parish, and there to keep, maintain, and employ all such poor persons, and take the benefit of the work, labour, and service of any such poor person or persons who shall be kept or maintained in any such house or houses, for the better maintenance and relief of such poor persons who shall be there kept or maintained." Any poor persons refusing to be so lodged were not to be entitled to relief. Small parishes could unite or contract with another parish for the maintenance of the poor.

A few years sufficed to develop the injurious effects of this mode of dealing with the poor, and the accumulated evils of the working of the poor laws led, in 1783, to the passing of the statute 22 Geo. III. c. 83, known as "Gilbert's Act," the principle of which was extensively adopted in subsequent legislation. The Act significantly recited that, notwithstanding the many laws now in being for the relief and employment of the poor, and the great sums of money raised for those persons, their sufferings and distresses are nevertheless very grievous, and by the incapacity, negligence, or misconduct of overseers, the money raised for the relief of the poor is frequently misapplied, and sometimes expended in defraying the charges of litigations about settlements indiscreetly and inadvisably carried on, and also recited the provisions of

the 9 Geo. I. c. 7, relating to contracts for the maintenance of the poor, and that such provisions, from the want of proper regulations and management in the poorhouses or workhouses that have been purchased or hired under the authority of the said Act and for want of due inspection and control over the persons who have engaged in those contracts, have not had the desired effect, "but the poor in many places, instead of finding protection and relief, have been much oppressed thereby." "For the remedy of these grievances and inconveniences, and in order to make better and more effectual provision for the relief and employment of the poor, and to introduce a prudent economy in the expenditure of the parish money," much legislative machinery was introduced, which, although not compulsory, was very extensively adopted, and with many amendments remained on the statute book long after the Poor Law Amendment Act of 1834. Although the Act has now disappeared, having been expressly repealed (as it was by implication previously) in 1871, Gilbert's Act is memorable as having first introduced the representation of the poor by guardians, although not by the present system of election. The Act repealed 9 Geo. I. c. 7, as regarded the farming of the poor where Gilbert's Act was adopted, but agreements for the diet and clothing and work of poor in poorhouses, subsequently termed "houses of industry," were expressly sanctioned. The limits of this article do not admit even of an analysis of this important statute. In many respects a double system of administration sprang up in parishes, single or united, adopting Gilbert's Act, and in parishes not under that Act. In both, the conflict between the administration of relief in and out of the poorhouse arose, and continued from the time of the establishment of places of work whether termed workhouses, poorhouses, or houses of industry, and whether under special local or under general Acts.

house

In 1795 the 36 Geo. III. c. 23, reciting that a provision of the 9 Geo. I. c. 7, prohibiting relief to persons refusing to go into poorhouses, "has been found to have been and to be inconvenient and oppressive, inasmuch as it often prevents an industrious poor person from receiving such occasional relief as is best suited to the peculiar case of such poor person, and inasmuch as in certain cases it holds out conditions of relief injurious to the comfort and domestic situation and happiness of such poor persons," gave power to the overseers, with the approbation of the parishioners in vestry or of a justice of the peace, to distribute and pay collection and relief to industrious poor persons at their homes under certain circumstances of temporary illness or distress, and in certain cases respecting such poor persons or their families, or respecting the situation, health, or condition of any poorhouse, in any place wherein houses shall have been hired or built and a contract made with any person for lodging, maintaining, and employing the poor, although the poor persons refused to be so lodged and maintained. Justices had besides a "just and proper discretion" for special cause stated in order to order relief for a time not exceeding a month. The Act, however, did not extend to places where houses of industry or other places were provided under Gilbert's Act or under any special Act.

The evils arising from farming the poor under the 9 Geo. I. c. 7 nevertheless continued in places not adopting Gilbert's Act. Contractors were often non-resident and not of sufficient responsibility to insure performance of their undertaking. In 1805 these special defects were sought to be met by requiring residence, sureties, and the approval of the contract by two justices (45 Geo. III. c. 12). But these remedies did not touch the whole extent of the evil of neglect of the poor. The laws for regulating

workhouses and poorhouses were found deficient and ineffectual, especially when the poor in such houses were "afflicted with contagious or infectious diseases, in which cases particular attention to their lodging, diet, clothing, bedding, and medicine is requisite." A statute passed in 1790 (30 Geo. III. c. 49) enabled justices, or medical men authorized by them or the officiating clergyman of the parish, to visit workhouses, and on finding cause for complaint to certify to the quarter sessions, and thereupon the court was authorized to make orders for removing any cause of complaint; and, moreover, without waiting for this dilatory process, if on the visitation any of the poor were found afflicted with any contagious or infectious disease, or in want of immediate medical or other assistance, or of sufficient food, or requiring separation or removal, justices of the division were empowered to make an order for immediate relief according to the nature of the application. There can be no doubt that the legislation of five years later already noticed (36 Geo. III. c. 23) had reference to cases of this kind as well as to the hardships inherent in the rigid application of the practice of confining relief to the workhouse.

In 1819 an Act (59 Geo. III. c. 12) was passed, the result of the report of a committee appointed two years before, containing a variety of provisions relating to the poor, vestries, empowering the establishment of select vestries "for the concerns of the poor" and regulating their proceedings. Where these were established overseers were prohibited from giving relief other than that ordered by the vestries, except temporary relief in cases of sudden emergency or urgent necessity. Justices had the power, as under earlier provisions, to order temporary relief in such cases, but they were prohibited from ordering relief in parishes where select vestries were established or in which the relief of the poor was under the management of guardians, governors, or directors, unless relief had been refused by such bodies.

An amelioration of the harsher features of the law, and Vagrant the separation of that branch of it relating to vagrancy, are found in the legislation of the 18th and early part of the 19th century. In early times, as has been pointed out, legislation affecting labour and vagrancy was blended. Very gradually labour was left to run a freer course. Provisions as to vagrancy and mendicity, including stringent laws in relation to constructive "sturdy beggars," "rogues," and "vagabonds," still formed a prominent feature of poor-law legislation.

In 1713 an Act was passed for reducing the laws relating to rogues, vagabonds, sturdy beggars, and vagrants into one Act, and for more effectually punishing them and sending them to their homes, the manner of conveying them including whipping in every county through which they passed (12 Anne, st. 2, c. 23). This Act was in turn repealed in 1740; and the substituted Consolidation Act (13 Geo. II. c. 24), embracing a variety of provisions, made a distinction between idle and disorderly persons, rogues and vagabonds, and incorrigible rogues. Four years later a statute reciting that "the number of rogues, vagabonds, beggars, and other idle and disorderly persons daily increases, to the great scandal, loss, and annoyance of the kingdom," deals with a great variety of offences, continuing the rough classification already mentioned, and including among "idle and disorderly persons" punishable with hard labour in the house of correction "all persons who shall run away and leave their wives or children to the parish" and "all persons who shall unlawfully return to the parish or place from whence they have been legally removed by order of justices, without bringing a certificate," and also "all persons who, not having wherewith to maintain themselves, live idly without employment and refuse to work for the usual and common wages given to

other labourers on the like work, in the parishes or places where they then are," and also all persons begging alms (17 Geo. II. c. 5).

The laws relating to idle and disorderly persons, rogues and vagabonds, incorrigible rogues, and other vagrants in England were again consolidated and amended in 1822 (3 Geo. IV. c. 40), but the Act being temporary and requiring amendment, was superseded two years later by the present Act, 5 Geo. IV. c. 83, commonly spoken of as the Vagrant Act, which with some additions and amendments includes the law relating to mendicancy and some provisions concerning persons deserting or neglecting to support their families. Mendicancy in the popular sense is now considered as appertaining to police rather than to poor laws. It must suffice here to note the change from former inhuman laws denoted by the fact that corporal punishment is confined by the Vagrant Act to the permissive infliction of whipping on male persons imprisoned as incorrigible rogues.

regular-  
ties of  
poor law  
officers.

The misdoings of the "vagrant train," so often paraded by statute and so severely treated in former times, seem to have been trifling compared with the iniquities of some of those engaged in the administration of poor-law relief. In 1769 it was found necessary to prevent churchwardens and overseers from wilfully and knowingly making payments to or for the use of the poor in base and counterfeit money (9 Geo. III. c. 37). For this heinous offence a penalty limited to twenty shillings was imposed. The curious may compare this mild punishment with that inflicted on a wanderer from his home: for as recently as 1816 it was thought right to declare that it should not be lawful for any governor, guardian, or master of any house of industry or workhouse on any pretence to chain or confine by chains or manacles any poor person of sane mind, a provision significant of what passed within the walls by its prohibition as well as by the limitation.

Such were the most salient features of the legislation respecting the relief of the poor previous to the reform of parliament itself in 1832.

Evils and  
remedies  
remained.

It had long been seen that there was something wrong which legislation had failed to set right. Sir Matthew Hale framed a scheme which was written soon after the middle of the 17th century, although not printed until after his death. The chief feature of his plan was "that the justices of the peace at the quarter sessions do set out and distribute the parishes in their several counties into several divisions, in each of which there may be a workhouse for the common use of the respective divisions wherein they are respectively placed,—to wit, one, two, three, four, five, or six parishes to a workhouse according to the greatness or smallness and accommodation of the several parishes," and that providing "a stock" for work in and out of the workhouses should be made compulsory. His views are thus stated:—

"At this day, it seems to me, that the English nation is more deficient in their present provision for the poor than any other Christian state. . . . In some other countries a beggar is a rare sight. Those that are unable to maintain themselves by age or impotency are relieved. And those that are able to supply their wants by their labour are furnished with employments suitable to their condition. And by this means there is not only a good and orderly education and a decent face of the public, but the more populous the state or country is the richer and the more wealthy it is. But with us in England, for want of a due regulation of things, the more populous we are the poorer we are: so that the strength and wealth of a kingdom consists not in the number and the poor; and, which is yet worse, poor families which daily multiply in the kingdom, for want of a due order for their employment in an honest course of life, whereby they may gain subsistence for them and their children, do unavoidably bring up their children either in a trade of begging or stealing, or such other idle course, which again they propagate over to their children: and so there is a successive multiplication of hurtful or at least

unprofitable people, neither capable of discipline nor beneficial employment.

He further remarks that the continuance of the evils he depicted "must in time prodigiously increase and overgrow the whole face of the kingdom, and eat out the heart of it." In lamenting the want of an industrious education he observes that "a man that has been bred up in the trade of begging will never, unless compelled, fall to industry; and, on the other side, it is a wonderful necessity indeed that shall bring one bred up in civility or industry to beg." Almost all subsequent schemes looked up to Hale as their model; but all either were not accepted or did not succeed, although in some of the legislation of the 18th century imperfect attempts seem to have been made in this direction. Among other schemes Sir Josiah Child, in the reign of Charles II., who speaks of the poor in England having always been "in a most sad and wretched condition," proposed to abolish all settlements and receive every poor person that applied to incorporated societies or "fathers of the poor." John Cary, writing about 1700, having for the burden of his tract, and the cure of existing evils, to "provide work for those who are willing, and force them to work that are able," makes some pithy remarks.

"He that walks the streets of London, and observes the fatigues used by the beggars to make themselves seem objects of charity, must conclude that they take more pains than an honest man doth at his trade, and yet seem not to get bread to eat. Beggary is now become an art or mystery, to which children are brought up from their cradles. Anything that may move compassion is made a livelihood, a sore leg or arm, or for want thereof a pretended one. The tricks and devices I have observed to be used by those people have often made me think that those parts, if better employed, might be made useful to the nation." "Licences for almshouses were at first granted for good ends, not to draw men aside from their labour by games and sports, but to support and refresh them under it; whereas almshouses are now encouraged to promote the income of excise,—not considering withal that the labour of each man, if well employed, whilst he sits in an almshouse, would be worth much more to the nation than the excise he pays." "Our laws to set the poor at work are short and defective, tending rather to maintain them so than to give them to a better way of living. 'Tis true, these laws design well; but, consisting only in generals, and not reducing things to practicable methods, they fall short of answering their ends, and thereby render the poor more bold when they know the parish officers are bound either to provide them work or to give them maintenance."

In 1735 Mr Hay, a member of the House of Commons, introduced a bill, which, however, was not passed, appointing guardians of a district, chosen by divers occupiers out of a list of persons qualified by estate in land, with power to purchase land, and build and furnish workhouses, and provide stock to set the poor to work, to be paid for by rate,—"every person to be deemed to be legally settled where he continued a year without being chargeable, and if he gained no such settlement then at the place of his birth, and if not born in the kingdom then where he should happen to want relief,"—parochial settlement to be abolished, and a county settlement substituted.

In 1753 bills were introduced into parliament by the earl of Hillsborough and Sir Richard Lloyd, but neither was passed. Lord Hillsborough proposed to repeal all existing Acts, re-enacting much, but getting rid of the notion of settlements and removals, and establishing a county board as governors of the poor with officers to carry out their bye-laws, and hospitals for the impotent and the aged and their children, and for no other kind of poor. In the same year Fielding printed *A Proposal for making an effectual Provision for the Poor, for amending their Morals, and for rendering them useful Members of the Society*. His plan embraced county houses of correction, and places of work, maintenance, and punishment, including a "fasting room." It may be regarded as supplementary to schemes of the same period. Although all that fell from this author is worthy of attention, his plan cannot

be examined closely here; but what he says of the state of things at the period, evidently the result of his daily observations as a magistrate and inhabitant of Westminster, is too striking to be passed over.

"That the poor are a very great burden and even a nuisance to the kingdom, that the laws for relieving their distress and restraining their vices have not answered their purposes, and that they are at present very ill provided for and much worse governed are truths which every man will acknowledge. Every person who hath any property must feel the weight of that tax which is levied for the use of the poor; and every person who hath any understanding must see how absurdly it is applied. So very useless, indeed, is the heavy tax, and so wretched its disposition, that it is a question whether the poor or rich are actually more dissatisfied; since the plunder of the one serves so little to the real advantage of the other. For while a million yearly is raised among the rich many of the poor are starved; many more languish in want and misery; of the rest, numbers are found begging or pilfering in the streets to-day, and to-morrow are locked up in jails and bridewells. If we were to make a progress through the outskirts of the metropolis, and look into the habitations of the poor, we should there behold such pictures of human misery as must move the compassion of every heart that deserves the name of human. What indeed must be his composition who could see whole families in want of every necessary of life, oppressed with hunger, cold, nakedness, and filth, and with diseases the certain consequence of all these! The sufferings indeed of the poor are less known than their misdeeds; and therefore we are less apt to pity them. They starve, and freeze, and rot among themselves; but they beg, and steal, and rob among their betters. There is not a parish in the liberty of Westminster which doth not swarm all day with beggars and all night with thieves."

The observations of Dr Burn, a name known to every one who has considered the poor laws, whether as legislator, magistrate, or lawyer, followed in 1764. Although the suggestions and observations in his *History of the Poor Laws* are worthy of the highest attention to any one entering into an historical retrospect, it must suffice here to say that the result of his experience and knowledge was that the laws then in force should "stand as to the main" but be rectified on two points—begging, and the management of the poor by overseers. Dr Burn says:—

"But how shall begging be restrained? which by a kind of prescriptive claim hath so long been accustomed to triumph above the laws. All sorts of severities, it appears, have been enacted against vagrants; and yet they wander still. Nevertheless, one would hope the disease is not past all remedy. If it is, let us cease the unequal contention, and submissively give up our fortunes to the next that comes with a pass, and tells us a justice of the peace hath so ordered it; but let beggars and vagrants be doing. There is one infallible way to put an end to all this, and the easiest in the world, which consists merely in a non-feasance. Give them nothing. If none were to give, none would beg; and the whole mystery and craft would be at an end in a fortnight. Let the laws continue if you please to apprehend and punish the mendicants; but let something also be done effectually against those who encourage them. If the principal is punished, it is not reasonable the accessory should go free. In order to which, let all who relieve a common beggar be subject to a penalty."

As to the other "fundamental defect," as Dr Burn styles the leaving the management of the poor to overseers, the position of overseers and their action are so admirably painted, and the description so applicable to the mode of administration down to the reform of 1834, that the observations, written in a happy strain of irony, must be inserted.

"As to overseers of the poor, it is true the law provides that they shall be substantial householders. But many a man may be a substantial householder who is not fit to be an overseer of the poor. And in fact the office goes by rotation from one householder to another,—some perhaps tenants at rack rent, whose lease expires the next year, others ignorant and unexperienced, others not willing to charge themselves to disoblige their neighbours; and all of them wanting to get over the office with as little trouble to themselves as possible; and if any, wiser than the rest, projects anything for the common good his office expires at the end of the year and his labour is frustrated, and in practice the office of an overseer of the poor seems to be understood to be this:—To keep an extraordinary look-out to prevent persons coming to inhabit without certificates, and to fly to the justices to remove them; and if a man brings a certificate then to caution all the inhabitants not to

let him a farm of £10 a year, and to take care to keep him out of all parish offices; to warn them, if they will hire servants, to hire them half-yearly or by the month, by the week or by the day, rather than by any way that shall give them a settlement, or if they do hire them for a year then to endeavour to pick a quarrel with them before the year's end, and so to get rid of them. To maintain their poor as cheap as possibly they can; at all events not to lay out two-pence in prospect of any future good, but only to serve the present necessity; to bargain with some sturdy person to take them by the lump, who yet is not intended to take them, but to hang over them in terror if they shall complain to the justices for want of maintenance. To send others out into the country a begging (for why cannot they go as well as others they will mention, who are less able in body?) and the feeble they are the more profitable will be their peregrination. To bind out poor children apprentices, no matter to whom or to what trade, but to take especial care that the master live in another parish. To move heaven and earth if any dispute happens about a settlement, and in that particular to invert the general rule, and stick at no expense. To pull down cottages. To drive out as many inhabitants and admit as few as possibly they can; that is, to depopulate the parish in order to lessen the poor rate. To be generous, indeed, sometimes, in giving a portion with the mother of a bastard child to the reputed father, on the condition that he will marry her; or with a poor widow (for why should she be deprived of the comforts of matrimony?)—always provided that the husband is settled elsewhere. Or if a poor man with a large family appears to be industrious they will charitably assist him in taking a farm in some neighbouring parish, and give him £10 to pay his first year's rent with; and if any of their poor has a mercantile genius they will purchase for him a box, with pins, needles, laces, buckles, and such like wares, and send him abroad in the quality of a petty chapman, with the profits whereof, and a moderate knack of stealing, he can decently support himself, and educate his children in the same industrious way. But to see that the poor shall resort to church, and bring their children there to be instructed; to contract with a master that he shall procure his apprentice at proper times to be taught to read and write; to provide a stock of materials to set the poor on work, to see the aged and impotent comfortably sustained, the sick healed, and all of them clothed with neatness and decency,—these and such like it is to be feared are not so generally regarded as the laws intended and the necessity of the case requires."

Dr Burn's remedy was not to abolish overseers altogether, but that, while they or a permanent overseer should collect the rate, a general superintendent over a certain number of parishes should be appointed by the justices at sessions, and the disposal of the rate directed accordingly.

How far the criticism and suggestions made, from those of Sir Matthew Hale downwards from time to time, influenced the legislation already indicated of the 18th century and the early part of the 19th, it is impracticable to discover. One thing is certain, that evils grew apace: ratepayers on the one hand, the poor on the other, political economists and philanthropists, magistrates and jurists, and observers of every kind were dissatisfied. For the general state of the poor in the beginning of the 19th century as presented to the accurately observant eye and ear of our English Juvenal, we glean more from his *Borough* than from a pile of statistics. Of the poor who were chargeable to the parish Crabbe says:—

"To the most we give  
A weekly dole, and at their homes they live."

Of the workhouse or house of industry, "the pauper palace which they hate to see," he speaks mournfully. In prose he wrote of the poor who "must be considered in every place as a large and interesting portion of its inhabitants," condemning the workhouse system, alike the pauper palace and the house rented for the poor,—the

"House that holds the parish poor,  
Whose walls of mud scarce bear the broken door."

A closer examination of the system of maintaining the poor than could be obtained by casual visitors, or even constant residents having no special duty to examine or inquire, showed, in full accord with the public criticism already examined, and in spite of it, that the fund which the famous statute of Elizabeth directed to be employed in setting to work children and persons capable of labour, but using no daily trade, and in the necessary relief of

Enumeration and classification of evils.

the impotent, was by degrees applied to purposes opposed to the letter and still more to the spirit of that law, and destructive to the morals of the most numerous class and to the welfare of all. The great source of abuse was the relief afforded out of the workhouse to able-bodied persons,—a class never intended by the legislation as fit objects. The description of relief was also very objectionable. Its most usual form was that of relieving the applicants either wholly or partially from the expense of obtaining house room. Partial relief from that expense was given or professed to be given by exempting the occupants of a cottage or apartment from the payment of rates on the ground of poverty, and in a great number of cases by paying the rent out of the parish fund. Relief afforded in money to the able-bodied on their own account or on that of their families was still more prevalent. This was generally effected by one of the five following expedients:—(1) relief without labour, (2) the allowance system, (3) the roundsmen system, (4) parish employment, (5) the labour-rate system. (1) The relief without labour was by the parish giving to those who were or who professed to be without employment a daily or weekly sum, without requiring from the applicant any labour. (2) "Allowance" sometimes comprehended all parochial relief afforded to those who were employed by individuals at the average rate of wages of the district, and was sometimes confined to the relief which a person so employed obtained on account of his children, in that case any relief obtained on his own account being termed "payment of wages out of rates." In some places allowance was given only occasionally or to meet occasional wants, for instance, to buy clothing or food or to pay the rent of a cottage or apartment. Sometimes the income of the poor was regulated by the name of "scales"—giving in money the price of so many loaves of bread or of a specific measure of flour, according to the number of the family. (3) The roundsman (or, as it was sometimes termed, the billet, or ticket, or item) system was the parish paying the occupiers of property to employ the applicants for relief at a rate of wages fixed by the parish, and depending not on the services, but on the wants of the applicants, the employer being repaid out of the poor rate all that he advanced in wages beyond a certain sum. According to this plan the parish in general made some agreement with a farmer to sell to him the labour of one or more paupers at a certain price, paying to the pauper out of the parish funds the difference between that price and the allowance which the scale, according to the price of bread and the number of his family, awarded to him. It received the local name of billet or ticket system from the ticket signed by the overseer which the pauper in general carried to the farmer as a warrant for his being employed, and afterwards took back to the overseer, signed by the farmer, as a proof that he had fulfilled the conditions of relief. In other cases the parish contracted with a person to have some work performed for him by the paupers, at a given price, the parish paying the paupers. In many places the roundsman system was carried out by means of an auction, all the unemployed men being put up to sale periodically, sometimes monthly or weekly, at prices varying according to the time of year, the old and infirm selling for less than the able-bodied. (4) As for parish employment, although work is made by the statute of Elizabeth a condition precedent to relief otherwise than in the case of the impotent, and it is a duty of the parish officers to provide it, payment by them for work was the most unusual form in which relief was administered. Scarcely more than one-twentieth part of the sum yearly expended for the relief of the poor at the period immediately preceding the inquiry that led to the amendment of the law in 1834 was paid for work, including work on the roads and in the workhouses.

This was easily accounted for "by many causes, including the trouble and difficulty attendant upon superintendence on the part of parish officers." (5) An agreement among the ratepayers that each of them should employ and pay out of his own money a certain number of the labourers settled in the parish, in proportion not to his real demand for labour but to his rental or to his contribution to the rates, or to the number of horses that he kept for tillage, or to the number of acres that he occupied, or to some other fixed standard, has been denominated the labour-rate system. This system was generally enforced by an additional voluntary rate on those who did not employ their full proportion.

As illustrating the difficulties attendant upon providing for the poor, a temporary Act passed in 1832, which has disappeared from the statute book (as founded on vicious notions), may be noticed, applying to parishes where the poor rates exceeded 5d. in the pound. It recited that, notwithstanding the many laws in force for the relief and employment of the poor, many able-bodied labourers are frequently entirely destitute of work or unprofitably employed, and in many instances receive insufficient allowance for their support from the poor rates, and "the mode of providing employment for the poor which may be expedient in some parishes may be inexpedient in others, and it may therefore be desirable to extend the powers of parish vestries in order that such a course may be pursued as may be best adapted to the peculiar circumstances of each parish," and enabled vestries (without interfering with Gilbert's Act), with the approval of justices at petty sessions, to make special agreements solely for the purpose of employing or relieving the poor of the parish.

The following table exhibits the growth of the poor rate from the middle of the last century to a date immediately preceding the reforms effected in 1834:—

Years.	Estimated Population of England and Wales.	Expended on the Relief of the Poor.	Per Head of the Population.
		£	s. d.
1750	6,467,000	682,000	2 2
1760	6,733,000	935,000	3 0
1770	7,423,000	1,206,000	3 6
1780	7,353,000	1,774,000	4 5
1790	8,673,000	2,567,000	5 11
1800	9,140,000	3,851,000	8 5
1810	10,370,000	5,467,000	10 3
1815	11,762,000	7,590,000	13 4
1820	12,046,000	7,325,000	12 2
1830	13,624,000	6,822,000	2 2
1832	14,372,000	7,026,000	2 9

It will be observed that subsequent to 1818 there was an apparent diminution in the whole sum expended for the relief of the poor, making a difference of between 11 and 12 per cent.; but the decline in the prices of the necessaries of life (wheat alone had fallen considerably,—more than one-half in one of the intermediate years) was more than equivalent to the difference.

The conviction, arising principally from the increase of the poor rates, that a change was necessary either in the poor law as it then existed or in the mode of its administration led to the issuing of a commission in 1832 "to make diligent and full inquiry into the practical operation of the laws for the relief of the poor in England and Wales, and into the manner in which those laws were administered, and to report their opinion as to what beneficial alterations could be made." The result of this inquiry was laid before parliament in 1834. The commissioners reported "fully on the great abuse of the legislative provision for the poor as directed to be employed by the statute of Elizabeth," finding "that the great source of abuse was the out-door relief afforded to the able-bodied on their own

poor-Law account or on that of their families, given either in kind or in money." They also reported that "great maladministration existed in the workhouses." To remedy the evils they proposed considerable alterations in the law, and the principal portion of their suggestions was embodied in the Poor-Law Amendment Act, 1834 (4 & 5 Will. IV. c. 76).

The Act was based on the principle that no one should be suffered to perish through the want of what is necessary for sustaining life, but at the same time that if supported at the expense of the public he must be content to receive such support on the terms most consistent with the public welfare; and the objects of the Act were first to raise the labouring classes, that is to say, the bulk of the community, from the idleness, improvidence, and degradation into which the maladministration of the laws for their relief had thrown them, and, secondly, to immediately arrest the progress and ultimately to diminish the amount of the pressure on the owners of lands and houses.

Under the Act three commissioners were appointed (originally for five years, but subsequently continued from time to time) styled "the Poor-Law Commissioners for England and Wales," sitting as a board, and appointing assistant commissioners and other officers. The administration of relief according to the existing laws was subject to their direction and control, and to their orders and regulations for the government of workhouses and the guidance and control of guardians and vestries and the keeping and allowing of accounts and contracts, without interfering with ordinary relief in individual cases.

The favourable state of the country at the time presenting many facilities for the introduction of the law, which it was important to render available with as little delay as possible, the whole of England and Wales was divided into twenty-one districts, to each of which an assistant commissioner was appointed. The commissioners under their powers (gradually put into operation—a circumstance which beneficially affected legislation of the period, as, for example, the commutation of tithes and the introduction of police) formed poor-law unions by uniting parishes for general administration, and building workhouses, guardians elected by the ratepayers (or *ex officio*) having the general government and administration of relief. The expense was apportioned to each parish on settled principles and rules, with power, however, to treat the united parishes as one for certain purposes. Outdoor relief might be given, on the order of two justices, to poor persons wholly unable to work from old age or infirmity. No rule appears to have been more fully sanctioned by practical results as of an advantageous nature than that under which the country was by degrees parcelled out into unions. In parishes no adequate power existed for carrying into effect the rules and regulations of the amended system. No principle of classification could be adopted within the workhouses, and the law was liable to be thwarted in its most material objects by petty interests of a local and personal character. With the aid of boards of guardians and their subordinate officers these interests were neutralized, and the law was rendered uniform in its operation. The economical advantages derived from acting on an enlarged scale are self-evident. Waste unavoidably takes place when the purchase of supplies for a single parish forms a separate transaction.

The second report of the commissioners showed that of one hundred and ten unions which had been in operation more than a year, the saving in forty-three of the largest was 46 per cent.; in twenty-four of the smallest unions the rate of saving was not more than 29 per cent.; and in twenty-six unions of intermediate size a saving of 42 per cent. was effected. Even in many parishes not then included in a union the wide promulgation of the principles of the amending Act gave an impulse to improve-

ment in the administration of the poor laws, which was attended by a marked reduction in the expenditure.

The total amount of money expended in the relief of the poor in England and Wales during the twelve years prior to the passing of the Poor-Law Amendment Act (1823 to 1834) amounted to upwards of £76,096,000, and during the twelve subsequent years to less than £57,247,000. As the commissioners early remarked—

"It could not be expected that an Act which so materially disturbed the distribution of as large a sum of money as £7,000,000 per annum, which of necessity changed the source from which a large portion of the inhabitants of the country derived their customary means of subsistence, and which in so doing opposed itself not only to the interests, the prejudices, and the fears of a large portion of the population, but pressed hardly on the sincere though mistaken notions of charity which were established in the hearts of others, could possibly be carried into effect without difficulty and resistance.

The obstacles which the Act had to contend with in the metropolis chiefly arose from the confusion and perplexity of jurisdiction which existed in the one hundred and seventy parishes comprised within the city of London and the metropolitan district, some of these containing governing bodies of their own; in some the parish business was professedly managed by open vestries, in others by select vestries, and in addition to these there were elective vestries, under Sturges Bourne's Act, Sir John Hobhouse's Act, and other Acts; and the majority of the large parishes were managed under local Acts by boards of directors, governors, and trustees. These governing bodies executed a great variety of functions besides regulating the management of the poor. The power, patronage, and the indirect advantages which arose from the administration of the local funds were so great that much opposition took place when it was proposed to interfere by constituting a board to be annually chosen and freely elected by the ratepayers, on which the duty of regulating the expenditure for the relief of the poor was to depend. The general management of the poor was, however, on a somewhat better footing in London than in the country.

Some opposition was experienced to the introduction of the full benefits of the Act into the unions incorporated under Gilbert's Act, many provisions of which conflicted with the new system. On the early dissolution of seventeen of those incorporations by the commissioners under their powers, it was found, however, that the rates were sensibly diminished. Much resistance of a general nature was encountered. Not only was the economical working of the new principles of management disputed, but a strong feeling was aroused against what was thought to be the inhumanity of the rigorous rules to which paupers had to submit in workhouses. While many proofs existed of the necessity for the introduction of a new system—such as that, while wheat was rotting in pauperized and as yet unreformed districts of the south of England for want of reapers at 21s. and 24s. an acre, at the very same time able-bodied healthy men were lying under the hedges in another part of the same county with a parish allowance of 3s. a week—on the other hand, it was felt as a grievance that old couples were refused relief at their own houses, and that if they entered the workhouse the sexes were separated. Throughout the country the reproachful name of "Bastille" was attached to the workhouse, and this is in many districts still retained, though no longer as an intended censure. In part of Devonshire prejudice was carried to the extent of a rumour leading poor persons to believe that the bread distributed by the relieving officers was mixed with poisonous ingredients.

Both Houses of Parliament were inundated for years with petitions against the new system; meetings were held at which inflammatory language was used; and in

some instances riotous proceedings marked the opposition. It was remarked that the acts of violence were in the most pauperized districts, which had been conspicuous for the maladministration of the poor rates. The work, however, went forward, although three parliamentary committees (one of the Lords and two of the Commons) instituted a searching and severe scrutiny before the organization of the system was completed. Notwithstanding adverse circumstances, including stagnation of trade, cold weather, and an epidemic of great severity, by the end of 1837 nearly the whole of England had been formed into unions; the benefits of the new system were gradually recognized, and a poor law was introduced into Ireland (see IRELAND). As to poor-law administration in Scotland see SCOTLAND.

**Medical attendance.** The reform of the poor laws affected a variety of persons besides paupers and ratepayers. No question was more widely discussed than that of medical attendance on the sick poor. The outdoor relief of the sick was usually effected by a contract with a surgeon, which, however, in general only included those who were parishioners. When non-parishioners became chargeable from illness, an order for their removal to their place of settlement was obtained, which was suspended until they could perform the journey; in the meantime they were attended by the local surgeon, but at the expense of the parish to which they belonged. The poor-law commissioners in their report of 1834 stated that on the whole medical attendance seemed in general to be adequately supplied and economically, considering only the price and the amount of attendance. Great good was effected by the establishment of dispensaries promoted by Mr Smith of Southam to enable the labouring classes to defray, from their own resources, the expense of medical treatment. While stating that the country was much indebted to him for his exertions, the commissioners were not prepared to suggest any legislative measures for their encouragement; but dispensaries have been recently applied to the relief of the poor in the metropolis. The medical and surgical association (now the British Medical Association), of which Sir Charles Hastings was president, took up the subject, and a committee, over which Dr Davis (of Presteign) presided, made an inquiry and report,—by no means in hostility to, but in full accord with, the chiefs of the new poor-law administration. The present mode of giving medical relief is noticed below.

**Local government board.** After an intermediate transfer in 1847 of the powers of the poor-law commissioners, and the constitution of a fresh board styled "commissioners for administering the laws for relief of the poor in England," it was found expedient to concentrate in one department of the Government the supervision of the laws relating to the public health, the relief of the poor, and local government; and this concentration was in 1871 carried out by the establishment (by Act of Parliament 34 & 35 Vict. c. 70) of the Local Government Board.

In the subsequent part of this article the governing board, whether the original poor-law commissioners or commissioners for administering the laws for relief of the poor, or the present local government board, is spoken of as the central board, as the orders at present in force are of various dates, and chiefly issued before the existence of the present local government board.

By numerous Acts of Parliament passed subsequent to the Amendment Act of 1834 the administration of relief has been affected in various ways. It would be an unprofitable task, and inconsistent with the objects and limits of this article, to give a chronological summary of those Acts down to the present time, but they are taken into account in treating of various heads of poor-law administration.

It is to be observed that the relief of the poor of every union governed by a local Act is administered by a board of guardians elected according to the Poor-Law Acts.

Although containing very important provisions, the Act of 1834 was rather to restore the scope and intention of the statute of Elizabeth by placing its administration in the hands of responsible persons chosen by the ratepayers, and themselves controlled by the orders of a central body, than to create a new system of poor laws.

The agents and instruments by which the administration of relief is afforded are the following.

The guardians of the poor regulate the cases and description of Guardian relief within the union; a certain number of guardians are elected dians from time to time by the ratepayers. The number is determined by the central board, by whom full directions as to the mode of election are given. In addition to those elected there are *ex officio* guardians, principally local magistrates. The guardians hold their meetings frequently, according to the exigencies of the union. Individual cases are brought to their notice,—most cases of resident poor by the relieving officer of the union, the case of casual paupers by him or by the workhouse officers by whom they were admitted in the first instance. The resident poor frequently appear in person before the guardians. The mode of voting which the guardians follow in respect to any matter they differ on is minutely regulated, and all their proceedings as well as those of their officers are entered in prescribed books and forms. They have a clerk, generally a local solicitor of experience, who has a variety of responsible duties in advising, conducting correspondence and keeping books of accounts, and carrying out the directions of the guardians, who in their turn are subject to the general or special regulations of the central board. The various officers of the union from the medical officer to workhouse porters, including masters and matrons of workhouses, are generally appointed by the guardians; and the duties of all the officers are specifically prescribed by the regulations issued by the central board.

Among a multitude of miscellaneous duties and powers of the guardians, apart from the ordinary duties of ordering or refusing relief in individual cases and superintending the officers of the union, the duties devolve on them of considering the adjustment of contributions to the common fund whether of divided or added parishes, and matters affecting other unions, the building of workhouses and raising of money for that and other purposes, the taking of land on lease, the hiring of buildings, special provisions as to superannuation and allowances to officers, the maintenance and orders as to lunatics apart from individual instances, and the consideration of questions of settlement and removal. A paramount obligation rests on the guardians to attend to the actual visitation of workhouses, schools, and other institutions and places in which the poor are interested, and to call attention to and report on any irregularity or neglect of duty. Guardians may charge the rates with the expenses of attending conferences for the discussion of matters connected with their duties (Poor-Law Conferences Act, 1883). In relation to expenditure the guardians have very considerable but restricted powers. Among other officers they appoint a treasurer for the union.

Overseers of the poor are still appointed under the statute of Elizabeth, and the guardians cannot interfere with the appointment. As, however, the relief of the poor is now administered by boards of guardians, the principal duties of overseers relate to the making and collecting of rates and payments. The guardians, by order of the central board, may appoint assistant overseers and collectors. Inspectors appointed by the central authority assist in the execution of the poor laws by periodically visiting and inspecting every workhouse and place wherein any poor person in receipt of relief is lodged, attending meetings of boards of guardians and every local meeting at which general questions may be raised or discussed, and taking part in meetings but not voting at them. The inspectors have great powers in calling before them and examining persons and books and proceedings. Besides the usual inspectors, persons may be appointed by the central authority to act in conducting special inquiries.

Provisions relating to expenditure and the audit of accounts are noticed in a subsequent part of this article.

Some principles connected with the system of poor-law administration call for concise notice. As the right to relief exists, the law recognizes the obligation to afford it to persons unable to maintain themselves. The refusal of the officers whose duty it is to give it is an indictable offence; and, although a means of punishment does not constitute a remedy, it seems a mandamus to guardians of the poor will, in extreme and exceptional cases, be granted. The liability to summary

proceedings now, however, operates as a preventive to neglect of duty. If, by reason of the neglect of overseers to collect rates or to pay the guardians of the poor, any relief directed by the guardians to be given to any poor person is delayed or withheld, or if overseers disobey a justice's order to give temporary relief, or if any officer wilfully neglects or disobeys the orders of the central board, penalties are incurred. The control of the central board is, except in very rare cases, found effective to secure the due administration of the law.

The recognition of the right to relief as a legal claim allows and indeed necessitates the imposition of restraints, apart from provisions connected with the law of settlement and removal, more fully noticed hereafter. Persons, however poor, wandering abroad to beg or gather alms, or placing themselves in any public place for that purpose, become subject to the vagrancy laws.

Private relief, pecuniary or otherwise, may be asked for and obtained so long as it does not involve any false pretence or dishonest or prohibited means of gaining a livelihood. Any person able by work or other means to maintain himself or his family, who, by wilful refusal or neglect to do so, becomes chargeable for any part of his family, commits an offence. Poverty or idleness short of this, and apart from the ease of liability in respect of children under elementary and industrial school Acts, is not an offence against the law.

Obliga-  
tion to  
make use  
of public  
provision.

There are circumstances, however, where relative liabilities make it a duty for persons to avail themselves of the public provision for relief. The culpable neglect of a person to provide another under his control and in his legal custody, who is actually helpless, as an infant or lunatic, with the means of life constitutes a crime, and by the express provision of a poor-law Act any parent wilfully neglecting to provide adequate food, clothing, medical aid, or lodgings for his child, being in his custody under the age of fourteen, whereby the health of such child is or is likely to be seriously injured, may be summarily convicted (31 & 32 Vict. c. 122), in analogy to the law making it an indictable misdemeanour for a master or mistress who is legally liable to provide any apprentice or servant with necessary food, clothing, or lodging, wilfully and without lawful excuse to refuse or neglect so to provide (24 & 25 Vict. c. 100). Something more than the mere abstention from seeking parochial relief without any intentional neglect is necessary to lay a criminal as distinguished from a moral responsibility on destitute persons.

Private re-  
lief not an  
offence.

Although under the vagrancy laws public begging is an offence, the giver of such unlawful charity is not subject to legal restraint. In early times attempts were made to impose such restraints. An Act of 1349 (23 Edw. III. c. 7) provided that none on pain of imprisonment should under colour of piety or alms give anything to a beggar who was able to labour, and nearly two centuries later an Act (22 Hen. VIII. c. 12) already noticed, relating to poor compelled to live by alms, and the punishment of vagabonds and beggars, provided that any person giving any harbour, money, or lodgings to any strong beggar who violated the statute should make such fine to the king as the justices in sessions should appoint; and as late as the commencement of the 17th century givers to beggars were subject to a penalty (1 Jas. I. c. 7). These Acts, however, eventually disappeared from the statute book.

Dr Burn advocated, as has been seen, the infliction of a penalty for relieving a common beggar; but, although aiders and abettors in the commission of even petty offences are now punishable, it is not attempted to apply the law to bestowers of charity, whether in the streets and highways or elsewhere.

It is in vain to impose the doctrines of political economy

in restraint of natural instincts. Such doctrines are scattered as chaff before the wind when opposed by the teachings of the nursery rhymes of "The Beggar's Petition," or to the fascinating description where the beggar figures as "a well-remembered guest," or to the sympathy enlisted by Charles Lamb's essay "A Complaint of the decay of Beggars in the Metropolis."

Although in most cases the relief given to the poor is practically a gift, and does not constitute an available debt, the plan of giving relief by way of advance as a loan was introduced early in the present century, and the Poor-Law Amendment Act (1834) enacted that any relief, or the cost thereof, which shall be given to or on account of any poor person above the age of twenty-one or to his wife or any part of his family under the age of sixteen, and which the said commissioners shall by any rule, order, or regulation declare or direct to be given or considered as given by way of loan, and whether any receipt for such relief, or engagement to pay the same, or the cost price thereof, or any part thereof, shall have been given or not by that person to or on account of whom the same shall have been so given, shall be considered, and the same is hereby declared to be, a loan to such poor person (4 & 5 Will. IV. c. 76, § 58). By the same Act power was given to enforce payment by means of a summons before justices to attach wages. A subsequent statute gives power to the guardians to recover loans to paupers in the county court (11 & 12 Vict. c. 110). By order of the central board, guardians may, in the cases within the provision of the Poor-Law Amendment Act above set out, give relief by way of loan, but no relief contrary to the regulations can be given in this way. The restriction was necessary, as formerly some guardians granted outdoor relief by way of loan contrary to the recent principles of administration of relief.

The criminal liability of parents and others *in loco parentis* to provide sustenance has been considered. The purely civil liability for necessities under implied contracts is of course outside the scope of this article, but there is an express liability created by the poor laws. The liability of the father and grandfather and the mother and grandmother and the children of poor persons under the statute of Elizabeth has been set out in an earlier part of this article. The statute extends only to natural relations. The liability is enforced by orders of magistrates after chargeability, who adjudicate as to the amount after hearing the facts and taking into consideration the ability of the relative. The relief of actual destitution should always precede investigation as to the liability of other persons than the parish to contribute to it. Indeed actual chargeability to the union is in general a condition precedent to an order upon the relative.

In treating of the persons entitled to relief it may be mentioned that, in accordance with the general law, a wife is to be treated as one with her husband who is compellable to maintain her; and, as on the one hand the wife is entitled under ordinary circumstances to relief equally with the husband, the latter is the person to apply for and to receive relief.

With respect to children, they form part of the father's family until they become "emancipated." During the minority of a child there can be no emancipation, unless he marries and so becomes himself the head of a family, or contracts some other relation so as wholly and permanently to exclude the parental control.

By the amendment of the poor laws in 1834 all relief given to or on account of the wife, or children under sixteen, not being blind or deaf and dumb, is considered as given to the husband or father as the case may be; and any relief given to children under that age of a

widow is considered as given to her (4 & 5 Will. IV. c. 76, § 56); but this provision does not interfere with the liability imposed by the statute of Elizabeth. Further a man marrying a woman having legitimate or illegitimate children is liable to maintain them as part of his family, and is chargeable with all relief on their account until they attain sixteen or until the death of the mother (*ibid.*, § 57). A married woman having separate property is liable for the maintenance of her husband and children on their becoming chargeable (45 & 46 Viet. c. 75).

The position of illegitimate children and their parents stands on a distinct foundation. By a statute of 1576 (18 Eliz. c. 3) justices were empowered at discretion to charge the mother and reputed father of bastards with their maintenance on the pain of imprisonment in default. The principle of this statute, renewed and not expressly repealed until recently, is carried out now, after receiving repeated attention, especially on the great reform of the poor laws and administration of relief in 1834, by an order of maintenance on the reputed father, at the instance of the mother, or where the child is actually chargeable to a union or parish at the instance of the guardians. Such order is in force until the child is thirteen, and in some instances until sixteen. The main features of the Acts are concisely stated in the article BASTARDY.

The exigencies of necessity are relieved.

The conditions of persons entitled to relief are indicated by the terms of the statute of Elizabeth. If they fall within the definitions there given they have right to relief. A fundamental principle with respect to legal relief of the poor is that the condition of the pauper ought to be, on the whole, less eligible than that of the independent labourer. The pauper has no just ground for complaint, if, while his physical wants are adequately provided for, his condition is less eligible than that of the poorest class of those who contribute to his support.

Although a fund has become a practical necessity, it should be always borne in mind that he who claims it is not honest if his own labour and work can suffice to provide for his wants. It is as immoral and unjust to take unnecessarily from the industrious and saving by force of a law made and a tax raised for other objects as it would be for a labourer of equal means to pillage and take from the pocket of his fellow labourer.

If a state of destitution exists, the failure of third persons to perform their duty, as a husband, or relative mentioned in the statute of Elizabeth, neglecting those he is under a legal obligation to support, is no answer to the application. The relief should be afforded, and is often a condition precedent to the right of parish officers to take proceedings against the relatives or to apply to other poor unions. The duty to give immediate relief must, however, vary with the circumstances. The case of wanderers under circumstances not admitting of delay may be different from that of persons resident on the spot where inquiry as to all the circumstances is practicable. The statute of Elizabeth contemplated that the relief was to be afforded to the poor resident in the parish, but it is contrary to the spirit of the law that any person shall be permitted to perish from starvation or want of medical assistance. Whoever is by sudden emergency or urgent distress deprived of the ordinary means of subsistence has a right to apply for immediate relief where he may happen to be. Persons comprehended within this class are called "casual poor," although the term "casuals" is generally used in reference to vagrants who take refuge for a short time in the "casual wards" of workhouses.

Various tests are applied to ascertain whether applicants are really destitute. Labour tests are applied to the able-bodied, and workhouse tests are applied to those to whom entering a workhouse is made a condition of relief.

Nature and kind of relief. As to the nature and kind of relief given under the poor laws the great distinction restored rather than introduced by the amendment of the poor-law system in 1834 was giving all relief to able-bodied persons or their families

in well-regulated workhouses (that is to say, places where they may be set to work according to the spirit and intention of the statute of Elizabeth), and confining outdoor relief to the impotent—that is, all except the able-bodied and their families. Although workhouses formed a conspicuous feature in legislation for the poor from an early period, the erection of those buildings for unions throughout the country where not already provided followed immediately on the amendment of the system in 1834. Since that time there has been a constant struggle between the pauper class and the administrators of the law, the former naturally wishing to be relieved at their own homes, and in many instances choosing rather to go without aid than to remove within the walls of the workhouse.

Relief given in a workhouse is termed "in (or indoor) maintenance" relief, and when given at the homes of the paupers is termed "outdoor relief." The regulations, accounts, and returns to parliament, as well as the principles governing relief, are based on these distinctions. It is impossible, however, to apply rigid principles very closely, or rather the exceptions in practice are so numerous that the majority of resident poor are relieved at their own homes by being supplied with necessaries in kind, or by payment either wholly or in part in coin, as circumstances are held to demand or warrant. The general order is that every able-bodied person, male or female, requiring relief shall be relieved only in the workhouse, together with such of the family as may be resident with such able-bodied person, and not in employment, including his wife residing with him. The exceptions made are where the person requires relief on account of sudden and urgent necessity, or on account of any sickness, accident, or bodily or mental infirmity affecting such person or any of his family; where relief is required for the purpose of defraying the expenses of burial of any of the family; in the case of widows, relief in the first six months of her widowhood when she has legitimate children dependent upon her incapable of earning a livelihood, and has no illegitimate children born after her widowhood. Further relief in or out of the workhouse may be given by guardians in their discretion to a wife or children of an able-bodied man not resident within the union.

By the Industrial School Act any child found begging or receiving alms (whether actually or under the pretext of selling or offering for sale anything), or being in any street or public place for the purpose of begging or receiving alms, or found wandering and not having any home or settled place of abode or proper guardianship or visible means of subsistence, or found destitute, either being an orphan or having a surviving parent who is undergoing penal servitude or imprisonment, or that frequents the company of reputed thieves (as also in some other cases recently added), may be sent to a certified industrial school, and while a school is being found justices may order detention for a week in the workhouse.

In the metropolis justices have power to cause inmates of dangerous structures to be received into a workhouse.

Besides workhouses, district asylums are provided for the destitute poor in certain places. Under the Poor-Law Amendment Act, 1844, reciting that it was expedient that more effectual means should be provided for the temporary relief of poor persons found destitute and without lodgings within the district of the metropolitan police or the city of London, and in Liverpool, Manchester, Bristol, Leeds, and Birmingham, district boards were established, by which provision is made for such temporary relief and setting to work therein of any poor person found destitute within any such district, not professing to be settled in any parish included in it and not known to have any place of abode there and not charged with any offence under the Vagrant Act.

In 1867 under the Metropolitan Poor Act of that year unions and parishes in the metropolis were by order of the board formed into asylum districts, in each of which there is one asylum or more for the reception and relief of the sick, insane, or infirm, under a body of managers partly elective and partly nominated by the board, who build or hire asylums and furnish them, and appoint committees. The attendance at the asylum of a special commissioner of lunacy is provided for. Special provision is made as well for outdoor as indoor medical relief by providing dispensaries and the dispensing of medicines, with regulations for the appointment of medical officers in the district.

The necessarily large expenditure for the asylums is principally defrayed by a fund called the metropolitan common poor fund, by contributions from the several unions, parishes, and places in the metropolis. The amount of the respective assessments is determined by the local government board according to the valuation lists (noted hereafter) or on such other basis as the board directs, the contribution being enforced by a precept of the board; and the bodies called on to pay levy the amount by a rate on occupiers of rateable property in the nature of a poor rate.

Work-  
house  
rules.

Admission to a workhouse may be by a written order of the board of guardians, or by the master or matron (or in their absence by the porter) without an order in any case of sudden or urgent necessity, or provisionally by a relieving officer, or overseer, or churchwarden. Any person who is brought by a policeman as having been found wandering in a state of destitution may be admitted. It is to be observed generally, with respect to all persons who may apply for admission into the workhouse under circumstances of urgent necessity, that their destitution, coupled with the fact of being within the union or parish, entitles them to relief, altogether independently of their settlement (see below), if they have one, which is a matter for subsequent inquiry.

The regulations for the government of workhouses fall under two classes:—(1) those which are necessary for the maintenance of good order in any building in which considerable numbers of persons of both sexes and of different ages reside; (2) those which are necessary in order that these establishments may not be almshouses, but workhouses in the proper meaning of the term.

The inmates of a workhouse are necessarily separated into certain classes. In no well-managed institution of this sort, in any country, are males and females, the old and the young, the healthy and the sick, indiscriminately mixed together. The general classification of paupers in the workhouse so far as the structure admits is as follows:—Class 1, men infirm through age or any other cause; Class 2, able-bodied men, and youths above the age of fifteen; Class 3, boys above the age of seven and under fifteen; Class 4, women infirm through age or any other cause; Class 5, able-bodied women, and girls above fifteen; Class 6, girls above seven and under fifteen; Class 7, children under seven. To each class is assigned that ward or separate building and yard which may be best fitted for the reception of such class, and each class is without communication with those of any other class. Guardians are required to divide the paupers into the seven classes, and to subdivide any one or more of these classes in any manner which may be advisable, and which the internal arrangements of the workhouse admit; and the guardians are required from time to time, after consulting the medical officer, to make necessary arrangements with regard to persons labouring under any disease of body or mind, and, so far as circumstances permit, to subdivide any of the enumerated classes with reference to the moral character or behaviour or the previous habits of the inmates, or to such other grounds as may seem expedient.

For example, it is very desirable that females of dissolute and disorderly habits should be separated from those of a good character, for it is the duty of the guardians to take all reasonable care that the morals of persons admitted into the house be not corrupted by intercourse with inmates of this description; but this has reference to continued ill-conduct, and is not in any way to be a punishment for offences committed previous to entrance into the workhouse and discontinued before admission.

The separation of married couples was long a vexed question, the evils on the one hand arising from the former unrestricted practice being very great, while on the other hand the separation of old couples was felt as a great hardship, and by express statutory provision in 1847 husband and wife, both being above the age of sixty, received into a workhouse cannot be compelled to live separate and apart from each other (10 & 11 Vict. c. 109, § 23). This exemption was carried somewhat further by contemporaneous orders of the board, under which guardians were not compelled to separate infirm couples, provided they had a sleeping apartment separate from that of other paupers: and in 1876 guardians were empowered, at their discretion, to permit husband and wife where either of them is infirm, sick, or disabled by any injury, or above sixty years of age, to live together, but every such case must be reported to the local government board (32 & 40 Vict. c. 61, § 10).

Children under seven are placed in such of the wards appropriated to female paupers as may be deemed expedient, and their mothers are permitted to have access to them at all reasonable times; fathers or mothers who may be desirous of seeing any child who is in the same workhouse have a daily interview; and arrangements are made for permitting members of the same family who are in different workhouses of the union to have occasional interviews with each other at such times and in such manner as best suits the discipline of the several workhouses.

Casual and poor wayfarers admitted by the master and matron are kept in a separate ward and dieted and set to work in such manner as the guardians by resolution direct; and whenever any vagrants or mendicants are received into a workhouse they ought (as a precaution necessary for preventing the introduction of infectious or contagious diseases) to be kept entirely separate from the other inmates, unless their stay exceeds a single night.

The guardians may direct that any pauper inmate of the workhouse of any class, except casual paupers, shall be detained in the workhouse after giving notice to the guardians, for limited periods. A casual pauper (that is, any destitute wayfarer or wanderer applying for or receiving relief) is not entitled to discharge himself from a casual ward before the second day following his admission,

or of the fourth day if he has been previously admitted more than once within a month, nor before he has performed the work prescribed for him (Casual Poor Act, 1882).

Infirmaries are attached to many workhouses, especially in the metropolis, and also in some cases there are infirmaries for the poor distinct from the workhouse; all are governed and regulated under the orders of a central board.

The outdoor labour test order of the local government board directs that every able-bodied male pauper who may receive relief within the union out of the workhouse shall be relieved in the following manner:—half at least of the relief given to such pauper shall be given in food, clothing, and other articles of necessity, and no such pauper shall receive relief from the guardians of the union or any of their officers or any overseer while he is employed for wages or other hire or remuneration by any person; but every such pauper shall be set to work by the guardians. The kind of work is reported to the board. A departure from the order is, however, permitted if approved by the board.

To prevent the practice formerly prevailing in some parts whereby the poor rates were used for the payment of rents directly to the landlords, the guardians and parish officers are prohibited from paying the rent of the house or lodging of any pauper, or applying any relief in such payment directly or indirectly. This does not apply, however, to any shelter or temporary lodging procured in any case of sudden and urgent necessity, or mental imbecility; nor does it prevent the guardians, in regulating the amount of relief to be afforded to any particular person, from considering the expense to be incurred in providing lodging. This allows of supplying to the pauper the means of paying for a lodging instead of requiring him to come into the workhouse in such exceptional cases.

Modern remedial legislation and public efforts connected with improved dwellings for labourers and artisans, as well as for the poor generally, are distinct from the laws for the compulsory relief of the poor,—although, like education, the whole subject of amelioration of classes admits in some of its aspects of being viewed together. The allotment of land to industrious poor has been also of great service (Allotments Extension Act, 1882).

Guardians having greater provision for the reception of poor children in their workhouse than they require may with the consent of the board contract with the guardians of any other union or parish for the reception, maintenance, and instruction of any poor children under sixteen being orphans or deserted by their parents or whose parents consent (14 & 15 Vict. c. 105; 29 & 30 Vict. c. 113).

A consolidated order comprising workhouse regulations prescribes that the boys and girls who are inmates of a workhouse shall, for three of the working hours at least every day, be instructed in reading, writing, arithmetic, and the principles of the Christian religion, and such other instruction shall be imparted to them as may fit them for service, and train them to habits of usefulness, industry, and virtue. Education and schools.

In relation to education of poor children out of the workhouse there has been much legislation. To go no farther back, the Act of 1855, providing for the education of children in the receipt of outdoor relief (18 & 19 Vict. c. 34, known as Denison's Act), was superseded in 1873 by the Elementary Education Act of that year (36 & 37 Vict. c. 86), containing a special clause for the education of children relieved out of the workhouse and the payment of school fees, but this clause was in turn repealed by the Elementary Education Act, 1876 (39 & 40 Vict. c. 79), making it the duty of every parent to cause a child to receive efficient elementary instruction in reading, writing, and arithmetic. See EDUCATION.

By this Act a provision substituted for that of 1873 enacts that where relief out of the workhouse is given by the guardians or by their order by way of weekly or other continuing allowance to the parent of any child above the age of five years who has not reached the standard in reading, writing, and arithmetic prescribed by a certain code, or who for the time being either is prohibited by the Act from being taken into full time employment, or who by any bye-law under the earlier Elementary Education Act of 1870 is required to attend school, it shall be a condition for the continuance of such relief to the parent or child that elementary education in reading, writing, and arithmetic shall be provided for such child, and the

guardians are required to give such further relief (if any) as may be necessary for that purpose. Such relief cannot be granted on condition of the child attending any public elementary school other than such as may be selected by the parent, nor refused because the child attends or does not attend any particular public elementary school. Moreover the guardians have no power under this provision to give any relief to a parent in order to enable such parent to pay more than the ordinary fee payable at the school which he selects, or more than the fee which under the provisions of the Act they can enable a parent to pay in any other case. All relief given by the guardians under this provision is deemed to be relief within the meaning of the poor laws and payable out of their common fund (39 & 40 Viet. c. 79, § 40; see also § 34). A child cannot, as a condition of the continuance of relief out of the workhouse under the above provision, be required to attend school further or otherwise than is obligatory by any bye-law of a school board (43 & 44 Viet. c. 23, § 5).

Money given for the payment of school fees for any child of a parent who is not a pauper and is resident in any parish is charged by the guardians having jurisdiction to that parish with other parochial charges (39 & 40 Viet. § 35).

The education of poor children is closely connected with the system of "boarding out," as it is termed. The guardians of certain unions are empowered to board out pauper children in homes beyond the limits of the union, provided the guardians have entered into approved arrangements which include education (boarding-out order 1870); and by a statute of 1862 (still unrepealed, except so far as by implication provisions are superseded) the guardians of any parish or union may send any poor child to any school certified to the board as fit for their reception and charge the expenses in the same manner as other relief. Unless an orphan or deserted or having the consent of a parent, a child cannot be sent under this statute, and no child can be kept against its will if above fourteen. Such school is open to inspection (25 & 26 Viet. c. 43).

Under the last-mentioned statute, the amount which might be paid by a board of guardians for the maintenance of a child in an institution certified under that statute was limited to the cost of the maintenance of the child in the workhouse; but by the Divided Parishes and Poor-Law Amendment Act, 1882, the guardians may pay the reasonable expenses incurred in the maintenance, clothing, and education of the child to an amount sanctioned by the local government board. The board has accordingly sanctioned rates of payment, and in practice, when issuing a certificate, specifies the maximum amount which may be paid by the guardians as a reasonable allowance towards the maintenance of any pauper child sent to the institution.

It is to be observed that the provisions of the Elementary Education Acts as to the employment of children by employers in school districts not within the jurisdiction of a school board, consisting of a parish and not a borough, must be enforced by the school committee of guardians of the union (39 & 40 Viet. c. 79, § 7).

The daily average number of children of both sexes attending the schools of the union workhouses, &c., in England and Wales during the half-year ended at Lady Day 1883 was 26,170. Added to this total there is the average daily attendance at district schools, 7488, and 485 in the metropolitan asylum district, making a total of 34,146. The amount paid to boards of guardians and managers out of the parliamentary grant in respect of the salaries of workhouse and district school teachers for the year ending Lady Day 1883 was £38,629, 11s.

Various provisions relating to the apprenticeship of poor children have been noticed in tracing the progress of legislation. Guardians are not restricted from binding as apprentices children who are not actually in the receipt of relief or whose parents may not be in the receipt of relief as paupers at the time of the binding. Such children as may ordinarily be considered "poor children" are within the scope of the provisions respecting the apprenticeship of pauper children. But apprenticeship under the poor laws is a species of relief which can only be given subject to the general or special regulations on the subject.

The general orders direct that no child under the age of nine years and no child (other than a deaf and dumb child) who cannot read and write his own name shall be bound apprentice by the guardians, and no child is bound to a person who is under twenty-

one or who is a married woman, or to a person who is not a house-keeper or assessed to the poor rate in his own name, or who is a journeyman or a person not carrying on trade or business on his own account. And no child can be bound, unless in particular cases, to a master whose place of business is more than 30 miles from the residence of the child at the time of binding. The term of apprenticeship is discretionary with the guardians, but no apprentice can be bound for more than eight years, and if the child is above fourteen his own consent is required. If under sixteen his father's consent (or, if his father is dead, his mother's if living) is necessary. Various preliminaries to the binding are requisite, affecting the health and strength of the child and all attendant circumstances. When any premium is given it must in part consist of clothes supplied to the apprentice and in part of money to the master. The duties of the master of a pauper apprentice are specially provided for both by statute and by the regulations adopted by the local government board.

In the administration of medical relief to the sick, the Medical objects kept in view are—(1) to provide medical aid for relief persons who are really destitute, and (2) to prevent medical relief from generating or encouraging pauperism, and with this view to withdraw from the labouring classes, as well as from the administrators of relief and the medical officers, all motives for applying for or administering medical relief, unless where the circumstances render it absolutely necessary.

Unions are formed into medical districts limited in area and population, to which a paid medical officer is appointed, who is furnished with a list of all such aged and infirm persons and persons permanently sick or disabled as are actually receiving relief and residing within the medical officer's district. Every person named in the list receives a ticket, and on exhibiting it to the medical officer is entitled to advice, attendance, and medicine as his case may require. Medical outdoor relief in connexion with dispensaries is regulated in asylum districts of the metropolis by the Metropolitan Poor Act, 1867 (30 & 31 Viet. c. 6).

A lunatic asylum is required to be provided by a Pauper county or borough for the reception of pauper lunatics, with a committee of visitors who, among other duties, fix a weekly sum to be charged for the lodging, maintenance, medicine, and clothing of each pauper lunatic confined in such asylum. Medical officers of unions and parishes, having knowledge that any resident pauper is or is deemed to be a lunatic, give written notice to relieving officers or other officers, and such officers, having knowledge either by such notice or otherwise of the fact, must apply to a justice, who requires the relieving officer to bring the pauper before him, or some other justice, calling to his assistance a duly qualified medical man (physician, surgeon, or apothecary), and upon his certificate, and the justice upon view or examination or other proofs being satisfied that such pauper is a lunatic and a proper person to be taken charge of and detained under care and treatment, a written order is made out directing the pauper to be received into such asylum. That is the ordinary mode, but justices may act on their own knowledge, and police officers have power to apprehend wandering lunatics and take them before justices.

The Metropolitan Poor Act, 1867, already noticed, contains many provisions applicable to insane poor, including the right of the commissioners of lunacy to visit the asylums.

In some cases when duly authorized a lunatic may be received into a registered hospital or house duly licensed for the reception of lunatics. No lunatics can be kept in a workhouse more than fourteen days except under special circumstances; minute provisions are made for the care, visitation, and discharge of the lunatics. The central board has made regulations respecting the detention of harmless idiots and other insane persons.

The cost of removal and maintenance is borne by the common fund of the union, and justices sending the pauper, or the visiting justices of an asylum may draw upon the guardians for the amount of the pauper's maintenance in favour of the treasurer, officer, or proprietor of the asylum. Any property of the lunatic is applicable to his maintenance. Special provision is made for inquiry into the settlement and adjudicating it, and for payment of costs of maintenance in accordance with the adjudication (16 & 17 Viet. c. 97, and subsequent Acts). There are also special provisions as to pauper criminal lunatics and sending them to an asylum at the cost of the common fund of the union as in other cases,—to which

Apprenticeships.

expenses, however, the person's property, if he have any (Criminal Lunatics Act, 1884, and Acts there referred to), is applicable.

An increase has taken place for many years past in the number of lunatic paupers. The total number of this class of paupers relieved on 1st January 1883 was larger by 1867 than it was on the corresponding day in 1882.

Settle-  
ment.

A settlement is the right acquired in any one of the modes pointed out by the poor laws to become a recipient of the benefit of those laws in that parish or place where the right has been last acquired.

No relief is given from the poor rates of a parish to any person who does not reside within the union, except where such person being casually within a parish becomes destitute by sudden distress, or where such person is entitled to receive relief from any parish where non-resident under justice's order (applicable to persons under orders of removal and to non-resident lunatics), and except to widows and legitimate children where the widow was resident with her husband at the time of his death out of the union in which she was not settled, or where a child under sixteen is maintained in a workhouse or establishment for the education of pauper children not situate in the union, and in some other exceptional cases.

The progress of the law of settlement may be gathered from the statutes already referred to; and, without again adverting to legislation already noticed, and much more not enumerated, it must be sufficient to point out that immediately before the passing of the Poor-Law Amendment Act, 1834, settlements were acquired by birth, hiring and service, apprenticeship, renting a tenement, estate, office, or payment of rates. In addition to these an acknowledgment (by certificate, of which mention has been made, by relief or acts of acquiescence) has practically the effect of a settlement, for, if unexplained, such an acknowledgment stops the parish from disputing a settlement in the parish acknowledging. The Poor-Law Amendment Act, 1834, abolished settlement by hiring and service (or by residence under it) and by serving an office, and by apprenticeship in the sea service. Moreover the guardians of a union might agree (subject to the approval of the commissioners) that all the parishes forming it should for the purposes of settlement be considered as one parish.

It is to be observed that, for the purposes of relief, settlement, and removal and burial, the workhouse of any parish is considered as situated in the parish to which each poor person is chargeable.

There may be a settlement by parentage, for legitimate children take the settlement of their father, or if he has no settlement they are entitled to the settlement of their mother; and it is only when both these sources fail discovery that their right of settlement by birth accrues; for until the settlement of the father or mother has been ascertained the settlement of a legitimate child, like that of a bastard, is in the place where the birth took place.

A settlement attaches to those persons who have a settlement of some kind. Foreigners born out of the country and not acquiring any in one of the modes pointed out must be provided for, if requiring relief, where they happen to be.

Irremov-  
ability.

As the burden of maintaining the poor is thrown on the parish of settlement, when the necessity for immediate relief arises in another parish the important question arises whether the pauper can be removed; for, although the parish where the pauper happens to be must afford immediate relief without waiting for removal, the parish of settlement cannot in general be charged with the cost unless the pauper is capable of being removed. The question of removability is distinct from settlement. A pauper often acquires a status of irremovability without gaining a settlement.

Irremovability is a principle of great public importance quite irrespective of the incident of cost as between one parish or another. Before the introduction of a status of irremovability removal might take place (subject to powers of suspension in case of sickness and otherwise) after any interval during which no legal settlement was obtained; mere length of residence without concurrent circumstances involving the acquisition of a settlement on obtaining relief gave no right to a person to remain in the parish where he resided.

In 1846 it was enacted that no person should be removed nor any warrant granted for the removal of any

person from any parish in which such person has resided for five years (9 & 10 Vict. c. 66). In 1861 three years was substituted for five (24 & 25 Vict. c. 55); and only four years later one year was substituted for three (28 & 29 Vict. c. 79). Apart from these reductions of time in giving the status of irremovability, actual removals to the parish of settlement were narrowed by provisions giving to residence in any part of a union the same effect as a residence in any parish of that union (24 & 25 Vict. c. 55). On the other hand the time during which parish relief is received, or during which the person is in any poorhouse or hospital or in a prison, is excluded from the computation of time (9 & 10 Vict. c. 66).

The removability as well as the settlement of the family, i.e., of the wife and unemancipated children, are practically subject to one and the same general rule. Wherever any person has a wife or children having another settlement, they are removable where he is removable, and are not removable from any parish or place from which he is not removable (11 & 12 Vict. c. 211).

It is to be borne in mind that no person exempted from liability to be removed acquires, by reason of such exemption, any settlement in any parish; but a residence for three years gives a qualified settlement (39 & 40 Vict. c. 61).

The cost of relief of paupers rendered irremovable is borne by the common fund of the union (11 & 12 Vict. c. 110, § 3) as union expenses (§ 6), and any question arising in the union with reference to the charging relief may be referred to and decided by the local government board (§ 4).

The statute of Elizabeth required overseers to account to justices for all moneys received by them under rules or otherwise, and all expenditure for the relief of the poor, and to deliver over balances to their successors (43 Eliz. c. 2, § 2). By the amendment of the poor laws in 1834 the duty of making payments was thrown chiefly on the guardians, leaving the overseers to assess and collect the rates out of which such payments are chiefly made. The accounts of expenditure and receipts by all parties, including officers of union and treasurers, form a very important part of poor-law administration. The duties, including the forms of books of account, are minutely prescribed by orders of the central board, and the accounts are examined and audited half-yearly by auditors appointed by the board in auditory districts, the auditing by justices having ceased. Full powers are given to the auditors to make this examination effectual and to allow and disallow accounts and items in them (see the Poor-Law Amendment Act, 1868, and Acts there recited).

It is to be observed that by various provisions in the poor-law Acts power has been given to raise money by borrowing. The Poor-Law Amendment Act 1835 authorizes applications for advances under several earlier Acts for building or enlarging workhouses or for purchasing land, and a subsequent Act authorizes the borrowing of money for payment of debts generally (5 & 6 Vict. c. 15).

The principal items comprised in the total amount expended in the relief of the poor in England and Wales during the years ending at Lady Day 1882 and 1883 are these:—

	1882.	1883.
1. Indoor maintenance.....	£1,831,595	£1,869,505
2. Outdoor relief.....	2,626,375	2,589,937
3. Maintenance of lunatics in asylums or licensed houses.....	1,059,460	1,098,322
4. Workhouse and other loans repaid and interest.....	351,208	430,185
5. Salaries and rations of officers, and superannuations.....	1,087,641	1,117,705
6. Other expenses of, or immediately connected with, relief.....	1,296,523	1,303,416
Total relief to the poor.....	£8,252,797	£8,409,070
Deductions <sup>1</sup> .....	20,325	55,778
Adjusted cost of relief.....	£8,232,472	£8,353,292

<sup>1</sup> To be made in consequence of the payments from the metropolitan common poor fund exceeding the payments made to that fund during each year.

The comparison between the two years shows that with the exception of the outdoor relief there has been an increase in each item of expenditure. In this respect the year 1882-83 forms no exception to its predecessors, for the out relief is the only item in which there has been any decrease of late years.

Bringing the expenditure down to a later period, the comparative cost of the half years ended at Lady Day 1883 and 1884 stood thus:—1883, in maintenance £982,586, out relief £1,260,700, total £2,252,286; 1884, in maintenance £978,287, out relief £1,226,730, total £2,205,017. Therefore the cost for the half year 1884 had decreased—the in maintenance by £4299, and the outdoor relief by £42,970. The average price of wheat per imperial quarter during the same half years was—1883, 40s. 11d.; 1884, 38s. 11d.

In the article LONDON tables have been given of the system of poor relief there. It must suffice here to notice that the cost of relief in the metropolis, comprising thirty unions, has increased since 1875. On the other hand the proportion which the cost of outdoor relief bears to the cost of in maintenance in the metropolis is continually decreasing. In 1883 the in maintenance was £568,933 and the outdoor relief £199,013. The expenditure for in and out relief in the metropolis for the Lady Day half years 1883 and 1884 stood thus—1883, £417,614; 1884, £425,310, an increase of £7696. In the parochial year 1883 the adjusted cost of relief was £2,172,294, being equal to a rate of 1s. 6½d. on the rateable value.

It is satisfactory to find that the adult able-bodied paupers have been steadily diminishing in numbers during the last four years, both among indoor and outdoor paupers. Comparing 1883 with 1873, it appears that there has been a diminution of 23,775, or no less than 29·6 per cent., in the mean number of adult able-bodied persons receiving relief, and, if we take into account the increased population, we find that the diminution has been 30·9 per cent. In the parochial year 1883 the mean number of adult able-bodied paupers was—indoor 21,558, outdoor 77,592, total 99,150. The above numbers do not include vagrants.

Although for many reasons it is considered desirable that as far as practicable out relief should be given in kind rather than in money, it will be seen by the following table for the parochial year 1883 taken from the unaudited half-yearly statements (and exclusive of relief given by the guardians in respect of school fees) how much more is given in money:—

Poor-Law Districts.	Out-Door Relief.	
	In Money.	In Kind.
The metropolis.....	£156,272	£38,623
South-eastern.....	198,657	52,029
South-midland.....	193,333	34,606
Eastern.....	126,155	55,456
South-western.....	298,371	29,146
West-midland.....	254,989	36,378
North-midland.....	176,268	8,248
North-western.....	262,070	14,366
York.....	234,644	12,967
Northern.....	127,113	1,639
Wales.....	252,487	10,824
Total.....	£2,250,319	£294,312

The great difference which exists in the several divisions in the manner of administering out relief is apparent. In the eastern division (comprising Essex, Suffolk, and Norfolk) nearly one-third of the outdoor relief was given in kind; while in the northern division (comprising Northumberland, Durham, Cumberland, and Westmoreland) nearly the whole was given in money.

The cost per head of relief on the mean number was in 1882 £10, 13s. 6d.; in 1873 it was £8, 14s. 1d.

It may be stated here that, whilst in the metropolis the cost of outdoor relief was in 1883 little more than one-third of that of the in maintenance, the expenditure on out relief in the remainder of England, with the exception of the north-western division, was considerably in excess of that on in maintenance, being in Wales more than four and a half times as great.

The mean number of paupers relieved in 1883 was—indoor 182,932, and out paupers (inclusive of those chargeable to the poor rates who are in county and borough asylums or in licensed houses) 599,490, or a total mean number of 782,422, being a ratio of 29·6 per 1000 of the population. The mean number of paupers relieved in 1883 was smaller in proportion to the population by 101,266 (or 11·5 per cent.) than the mean number relieved in 1873, ten years before—a decrease, however, entirely owing to a reduction in the number of outdoor paupers.

Some remarkable fluctuations took place in the number of vagrants relieved during the ten years ending in 1883. In 1873 the mean number of this class of paupers was 2700. In 1881 it had risen to 6979, an increase of 158·5 per cent. In 1883 it had fallen to 4790. After the end of that parochial year it still further

decreased owing to the operation of the Casual Poor Act, 1882, extending the periods for which vagrants may be detained in casual wards.

The increased cost of relief is attributable to some extent to the fact that the proportion which the mean number of paupers relieved in the workhouse bears to the mean number of paupers of all classes is larger than it formerly was; but it is also attributed partly to expenses incurred in the erection of improved buildings, the substitution of paid officers for pauper help, and other similar items of expenditure incurred for the purpose of securing the more efficient administration of relief. The yearly cost per head on the mean number of outdoor paupers has diminished during the last few years, and was smaller during 1883 than in any other year since 1873 with the exception of the year 1880.

The poor rate is the fund from which the cost of relief Poor is principally derived. The parochial taxation for this rate purpose in the statute of Elizabeth has been already noticed. As regards the subject matter of taxation the only subsequent absolute interference is in relation to saleable underwood, and also to rights of fowling, shooting, or taking game or rabbits, and of fishing, where severed from the occupation of lands, and to mines of every kind not mentioned in the Act (see the Rating Act, 1874). The statute of Elizabeth enforced what are called duties of imperfect obligation; for it was, as has been seen, a duty before that statute to relieve the poor and necessitous, and the provisions of that Act were adapted to the enforcing of those duties in the way in which they could be practically carried out by enabling the parish officers to tax the inhabitants, whose representatives those officers are, for the actual performance of the obligations.

The Act gives persons aggrieved by any such tax a right of appeal—a right which has been fully exercised as well as regulated and affected by much subsequent legislation. By the Parochial Assessment Act, 1836 (6 & 7 Will. IV. c. 96), closely following the poor-law amendment of two years before, no rate for the relief of the poor is of any force which is not made upon an estimate of the net annual value of the several hereditaments rated, that is to say, of the rent at which the same might reasonably be expected to let from year to year free of all usual tenant's rates and taxes, and tithe commutation rent charge, if any, and deducting therefrom the probable average annual cost of the repairs, insurance, and other expenses, if any, necessary to maintain them in a state to command such rent.

Nothing in the Act, however, altered or affected the principles or different relative liabilities according to which different kinds of hereditaments were previously liable. The statute of Elizabeth (extended in some respects as to places by 13 & 14 Charles II. c. 12) embraced two classes of persons subject to taxation—occupiers of real property and inhabitants in respect of personal property, although the rateability under the latter head was reluctantly conceded by the courts of law, and was in practice only partially acted upon. Inhabitants as such, in respect of ability derived from the profits of stock in trade or any other property, were, however, expressly relieved in 1840 by a temporary Act (3 & 4 Vict. c. 89), since continued from time to time. It is solely by expiring laws continuance Acts (the last Act extending to the end of 1885) that the vast amount of personal property is relieved from the poor rate. This exemption, and the principle on which it is based, of course forms an important element in all questions of local and in many of imperial taxation.

As regards occupiers of land and houses, the correct principles as to the persons liable to be rated were, after many erroneous views and decisions, established by the House of Lords in 1865 in the case of the Mersey docks. The only occupier exempt from the operation of the Act of Elizabeth is the crown, on the general principle that such liabilities are not imposed on the sovereign unless expressly mentioned, and that principle applies to the direct and immediate servants of the crown, whose occupation is the occupa-

tion of the crown itself. If there is a personal private beneficial occupation, so that the occupation is by the subject, that occupation is rateable. Thus for apartments in a royal palace, gratuitously assigned to a subject, who occupies them by permission of the sovereign but for the subject's benefit, the latter is rateable; on the other hand, where a lease of private property is taken in the name of a subject, but the occupation is by the sovereign or her subjects on her behalf, no rate can be imposed.

So far the ground of exemption is perfectly intelligible, but it has been carried a good deal further, and applied to many cases in which it can scarcely be said naturally, but only theoretically, that the sovereign or the servants of the sovereign are in occupation. A long series of cases have established that when property is occupied for the purposes of the government of the country, including under that head the police, and the administration of justice, no one is rateable in respect of such occupation. And this applies not only to property occupied for such purposes by the servants of the great departments of state and the post office, the Horse Guards, and the Admiralty, in all which cases the occupiers might strictly be called the servants of the crown, but to county buildings occupied for the assizes and for the judge's lodgings, to stations for the local constabulary, to jails, and to county courts where undertakings are carried out by or for the Government and the Government is in occupation; the same principles of exemption have been applied to property held by the office of works.

When the property is not *de facto* occupied by the crown or for the crown, it is rateable; and, although formerly the uses of property for public purposes, even where the crown was not constructively interested in the way above pointed out, was treated as a ground for exemption, it is now settled that trustees who are in law the tenants and occupiers of valuable property in trust for public and even charitable purposes, such as hospitals or lunatic asylums, are in principle rateable notwithstanding that the buildings are actually occupied by paupers who are sick or insane, and that the notion that persons in the legal occupation of valuable property are not rateable if they occupy in a merely fiduciary character cannot be sustained.

With respect to the particular person to be rated where there is a rateable occupation, it is to be observed that the tenant, as distinguished from the landlord, is the person to be rated under the statute of Elizabeth; but occupiers of tenements let for short terms may deduct the poor-rate paid by them from their rents, or the vestries may order such owners to be rated instead of the occupiers; such payments or deductions do not affect qualification and franchises depending on rating (Poor-Rate Assessment and Collection Act, 1869, and Amendment Act, 1882).

To be rated the occupation must be such as to be of value, and in this sense the word beneficial occupation has been used in many cases. But it is not necessary that the occupation should be beneficial to the occupier; for, if that were necessary, trustees occupying for various purposes, having no beneficial occupation, would not be liable, and their general liability has been established as indicated in the examples just given.

As to the mode and amount of rating it is no exaggeration to say that the application of a landlord-and-tenant valuation in the terms already given in the Parochial Assessment Act, with the deductions there mentioned, has given rise to litigation on which millions of pounds have been spent within the last half century, with respect to the rating of railways alone, although the established principle applied to them, after much consideration, is to calculate the value of the land as increased by the line.

The Parochial Assessment Act referred to (6 & 7 Will. IV. c. 96), comprising various provisions as to the mode of assessing the rate so far as it authorized the making of a valuation, was repealed in 1869, in relation to the metropolis, and other provisions made for securing uniformity of the assessment of rateable property there (32 & 33 Viet. c. 67).

The mode in which a rate is made and recovered may be concisely stated thus. The guardians appoint an assessment committee of their body for the investigation and supervision of valuations, which are made out in the first instance by the overseers according to specific regulations and in a form showing among other headings the gross estimated rental of all property and the names of occupiers and owners, and the rateable value after the deductions specified in the Assessment Act already mentioned, and as prescribed by the central board. This valuation list, made and signed by the overseers, is published, and all persons assessed or liable to be assessed, and other interested parties, may, including the officers of other parishes, inspect and take copies of and extracts from that list. A multitude of provisions exist in relation to the valuation and supplemental valuation lists. Objections on the ground of unfairness or incorrectness are dealt with by the committee, who hold meetings to hear and determine such objections. The valuation list, when approved by the committee, is delivered to the overseers, who proceed to make the rate in accordance with the valuation lists and in a prescribed form of rate book. The parish officers certify to the examination and comparison of the rate book with the assessments,

and obtain the consent of justices as required by the statute of Elizabeth. This consent or allowance of the rate is merely a ministerial act, and if the rate is good on the face of it the justices cannot inquire into its validity.

The rate is then published and open to inspection. Appeals may be made to special or quarter sessions against the rate, subject to the restriction that, if the objection were such that it might have been dealt with on the valuation lists, no appeal to sessions is permitted unless the valuation list had been duly objected to and the objector had failed to obtain such relief in the matter as he deemed to be just (see Union Assessment Acts).

In the metropolis a common basis of value for the purposes of government and local taxation is provided, including the promotion of uniformity in the assessment of rateable property. Provision is made for the appointment of an assessment committee by guardians or vestries, and for the preparation of valuation lists, and the deposit and distribution of valuation lists, and for the periodical revision of valuation lists. Appeals against the valuation list are heard by justices in special sessions, upon whom special limited powers are conferred. General assessment sessions, principally for appeals affecting the total of the gross or rateable value of any parish as being too high or too low as compared with other parishes, are appointed for hearing and determining appeals, and the lists are altered in accordance with their decisions. Those decisions may be questioned as in the case of decisions by courts of general or quarter sessions.

The valuation lists as approved by the assessment committee, or as altered on appeal, last for five years, and are conclusive evidence of gross and rateable value for the purpose of various specified rates, including the poor rate; and the poor rate is made by the parish officers in accordance with such valuation according to a form provided,—see Valuation (Metropolis) Act, 1869.

It is to be borne in mind that the amount raised by poor rates does not closely represent the amount actually expended on the relief of the poor. The rates are made in reference to the prospective amounts required, and various payments not connected with the maintenance of the poor are charged by various Acts of Parliament on the poor rate.

Payment of poor rates, and of the costs incurred, is enforced on complaints to justices, and by distress warrants and imprisonment in default. Special statutory provision is made for this mode of recovery.

In conclusion, while giving full credit to the admirable way in which the English poor-law system, and the principles on which it is based, have been and continue to be promulgated and explained by the central authority to the guardians and others concerned in the administration of the laws (an advantage in which poor-law administration stands out distinct from any other), we must add that a consolidation of the statute law relating to poor is much needed. Dr Burn, writing a hundred and twenty years ago, spoke thus:—"If it may be reasonable to advance further still in speculation, perhaps a time may come when it shall be thought convenient to reduce all the poor laws into one. The laws concerning the poor may not improperly be compared to their apparel. When a flaw is observed, a patch is provided for it, upon that another, and so on, till the original coat is lost amidst a variety of patch-work. And more labour and materials are expended (besides the clumsiness and motley figure) than would have made an entire new suit." Since that remote day the number of statutes has increased notwithstanding a multitude of repeals. At the present time the Acts of Parliament affecting the poor laws of England alone, exclusive of Scotland and Ireland, number upwards of one hundred and thirty, and by far the greater portion of them have originated since the amendment of the poor laws in 1834.

As to poor laws in other countries, the articles devoted to those countries must be referred to. It is to be observed that legal provision is made for paupers in every part of the United States. The poor-law system which obtains in the States in its general features is similar to that which prevails in England so far as regards the mode of raising the fund (*viz.*, by way of rate) and the class of people to whom relief is afforded. Each district (commonly a town, county, or city) provides for its own poor. In some of the States paupers having no legal settlement are relieved by the State Government (1834). The prevalence

Consolidation of English poor-law desirable

of other countries

of slavery in the Southern States until its abolition modified the system of relief.

The searching inquiry into the administration of the poor laws in 1832-34 was not confined to the United Kingdom or to the States of America. Returns were obtained through the foreign ministers, and the result as to Europe is thus comprehensively stated by Nassau Senior in 1835:—"A legal claim to relief exists in Norway, Sweden, Russia, Denmark, Mecklenburg, Prussia, Würtemberg, Bavaria, and the canton of Bern, but does not exist in the Hanseatic towns, Holland, Belgium, France, Portugal, the Sardinian states, Frankfort, Venice, Greece, or Turkey." In the north of Europe the great peculiarity of the system is stated to be "the custom of affording relief by quartering the paupers on the landholders in the country and on householders in the towns." Senior arrived at the conclusion that, in those portions of the Continent in which the English principle of acknowledging in every person a right to be supported by the public existed, the compulsory relief had not, except perhaps in the canton of Bern, produced evils resembling either in intensity or extent those then experienced in the United Kingdom, and that in the majority of the nations that had adopted it the existing system appeared to work well. The poor laws of Russia, however, if they could be called poor laws, were merely parts of her system of slavery.

The absence of poor laws in France, and the charitable establishments, many of them under state management, are noticed in the article FRANCE. Senior arrived at the conclusion that the comprehensive and discriminate system of public relief established in France in relation to these institutions was not so complete as in Belgium. For the poor there see BELGIUM, where benevolent and charitable institutions and hospitals, charity workshops and depôts of mendicity or workhouses, and the *bureau de bienfaisance* are noticed. The power of expulsion *pour vagabondage* exercised as a matter of daily routine in France operates as a restraint on vagrancy, although having a wider range than the English vagrancy laws. The majority of the indigent who receive public relief in France are foreigners.

The beneficent, including eleemosynary, institutions of united Italy are treated of under that head in ITALY.

The "pauper colonies" of Holland, established in the first quarter of the present century (the first idea of which seems to have been derived from a colony of Chinese in Java), attracted public attention in England and Europe generally about the time the provision for the poor and the administration of the poor laws were under consideration, immediately before their reform in 1834. The object of the institutions in Holland was to remove those persons who were a burden to society to the poorest waste lands, where under judicious regulations they were enabled to the number of many thousands to provide for their own subsistence. It is remarkable that various schemes put forth in the 17th and 18th centuries for the reform of the British poor laws already cited team with comparisons favourable to Holland. Sir Matthew Hale refers to the industry and orderly management prevailing in Holland and Flanders. Sir J. Child and others do the like.

Among various works on poor laws see *Burn's History* and the modern work of Sir G. Nicholls; Nassau Senior's *Poor Laws of European States*; Const's and Davis's treatises; Glen's *Poor-Law Orders*; *Reports of Poor-Law Commissioners*; *Reports of Poor-Law and Local Government Boards* from 1834. (J. E. D.)

POPAYAN, a city of the republic of Colombia, capital of the state of Cauca, is situated in 2° 26' N. lat. and 76° 49' W. long., at a height of 5948 feet (E. André, 1876), on the banks of one of the head streams of the Cauca in the great plain in the heart of the cordilleras. It was founded by Belalcázar in 1538 on the site of an Indian settlement, and in 1558 it received a coat of arms from the

king of Spain and the title of "Most noble y may real." Pope Paul III. made it a bishop's see in 1547. By means of its gold mines and its share in the commerce between Quito and the valley of the Magdalena Popayan became a large and flourishing city; but political disturbances and earthquakes (1827 and 1834) have reduced it to a place of 7000 to 10,000 inhabitants (8485 in 1870). It has a cathedral built by the Jesuits, several considerable churches, two seminaries founded about 1870 by French Lazarists (who occupy and have restored the old Jesuit convent), a mint and a bank. The university was at one time celebrated; and the city is the birthplace of Caldas the astronomer and Mosquera the geographer.

The volcano of Puraco, 20 miles south-east of the town, had according to Caldas a height of 17,000 feet, but André's measurement gave only 16,192 feet. From a vent 6 feet across at a height of 14,979 feet (Boussingault, 1831), steam and gas are discharged with violence sufficient to blow a man away like a straw. On the flanks of the mountain are several hot sulphurous springs and those of Cocorono are frequented by the Colombians.

POPE is the name given in England to a small freshwater perch (*Acerina cernua*), also called RUFFE, which is generally distributed in the rivers of central Europe and common in most fresh waters of England. It was first made known by Dr Caius, a keen observer who lived in the middle of the 16th century, and is well known by his work *De Canibus Britannicis*. He found the fish in the river Yar, and figured it under the name of *Aspredo*, the Latin translation of ruffe, which name refers to the remarkable roughness of the scales with which it is covered. In general structure, shape, and habits the pope resembles much the common perch, but rarely exceeds a length of seven inches, and differs in its coloration, which is olive-brown with irregular darker spots on the body and numerous blackish dots on the dorsal and caudal fins. It is most destructive to the fry of other fish, but in many parts of the country is esteemed as food. It spawns generally in the month of April.

POPE, ALEXANDER (1688-1744), was the most famous English poet of his century. His own century dwelt most upon his merits; the 19th century is disposed rather to dwell upon his defects, both as a poet and as a man, with a persistency and minuteness that more than counterbalance any exaggeration in the estimate formed when it was the fashion to admire his verse and treat his moral obliquity as a foible. Substantially, the best judgment of the two centuries is at one, only different sides are prominent in the bulk of current criticism. All are agreed that he was not a poet of the first rank, and nobody can deny that he did certain things in literature in a way that has been the despair of all who have since attempted the same kind of thing. The great point of difference lies in the importance to be assigned to such work as Pope's satires. The polemic against his title to the name of poet would be contemptible were it not that beneath the dispute about the name there is a desire to impress on the public a respect for the highest kinds of poetry. The 19th century takes the poet's mission more seriously than the 18th. Similarly with Pope's moral delinquencies. With the exception of some details recently brought to light with an industry worthy of a better subject, his contemporaries were as well aware of these delinquencies as we are now, only none but his bitter enemies were so earnest in denouncing them. "In this design," Johnson says in his comments on the *Dunciad*, "there was perulance and malignity enough, but I cannot think it very criminal." And this was the general verdict of his contemporaries about the poet's moral weakness. They knew that he was insincere, intriguing, touchy, and spiteful, but as nobody was much harmed by his conduct, they could not think it very criminal. Perhaps his physical weakness made them

more indulgent to his elfish and sprite-like temper. But, apart from this, intriguing was the way of his world, a fact too much kept out of sight when Pope is denounced for his crooked ways in little matters, as if he had lived in our own straightforward and virtuous age.

If we are to judge Pope, whether as a man or as a poet, with human fairness, and not merely by comparison with standards of abstract perfection, there are two features of his times that must be kept steadily in view—the character of political strife in those days, and the political relations of men of letters. As long as the succession to the crown was doubtful, and political failure might mean loss of property, banishment, or death, politicians, playing for higher stakes, played more fiercely and unscrupulously than in modern days, and there was no controlling force of public opinion to keep them within the bounds of common honesty. Hence the age of Queen Anne is pre-eminently an age of intrigue. The government was almost as unsettled as in the early days of personal monarchy, and there was this difference that it was policy rather than force upon which men depended for keeping their position. Secondly, men of letters were admitted to the inner circles of intrigue as they had never been before and as they have never been since. A generation later Walpole defied them, and paid the rougher instruments that he considered sufficient for his purpose in solid coin of the realm; but Queen Anne's statesmen, whether from difference of tastes or difference of policy, paid their principal literary champions with social privileges and honourable public appointments. Hence men of letters were directly infected by the low political morality of the unsettled time. And the character of their poetry also suffered. The most prominent defects of our Augustan age in 19th-century eyes—the lack of high and sustained imagination, the genteel liking for "nature to advantage dressed," the incessant striving after wit—were fostered if not generated by the social atmosphere. The works of the serious imagination could not thrive in a fashionable society, feverishly interested in the daily chances of intrigue for place and power.

Pope was peculiarly fitted by nature to take the impress of his surroundings—plastic, sensitive, eagerly covetous of approbation. Affection and admiration were as necessary to his life as the air he breathed. "Pope was from his birth," Johnson says, "of a constitution tender and delicate, but is said to have shown remarkable gentleness and sweetness of disposition. The weakness of his body continued through his life; but the mildness of his mind perhaps ended with his childhood." Perhaps; but certainly to a much less degree with the friends who loved and honoured him. With them he was always more or less sweet and docile; his petulance and malignity were directed as by an instinct of self-preservation against those who balked him in his craving for admiration, a spiritual food literally and physically essential to the sustenance of his fragile being.

If Pope had been a man of more robust and self-sufficient constitution, he had one great advantage for resisting the spirit of his age. He was cut off by the religion of his parents from all public employment. His father was a Roman Catholic, a merchant in Lombard Street,<sup>1</sup> London, who retired from business with a small fortune in the year of the Revolution, and fixed his residence at Binfield in Wind-or Forest. Pope was born at Lombard Street on

<sup>1</sup> According to his own statement to Spence, his "Conversations" with whom are the chief authority for all the incidents of his youth. The value of the authority is much so. "He was more willing to show what his father was not than what he was," and Johnson accepted the statement that he was "a linen-draper in the Strand." Pope's vanity also renders doubtful in some details what he says about his own precocity.

May 22, 1688, but his father's retirement to Binfield took place soon after his birth. The delicate child's book education was desultory and irregular. His father's religion excluded him from the public schools, if there was no other impediment to his being sent there. Before he was twelve he got a smattering of Latin and Greek from various masters, from a priest in Hampshire, from a schoolmaster at Twyford near Winchester, from another in Marylebone, from a third at Hyde Park Corner, and finally from another priest at home. "He thought himself the better," Spence says, "in some respects for not having had a regular education. He (as he observed in particular) read originally for the sense, whereas we are taught for so many years to read only for words." This helps to explain his attack on Bentley in the *Dunciad*. He afterwards learnt French and Italian, probably to a similar extent. As far as the sense was concerned, he could get a dilution of that at least in translations, for all poets of note—Greek, Latin, French, and Italian—had been translated into English verse in the course of the previous century. Of these translations the precocious boy availed himself voraciously, and by the age of twelve, when he was finally settled at home and left to himself, he was not only a confirmed reader, but an eager aspirant to the highest honours in poetry. When at school in London he had crept into Will's coffee-house to look at Dryden; he had lampooned his schoolmaster, and made a play out of Ogilby's *Iliad* for his schoolfellows; and, thinking himself the greatest genius that ever was, he retired to the solitude of the forest to write a great epic on a mythological subject, his hero being Alexander, a prince of Rhodes.

Nothing of Pope's was printed till 1709, when he was twenty-one. The detachment from contemporary life in London which his father's religion and retirement might have occasioned was prevented by one of the accidents of that position. Fortunately or unfortunately for him, there were among the Papist families near Binfield men capable of giving a direction to his eager ambition, men of literary tastes, and connexions with the literary world. These families held together as persecuted sects always do, and the family priests were mediums of communication.

Through some such medium the retired merchant's precocious son was brought under the notice of Sir William Trumbull, a retired diplomatist living at Easthampstead, within a few miles of Binfield. At Whiteknights, near Reading, lived another Roman Catholic, Mr Englefield, "a great lover of poets and poetry." Through him Pope made the acquaintance of Wycherley and Harry Cromwell, and Wycherley introduced him to Walsh, then of great renown as a critic. Thus the aspiring poet, before he was seventeen, was admitted to the society of London "wits" and men of fashion, and he was cordially encouraged as a prodigy. It may be doubted whether the company of these veteran relics of Restoration manners was much for the benefit of the moral tone of the bookish youth, who learnt from them to speak and write of the fair sex with a very knowing air of rakish gaiety. But he discussed poetry also with them, as was then the fashion, and soon under their influence his own vague aspirations received shape and direction.

Walsh's contribution to his development was the advice to study "correctness," as the one merit that was still possible for an English poet. But before he was introduced to Walsh, which was in 1705, he had already written the first draft of his "Pastorals," a subject on which Walsh was an authority, having written the preface to Dryden's translation of Virgil's *Eclogues*. Trumbull's influence was earlier and more extensive. For him may

fairly be claimed the credit of having been Pope's school-master in poetry. It was he who turned Pope's attention to the French critics, out of the study of whom grew the *Essay on Criticism*; he suggested the subject of *Windsor Forest*, and he started the idea of translating Homer. When Trumbull first saw the precocious boy, he was hard at work on his great epic. He had probably chosen his subject on the first impulses of his crude ambition, because it was an established maxim at the time that a great epic is the greatest work of which the human mind is capable. It says something for Pope's docility at this stage that he recognized so soon that a long course of preparation was needed for such a *magnum opus*, and began steadily and patiently to discipline himself. The epic was put aside and afterwards burnt; versification was industriously practised in shorter "essays"; and an elaborate study was made of accepted critics and models. When we look at the subjects of Pope's juvenile attempts, we cannot fail to be struck by a singular clearness of purpose in his poetic ambition, such as might have come from the judgment of the accomplished man of the world who was his adviser. He not only chose kinds of poetry in which there was an interest at the time, and a consequent likelihood of gaining attention and winning applause, but he had an eye to subjects that had not already been appropriated by great English poets, and in which success was still open to all comers. At the beginning of the 18th century Dryden's success had given great vogue to translations and modernizations. The air was full of theories as to the best way of doing such things. What Dryden had touched Pope did not presume to meddle with,—Dryden was his hero and master; but there was much more of the same kind to be done. Dryden had rewritten three of the Canterbury tales; Pope tried his hand at the *Merchant's Tale*, and the *Prologue to the Wife of Bath's Tale*, and produced also an imitation of the *House of Fame*. Dryden had translated Virgil; Pope experimented on the *Thebais* of Statius, Ovid's *Heroides* and *Metamorphoses*, and the *Odyssey*. He knew little Latin and less Greek, but there were older versions in English whose metre he could improve upon and from which he could get a clue to the sense; and, when the correspondents to whom he submitted his versions pointed out mistranslations, he could answer that he had always agreed with them, but that he had deferred to the older translators against his own judgment. It was one of Pope's little vanities—very venial in a nature requiring such support—to try to give the impression that his metrical skill was more precocious even than it was, and we cannot accept his published versions of Statius and Chaucer (published in "miscellanies" at intervals between 1709 and 1714) as indisputable evidence of his proficiency at the age of fifteen or sixteen, the date, according to his own assertion, of their composition. But it is indisputable that at the age of sixteen his skill in verse was such as to astonish a veteran critic like Walsh, and that his verses were handed about in manuscript and admired by men then in the foremost rank in literature. There is no better proof of his dexterity than his imitations, or rather parodies, of Chaucer, Spencer, Rochester, and Dorset, though dexterity is their only merit. His metrical letter to Cromwell, which Mr Elwin dates in 1707, when Pope was nineteen, is also a brilliant feat of versification, and has turns of wit in it as easy and spirited as any to be found in his mature satires. Pope was twenty-one when he sent the "Ode to Solitude" to Cromwell, and said it was written before he was twelve years old. He may have retouched this; in all probability he did; perhaps every line of it was written when he was twenty-one; but there is abundance of external evidence of his extraordinary precocity

as a metrician. He was vain enough to try to make it appear still more extraordinary than it was; but the attempt was hardly more puerile and comically superfluous than the solemn efforts of criticism to reduce his pretensions. They are too solidly founded to be shaken either by his own vain superstructure or by the outraged critic's vindictive undermining.

✓Precocious Pope was, but he was also industrious; and he spent some eight or nine years in arduous and enthusiastic discipline, reading, studying, experimenting, taking the advice of some and laughing in his sleeve at the advice of others, "poetry his only business," he said, "and idleness his only pleasure," before anything of his appeared in print. In these preliminary studies he seems to have guided himself by the maxim formulated (after a French model) in a letter to Walsh (written at the date he gives, or later) that "it seems not so much the perfection of sense to say things that have never been said before, as to express those best that have been said oftenest." His first publication was his "Pastorals." Tonson the bookseller had heard these pastorals highly spoken of, and he sent a polite note to Pope asking that he might have them for one of his miscellanies. They appeared accordingly in May 1709 at the end of a volume containing contributions from Philips, Sheffield, Garth, and Rowe, besides Pope's version of Chaucer's *Merchant's Tale*. We have not space to show what can be said on both sides about these artificial compositions, avowedly designed to represent the manners of an imaginary golden age, when men of "wit and refinement" were shepherds. The worst that can be said of them was said by implication in the *Guardian* in 1713, when a case, which was afterwards justified by Allan Ramsay, was made out for the representation of real English country life. Johnson, though he did not approve of pastorals in the abstract, said a word of common sense against exaggerated depreciation of Pope's attempt. Few persons are likely nowadays to put themselves in a position for making a fair historical estimate of Pope's pastorals. There was a passing fashion for the kind of thing at the time, and possibly he wrote them under the impression that they offered a new field for poetic ambition in English, not knowing or forgetting what had been done by Giles Fletcher and Milton. Or he may have thought that a great poet should begin as Virgil began with pastorals. At any rate his pastorals, though Johnson was right in remarking the "closeness of thought" shown in their composition, cannot be ranked high as poetry, however much superior to everything else written in a passing fashion.

✓Pope's next publication was the *Essay on Criticism*. "In every work regard the writer's end," is one of its sensible precepts, and one that is often neglected by critics of the essay, who comment upon it as if Pope's end had been to produce an original and profound treatise on first principles. His aim was much less lofty—being simply to condense, methodize, and give as perfect and novel expression as he could to floating opinions about the poet's aims and methods, and the critic's duties, to "what oft was thought but ne'er so well expressed." "The town" was interested in *belles lettres*, and given to conversing on the subject; Pope's essay was simply a brilliant contribution to the fashionable conversation. The youthful author said with delicious loftiness that he did not expect the sale to be quick because "not one gentleman in sixty, even of liberal education, could understand it." But he misjudged his audience. The town was fairly dazzled by it—such learning, such comprehensiveness of judgment, such felicity of expression, was indeed a marvel in one so young. Many of its admirers, doubtless, like Lady Mary Montague, would have thought less of it if they had not

believed all the maxims to be original; but people of fashion are seldom wide readers, and they gave Pope credit for much that they might have found, where he found it, in Quintilian, Rapin, and Bossu. "The truth is," Mr Elwin says, "that Addison, by his encomiums and authority, brought into vogue the exaggerated estimate entertained of the essay." Nothing could be more preposterously far from "the truth."

A better illustration could not be found of the critical vice that Pope censures of "forming short ideas" by attending to parts to the neglect of the whole. If the whole of Addison's paper is read, it stands out in its true colours as a kindly gentle attempt to throw cold water on the enthusiasm about a work which had been published for some months and was already, as the paper admits, "highly esteemed by the best judges." It is "a masterpiece in its kind"; but people expect too much from the kind—originality, for instance. And again, it is "a masterpiece in its kind," worthy of a place beside Roscommon's *Essay on Translated Verse* and Mulgrave's *Essay on the Art of Poetry*! Most exaggerated encomiums these! How kindly, too, the paper opens by giving prominence to trivial incidents in the essay, one or two passing strokes of satire at Blackmore and Dennis. Bad poets are given to detraction; they try to raise themselves by pulling down the reputation of their brothers in the art. A third of the whole paper is devoted to warning the young poet against a spirit of envy and detraction, all because he had thrown a stone in passing at two of the common butts of their generation. But this was Addison's kindness; he wished to give the promising youth a lesson against a bad habit. Read the whole paper (*Spectator*, No. 253) and judge.

The *Rape of the Lock* in its first form appeared in 1712 in *Linton's Miscellany*; the "machinery" of sylphs and gnomes was an afterthought, and the poem was republished as we now have it early in 1714. This was his first poem written on an inspiration from real life, from nature and not from books. A gentleman had in a frolic surreptitiously cut off a lock of a young lady's hair, and the liberty had been resented; Pope heard the story from his friend Caryl, who suggested that it might be a subject for a mock-heroic poem like Boileau's *Lutrin*. Pope caught at the hint; the mock-heroic treatment of the pretty frivolities of fashionable life just suited his freakish sprightliness of wit, and his studies of the grand epic at the time put him in excellent vein. The *Rape of the Lock* is almost universally admitted to be his masterpiece. English critics from his own time to the present have competed in lauding its airiness, its ingenuity, its exquisite finish. But M. Taine's criticism shows how much depends upon the spirit in which such humorous trifles are approached. The poem strikes M. Taine as a piece of harsh, scornful, indelicate buffoonery, a mere succession of oddities and contrasts, of expressive figures unexpected and grinning, an example of English insensibility to French sweetness and refinement. Mr Leslie Stephen objects on somewhat different grounds to the poet's tone towards women. What especially offends the French critic's delicate sense is the bearishness of Pope's laughter at an elegant and beautiful woman of fashion. Pope describes with a grin of amusement all the particulars of the elaborate toilet with which Belinda prepared her beauty for conquest, and all the artificial airs and graces with which she sought to bewitch the heart of susceptible man. The Frenchman listens without sympathy, without appreciation, with the contemptuous wonder of a well-bred man at clownish buffoonery. What is there to laugh at? Is she not preparing a beautiful picture? She cannot do this without powders and washes and paint-pots. What

is there to laugh at in this? It is mere matter of fact. The entire surrender of the female heart to little artifices for little ends does not apparently strike the Frenchman as ludicrous. Mr Stephen's laughter is checked by the serious thought that this is a misrepresentation of women, that women are spoken of in the poem as if they were all like Belinda. But the Frenchman is not moved to laughter at all; it would seem as if his delight in the finished picture, the elegant graceful captivating woman, hallowed every ingredient used in the making of it. Such are the differences in national humour. With English readers the change of manners since the fashionable party rowed up the river to spend a happy day at Hampton is more likely to be an obstacle to the enjoyment of Pope's airy extravagance.

In the interval between the first and the enlarged edition of the *Rape of the Lock*, Pope gave the finishing touches to his *Windsor Forest*, and published it in March 1713, with a flattering dedication to the secretary at war and an opportune allusion to the peace of Utrecht. This was a nearer approach to taking a political side than Pope had yet made. His principle had been to keep clear of politics, and not to attach himself to any of the sets into which literary men were divided by party. Although inclined to the Jacobite party by his religion, he was on friendly terms with the Whig coterie, so friendly indeed as to offend some of his co-religionists. He had contributed his poem "The Messiah" to the *Spectator*; he had written an article or two in the *Guardian*; and he wrote a prologue for Addison's *Cato*. But Pope's advances had not been received in a way to satisfy a man of his petulant and exacting temper. Mr Elwin is much mistaken in supposing that Addison helped to bring Pope into notice in the *Spectator*. We have seen how he treated the *Essay on Criticism*. When the *Rape of the Lock* was published, Addison is said to have praised it to Pope himself as *merum sal*, but he was much more guarded in the *Spectator*. There he dismissed one of the gems of English literature with two sentences of patronizing faint praise to the young poet whom he rejoiced to see getting on, coupled it with Tickell's "Ode on the Prospect of Peace," and devoted the rest of the article to an elaborate puff of "the pastorals of Mr Phillips." We have only to look at the shameless puffery of the members of the little senate, not only in this article but throughout all the periodicals of the coterie, to see how little the young Mr Pope owed to Addison.

When Pope showed a leaning to the Tories in *Windsor Forest*, the coterie, so far from helping him, made insidious war on him—not open war but underhand war. Within a few weeks of the publication of the poem, and when it was the talk of the town, there began to appear in the *Guardian* a series of articles on "Pastorals." Not a word was said about *Windsor Forest*, but everybody knew to what the general principles referred. Modern pastoral poets were ridiculed for introducing Greek moral deities, Greek flowers and fruits, Greek names of shepherds, Greek sports and customs and religious rites. They ought to make use of English rural mythology—hobthrushes, fairies, goblins, and witches; they should give English names to their shepherds; they should mention flowers indigenous to English climate and soil; and they should introduce English proverbial sayings, dress, and customs. All excellent principles, and all neglected by Pope in *Windsor Forest*. The poem was fairly open to criticism in these points; there are many beautiful passages in it, showing close though somewhat professional observation of nature, but the mixture of heathen deities and conventional archaic fancies with modern realities is incongruous, and the comparison of Queen Anne to Diana was ludicrously

to use Wordsworth's phrase, "when the heights were within his reach"? His choice was determined partly by character and partly by circumstances. It may be doubted whether Pope had the staying power necessary for the composition of a great imaginative work, whether his crazy constitution would have held together through the strain. He toyed with the idea of writing a grand epic. He told Spence that he had it all in his head, and gave him a vague (and it must be admitted not very promising) sketch of the subject and plan of it. But he never put any of it on paper. He shrank as with instinctive repulsion from the stress and strain of complicated designs. Even his prolonged task of translating weighed heavily on his spirits, and this was a much less formidable effort than creating an epic. He turned rather to designs that could be accomplished in detail, works of which the parts could be separately laboured at and put together with patient care, into which happy thoughts could be fitted that had been struck out at odd moments and in ordinary levels of feeling.

The *Dunciad* (1728) was the first work of the new period. Circumstances turned him to satire when he was free from the *Odyssey*, and from his edition of Shakespeare, a bookseller's commission completed in the same year. Young's satire, *The Universal Passion*, had just appeared and been received with more enthusiasm than anything published since Pope's own early successes. This alone would have been powerful inducement to Pope's emulous temper. Swift was finishing *Gulliver's Travels*, and came over to England in 1726. The survivors of the Scriblerus Club—Swift, Pope, Arbuthnot, and Gay—resumed their old amusement of parodying and otherwise ridiculing bad writers, especially bad writers in the Whig interest. A volume of their *jeux d'esprit* was published in 1727. According to Pope's own history of the *Dunciad*, the idea of it grew out of this. Among the miscellanies was a "Treatise on the Art of Sinking," in which poets were classified, with illustrations, according to their eminence in the various arts of debasing instead of elevating their subject. No names were mentioned, but the specimens of bathos were assigned to various letters of the alphabet, most of them taken at random. But no sooner was the treatise published than the infatuated scribblers proceeded to take the letters to themselves, and in revenge to fill the newspapers with the most abusive falsehoods and scurrilities they could possibly devise. "This gave Mr Pope the thought that he had now some opportunity of doing good, by detecting and dragging into light these common enemies of mankind," who for years had been anonymously aspersing almost all the great characters of the age.

The truth probably lies between this account and that adopted by those who take the worst view of Pope's character. This is that he was essentially vindictive and malignant, and that, as soon as his hands were free from Homer, he proceeded to settle old scores with all who had not spoken as favourably as he liked about himself and his works. The most prominent objects of his satire can be shown to have given him personal offence—Theobald, Cibber, Dennis, Lintot, and others. This indeed was avowed by Pope, who claimed that it was their attacks on himself that had given him a right to their names. We may admit that personal spite influenced Pope at least as much as disinterested zeal for the honour of literature, but in the dispute as to the comparative strength of these motives, a third is apt to be overlooked that was probably stronger than either. This was an unscrupulous selfish love of fun, and delight in the creations of a humorous imagination. Certainly to represent the *Dunciad* as the outcome of mere personal spite is to give an exaggerated

idea of the malignity of Pope's disposition, and an utterly wrong impression of the character of his satire. He was not a morose, savage, indignant satirist, but airy and graceful in his malice, writing more in fun than in anger, revengeful perhaps and excessively sensitive, but restored to good-humour as he thought over his wrongs by the ludicrous conceptions with which he invested his adversaries. We do not feel the bitterness of wounded pride in his writings, but the laughter with which that pride was consoled. He loved his own comic fancies more than he hated his enemies. His fun at the expense of his victims was so far cruel that he was quite regardless of their sufferings, probably enjoyed them; but it was an impish and sprite-like cruelty, against which we cannot feel any real indignation because it is substantially harmless, while its ingenious antics never fail to amuse. Even when he exults in the poverty and material distresses of his victims, the coarseness of the matter is redeemed by the irresponsible gaiety of the manner. Such things should not be taken too seriously, if a Scotsman may say so. Further, even if Pope is regarded as a bitter malignant, it must be with two important qualifications. His plea that he was never the aggressor in a quarrel, in spite of all Mr Elwin's special pleadings to the contrary, was a truthful plea, though his sensitiveness to criticism was such as to make him fancy slights, and the withholding of praise where praise was due would have been construed by him as a positive offence. And his literary conscience was so strong that not one of his attacks on literary grounds was unjust. Pope was a most generous critic of real merit. The only doubtful exception is the case of Bentley, whom he satirized in the reconstruction and enlargement of the *Dunciad* made in the last years of his life at the instigation, it is said, of Warburton. Looked at apart from personal questions, the *Dunciad* is the greatest feat of the humorous imagination in English poetry.

There was much more of unjust judgment in Pope's *Satires and Epistles of Horace Imitated*, published at intervals between 1733 and 1738, because in them he oftener wrote of what he did not personally know, and was the mouthpiece of the animus of his political friends. These friends were all in opposition to Walpole, who was then at the height of his power, and the shafts of Pope's satire were directed at the adherents of the great minister. Pope's satires give the concentrated essence of the bitterness of the opposition. We see gathered up in them the worst that was thought and said about the court party when men's minds were heated almost to the point of civil war. To appreciate fully the point of his allusions requires of course an intimate acquaintance with the political and social gossip of the time. But apart from their value as a brilliant strongly-coloured picture of the time Pope's satires have a permanent value as literature. It is justly remarked by Pattison<sup>1</sup> that "these *Imitations* are among the most original of his writings." The felicity of the versification and the diction is universally admired.

The *Essay on Man* (1732-34) was also intimately connected with passing controversies.<sup>2</sup> It belongs to the same intellectual movement with Butler's *Analogy*—the effort of the 18th century to put religion on a rational basis. But Pope was not a thinker like Butler. The subject was suggested to him by Bolingbroke, who is said also—and the statement is supported by the contents of his posthumous works—to have furnished most of the arguments. Pope's contribution to the controversy consisted in brilliant epigram and illustration. In this di-

<sup>1</sup> In his incomparable edition of the *Satires and Epistles*.

<sup>2</sup> See Pattison's edition of the *Essay on Man*.

dactic work, as in his *Essay on Criticism*, he put together on a sufficiently simple plan a series of happy sayings, separately elaborated, picking up the thoughts as he found them in miscellaneous reading and conversation, and trying only to fit them with perfect expression. The want of logical coherence in his system was shown by the very different interpretations put upon it. Dealing as it did in incomparably brilliant fashion with a subject of living interest, the *Essay* at once attracted attention both at home and abroad, and Pope was attacked by a Swiss professor as an ally of the freethinkers. But a champion of his orthodoxy was found in Warburton. Pope was so delighted with the pugnacious paradoxist's reply to De Crousaz that he made Warburton's acquaintance. The readiness with which Pope allowed Warburton to take possession of himself and his works in his old age was not a symptom of senile weakness. It was an act of that characteristic business-like acuteness which he showed throughout in the management of his reputation. He saw that as long as Warburton was the authorized commentator on his works there was not likely to be any lack of critical debate about him and about them.

The *Essay on Man*, which may be said to contain the essence of the thought of men of the world in his generation on its subject—such was the poet's skill and judgment in collecting the substance of floating opinion—was announced by Pope as part of a system of "pieces on human life and manners." Whether Warburton was authorized or not in his sketch of Pope's intentions, the so-called *Moral Essays* (published at intervals between 1731 and 1735) which Warburton connected with the general plan have each an independent interest. They contain some of the most brilliant of Pope's satirical portraits, and his famous theory of "the ruling passion." If space permitted it might easily be shown that in this theory Pope proved himself a better psychologist than Macaulay, who subjects it to much misunderstanding and ridicule.

Pope died on the 30th May 1744, and was buried in the church of Twickenham. His own ruling passion was what a poet of his generation described as the universal passion, the love of fame. Under the influence of this passion he tried to support his reputation by intrigues such as the statesmen of his time used in climbing the ladder and keeping themselves in place. He had no moral scruple where this was concerned—everything gave way before the ruling passion. For some of these intrigues, so incongruous with our idea of a poet's character, he has suffered severe retribution. Especially of late years he has been violently denounced as little better than a common swindler for his petty manoeuvres in connexion with the publication of his letters—letters designed to exhibit him as a pattern of friendship, magnanimity, and all the virtues. These manoeuvres, which were first tracked with great patience and ingenuity by Mr Dilke,<sup>1</sup> are too intricate to be recorded in short space. This, in effect, is what he seems to have done. He collected his letters from his friends, retouched them, changed dates and passages to suit the picture of himself which he wished to present, deposited the collection thus manipulated in the safe-keeping of the earl of Oxford, then sent a printed book of them to Curll, and intrigued to make it appear that they had been fraudulently published without his consent. It was a ridiculously petty action, but to characterize it as Mr Elwin has done will be fair when it is customary to use similar language about the intrigues of statesmen and diplomatists. To apply it to Pope at present is not to call a spade a spade, but a molehill a mountain. Recent revelations have not affected by one iota Johnson's judgment of his character. The man who

"played the politician about cabbages and turnips," and "hardly drank tea without a stratagem," was not likely to be straightforward in a matter in which his ruling passion was concerned. Against Pope's petulance and "general love of secrecy and cunning" have to be set, in any fair judgment of his character, his exemplary conduct as a son, the affection with which he was regarded in his own circle of intimates, and many well-authenticated instances of genuine kindness to persons in distress. (W. M.)

POPEDOM.<sup>2</sup> Both the ecclesiastical and the temporal authority formerly exercised and still claimed by the popes of Rome profess to be of divine appointment, appealing in the first place to the language of the New Testament, and in the next to the tradition of the church, handed down, as it is asserted, in unbroken continuity from apostolic times to the present age. According to the theory thus put forth, Peter the apostle was indicated by Christ Himself as superior to the rest of the twelve in faith and spiritual discernment, and as the one of the number whom it was His design to invest with special pre-eminence. In like manner, the church itself which Peter was afterwards to found and to preside over was predestined to a like superiority among other churches, while his personal superiority was to be vested in perpetuity in his successors. In conformity with this divine design Peter, accompanied by Paul, went to Rome after Christ's death, and founded there a church over which he presided as its bishop for twenty-five years,—from the first year of the reign of Claudius, 41 A.D., to 67 A.D.,—eventually suffering martyrdom in the same year and on the same day as St Paul, in the persecution under Nero. And, if we accept the records preserved in the Roman Church, we shall believe that St Peter's successors, so long as Christianity was the object of state persecution, continued heroically to encounter the same glorious fate, the distinction of martyrdom being assigned in the Roman calendar to all but two of the bishops of Rome from Linus to Eusebius (see list at conclusion of article).

In dealing with a subject in which the evidence is frequently ambiguous and conflicting, and sometimes of more than doubtful genuineness, and with a period of much obscurity, no amount of research will often serve to point to more than a conjectural conclusion. But, inasmuch as it is on the basis of the assumptions involved in the above theory that the claims of the Church of Rome mainly rest, it will be desirable to state, as concisely as possible, the main facts and arguments on which those who deny these assumptions ground their contrary opinion.

The question whether or no St Peter was designed for pre-eminence among the apostles resolves itself, it is evident, into one of New Testament criticism; but from the time of Origen, who visited Rome early in the 3d century, when the theory first began to be put forward, there has always been a certain section in the church who have distinctly repudiated the affirmative assumption. "For if," says Origen, "you hold that the whole church was built by God on Peter alone, what will you say concerning John, the son of thunder, and each of the other apostles?" (Migne, *Patrologia Græca*, xiii. 397). Next, as regards the evidence for St Peter's presence in Rome, and lengthened labours there, as the head of a Christian congregation, it is maintained by the great majority of Protestant scholars that there is no proof that he was ever in Rome at all; that the "Babylon" referred to in his first epistle (ch. v. 13) is really the distant city of the

<sup>2</sup> The design of the present article is simply to give the main outlines of the history of the Papacy as an institution; the details connected with the personal history of each pontiff will be found under the respective names of the different popes. The dates immediately after the name of each pope denote the period of his pontificate.

East; and that, even if his presence in Rome be admitted, his arrival there must have been long subsequent to that of his brother apostle, and his labours altogether subordinate in importance,—conclusions supported by the complete silence observed in the Acts of the Apostles respecting both him and his work in the capital of the empire. On the other hand, it is urged that, as no known tradition assigns the martyrdom of Peter to any other place than Rome, every allusion to that event is implicitly an argument for his visit to the capital; and, generally speaking, it may be said that the most recent and authoritative research seems to point to the conclusion that he both visited Rome and taught there, but that his labours were carried on in a spirit of rivalry, not to say antagonism, to those of Paul, being bestowed exclusively on a Judaizing church, while those of his fellow-apostle were devoted to the Gentile community. Of the important feature which harmonizes perfectly with these conclusions—namely, that the Church of Rome, attaching itself directly to the church at Jerusalem, became the depository of a Jewish-Christian rather than of a Pauline tradition—there can be no doubt whatever.

The Jews at Rome. The existence of a considerable poor Jewish element in Rome as early as the latter half of the 1st century is attested by numerous facts and allusions in the classical writers. The Jews were everywhere actively engaged in commercial pursuits, and formed an influential section in all great centres. Josephus tells us that, when on one occasion the Jews of Palestine presented a petition to the emperor Augustus, it was supported by no less than eight thousand of their countrymen resident in the capital. The chief quarters of this Jewish colony were in the Trastevere, about the base of the Janiculum; and its members were distinguished by the fidelity with which they cherished their national customs and beliefs. Both Rome and the Jewish community in its midst must accordingly have appeared a field of primary importance in the work of evangelization; and it is evident that the questions raised by the claims of Christianity would there be discussed with the greatest ardour, and the most strenuous endeavours be made to bring them to an ultimate issue. That such was really the case is sufficiently proved by a well-known passage in Suetonius, who relates that about the middle of the 1st century there were constant riots among the Jewish population, their ringleader being one "Chrestus," and that Claudius in consequence expelled them from the city. There is no reason for supposing that this section of the community would be estranged to any great degree, by the pursuits and associations of their daily life, from those by whom they were surrounded. The influences that then pervaded alike the Roman literature, culture, and civilization were mainly Greek, and the Jewish element was no less affected by these influences than the Latin. Greek, again, was the ordinary medium of commercial intercourse throughout the Roman world, and the Jew was largely engaged in commerce. Greek therefore had, except in the Syrian provinces, become the language of his daily life, as it had long been that of his sacred books read aloud in the synagogues, and of the annals of his race as recorded by the national writers.

The importance of the passage above referred to in Suetonius, of which the very inaccuracy which it embodies is in itself highly significant, has perhaps hardly been sufficiently recognized, for it not only records an important fact but it sheds light on subsequent history. It enables us to understand that, when the Jewish population was permitted to return to Rome, its members, whether adherents of the national faith or converts to the new, would, in common with the whole Christian community,

feel the necessity of extreme caution lest their religious observances or their religious differences should again attract the notice of the Roman magistrate and expose them to fresh persecution. Of this character would appear to be the sentiments indicated in the epistle of Clemens Romanus (supposed by some to have been the same with the Clemens whose name is inserted as that of the third bishop of Rome) when he refers to the sudden and repeated "calamities and adversities which are befalling us"—a passage generally interpreted as having reference to the persecution under Nero and the impending persecution under Domitian (Lightfoot, *Append.*, p. 267). In such considerations as these we may fairly consider that we have a reasonable explanation of the fact that during the first two centuries of its existence we hear so little of the Christian church in Rome.

With such considerations before us, it is scarcely necessary to point out that Greek was also the language of the early Christian church in Rome. In whatever proportions, therefore, that church was composed of Christianized Jews or of Christianized pagans, its records would naturally be, as we find them to have been, in the Greek language. Hegesippus, "the father of church history," makes a statement which is generally understood to imply that, being in Rome in the time of Anicetus (bishop 155<sup>1</sup>–168 A.D.), he made a list of the bishops of the see. This list is not extant; but in Irenæus, who wrote his *Adversus Hæreses* a few years later, we have another Greek list of twelve bishops, which shows the succession accepted at Rome in the time of Eleutherius, the contemporary of Irenæus, and at the head of which stand the names of both Peter and Paul. To these lists are to be added two other Greek lists, the one in the *Chronicon* of Eusebius, the other in the *Ecclesiastical History* of the same writer. Of these, the former extends from Peter to Gaius (the last bishop before the Diocletian persecution), and gives the periods of office. It is derived from the Armenian translation, but is not contained in the version by Jerome. The first Latin list, the *Catalogus Liberianus*,—supposed by Mommsen to have been derived from the *Chronicon* of Hippolytus, bishop of Portus, and to have been in turn the original from which the *Catalogus Felicianus* (the oldest existing version of the *Liber Pontificalis*,—see *infra*) was taken,—is so called because it was compiled in the episcopate of Liberius, who succeeded 352 A.D. We have also two other Latin lists of some authority, in Augustine (*Epist.* 53; Migne, *Patrol.*, xxxiii. 195) and in Optatus (*De Schism. Don.*, ii. 3).

It is undeniable that in all the foregoing lists there are considerable discrepancies. The Liberian catalogue gives us a certain "Cletus," as the immediate predecessor of Anaclethus; scholars like Mommsen and Lipsius are divided in opinion as to whether Anicetus was the predecessor or the successor of Pius; while, as regards the duration of each episcopate, there are equally important discrepancies. But difficulties like these cannot justly prejudice our acceptance of the general tradition with which they are associated; they are rather to be looked upon as supplying valuable incidental evidence with respect to the status of the Roman episcopate; and, while the lists themselves prove, on the one hand, that before the termination of the 3d century the office was held to be of such importance that its succession was a matter of interest to ecclesiastics living in distant sees, the variations that the lists present indicate not less clearly that the Roman bishopric at this period could not have held that position in relation to the church—the parallel to that of the

<sup>1</sup> For this date see article "Pope" in Smith's *Dict. of Christian Antiquities*, p. 1657.

Earliest lists of the Roman bishops.

imperial office in the empire—claimed for it by writers like Bellarmine.

The comparative history of institutions would, in itself, incline us to look for a less precise and exalted conception of the office, as discharged by these early bishops, than when, after a lapse of centuries and a succession of varied experiences, its duties and responsibilities had become defined and developed: but it is also a fact of considerable significance that those who were elected to the office from the time of Clement were for the most part men whose very names would probably not have survived but for their appearance in these lists, and that, even when, in one or two instances, their individual careers emerge from the general obscurity, they themselves appear as speaking and acting in a manner which seems hardly compatible with those exalted prerogatives which, as some maintain, were inherent in the office from its first commencement. In

the recently recovered portion of the epistle of Clement Romanus, above cited, it is, for example, highly significant to find that the letter purports to emanate, not from the "bishop of Rome," but from "the church at Rome," and to find again that, even so late as the 2d century, this letter is in like manner referred to as emanating from the community, and not from the individual. This feature, indeed, is not a little suggestive with respect to the development of the Roman supremacy. While the letter is wanting in anything that implies any special pre-eminence on the part of the Roman bishop, it is at the same time characterized by a certain admonitory tone, such as could hardly have been assumed if the community by whom it was sent had not been held to possess a recognized superiority over the community to whom it is written, but this superiority is not greater than would naturally belong (notwithstanding their common founder) to the church in imperial Rome as contrasted with the church at subject Corinth.—to the church of the august capital from whence emanated the laws which governed the empire and the church of the fallen city which, two centuries and a half before, the Roman arms had well nigh effaced from existence.
